as from letters to figures. For this purpose the periphery of the type wheel is arranged with the desired different signs thereon in alternate order, and this wheel is affixed to a hollow shaft or boss which receives the hollow shaft or boss of a correcting or adjusting wheel having teeth on its periphery corresponding with those of one set of signs on the type wheel or the intermediate portions thereof. The outer end of an arm from the axis of the type wheel passes into a recess in a lever turning upon an axis carried by the correcting or adjusting wheel, and this wheel is formed at its opposite ends with projections adapted respectively to fill up spaces opposite those between the teeth of the correcting or adjusting wheel. The pressing in of one end of this lever will cause the teeth of the correcting or adjusting wheel to be coincident with one set of signs on the type wheel, and the pressing in of the opposite end of the lever causes the type wheel to be moved partly round on its axis, so that intermediate signs are then coincident with the teeth of the correcting or adjusting wheel. One or the other end of this lever is pressed inwards at the times desired to effect a change, when the apparatus is set in motion by the passage of a current of electricity brought into operation by acting on one or the other of particular keys corresponding with the relative position of the type and correcting or regulating wheels. The improvements relate —3, when using the power of a permanent magnet in connection with an electro-magnet, in manner of the character described in the specification of letters patent granted respectively to Joseph Camp Griffith Kennedy, bearing date the 11th day of September, 1855, No. 2058, and to the present patentee bearing date the 27th day of April, 1858, No. 938—and consist in connecting the armature through a small local battery to one wire of the electro-magnet, and in connecting the other wire of the electro-magnet with a stud or projection in position to be acted upon by the armature when that is raised. By these means, upon the passage of a current of electricity into the electro-magnet, the armature is at once released, when the current of electricity, in place of continuing through the coils of the electro-magnet, flows by way of the armature, and through the local battery, to the main wire, at the same time the tendency of the local battery is to restore the magnetism in the cores of the electro-magnet. *Patent completed.*

242. W. C. WILKINS. *Improvements in lamps.* Dated January 27, 1863.

To a lamp constructed with a reservoir in its stem or base to contain the matter to be burned, and means for forcing up such matter for consumption, the inventor applies between such reservoir and the burner a small vessel of porcelain, glass, or other suitable material that will not freely conduct heat up to the burner; and he applies cork or other suitable non-conducting material between the upper parts of a receiver and the burner tubes, acting as a receiver for or feed to the lower part of the wick and of the fluid being consumed. This receiver has an overflow for surplus fluid to flow back into the reservoir below. He also applies an internal hollow cone, and an external tubular deflector, the upper or deflecting edge thereof being turned inwards, and at or near the level of the wick tubes, which external deflector he prefers to be of glass, so as to intercept the rays of light as little as possible; over these he applies an external chimney. *Patent abandoned.*

243. H. B. BARLOW. *Improvements in preserving timber, and in apparatus employed therein.* (A communication.) Dated January 28, 1863.

This invention consists in placing the timber in a closed vessel, from which the air is exhausted by suitable air-pump machinery, then subjecting it to the action of a metallic salt, and then to the action of tar or other bituminous substance. *Patent completed.*

244. H. WATSON. *Improvements in the heating arrangements of stoves for drying woven fabrics.* Dated January 28, 1863.

These improvements are advantageously applicable to stoves of the kind used for Turkey-red fabrics. A stove of this kind consists of a building of one, two, or more storeys or flats; the floors in the case of two or more flats being permeable to the heated air or vapour. The heat is applied to the bottom or ground floor by means of a horizontal flue proceeding from a furnace at one end, and returning backwards and forwards across or along the floor a number of times until it finally reaches the chimney or stack. As hitherto arranged, the heat radiated in a downward direction is completely lost, and it is the object of the present invention to recover and utilize a large portion of that otherwise waste heat by constructing under the main flue an air flue or passage discharging itself into the main flue behind the fire-bridge, or at any other suitable point or points. *Patent abandoned.*

245. T. PANKINSON. *Improvements in carding engines.* Dated January 28, 1863.

This invention has for its object the combing of the cotton from the doffers of the machines known as carding engines, and consists in attaching the comb by means of two or more arms or levers to an oscillating shaft, which receives motion from a revolving shaft containing a crank or eccentric by means of a rod and lever. This revolving shaft has motion given to it by wheelwork, either direct from the shaft which drives the delivery rollers, or from the driving wheels connected thereto; or it may be driven by bands and pulleys from any convenient part of the machine. The revolving shaft actuates the oscillating shaft by means of the said crank or eccentric and a rod or lever, thereby giving the comb an oscillating motion, so as to remove the cotton from the doffer. *Patent abandoned.*

246. W. E. GEDGE. *Improved machinery or apparatus for fastening by screws boots, shoes, and other articles composed of leather.* (A communication.) Dated January 28, 1863.

This invention is not described apart from the drawings. *Patent completed.*

247. E. F. PRENTISS and J. C. SELLARS. *Improvements in treating rock oil, petroleum, paraffine oil, coal oil, and other like mineral oils and products therefrom.* Dated January 28, 1863.

This invention has for its object an improved system of treating petroleum or rock oil, paraffine oil, coal oil, paraffine, and other like mineral oils, and the products therefrom, and consists in combining them with resin, resinous, or other gums, and tallow and other fatty matter, to improve the quality of these substances, to better adapt them for burning, lubricating, detergent, and other purposes. When required for detergent purposes, it is preferred to saponify the compounds by the addition of any of the alkaline substances used for that purpose. *Patent abandoned.*

248. J. OGLESBY, J., W. M., and J. DICKINSON, jun. *Improvements in apparatus for steaming, cooking, and generating gas.* Dated January 28, 1863.

This invention is not described apart from the drawings. *Patent completed.*

249. H. O. COOK and E. G. TERREY. *Improvements in propelling ships and vessels, and in apparatus employed therein.* Dated January 28, 1863.

The patentees claim a method of propelling vessels by means of rotating fan or windmill sails, in connection with certain gearing, and a screw propeller or paddle wheels, substantially in the manner specified. *Patent completed.*

250. C. MACE. *Improvements in steam engines for propelling vessels and for other purposes.* Dated January 28, 1863.

The main bed of this engine is formed into a hollow box frame of a suitable form, and of sufficient size to receive the arrangement of horizontal tubes of a surface condenser. In this condenser the tubes are placed horizontally, but slightly inclined, and the tubes in each are disposed in a line with the keel (when used for ship propulsion) and, consequently, with the driving shaft of the engine. It is preferred that the circulation of the condensing water should be by mechanical means, and through the thin metal tubes of the condenser, whilst the steam is brought in contact with the exterior surface of such tubes; but this action may be reversed. The condensers form the bed of the engine, and the hollow columns which rise above and are fixed to the condensers, form the supports of the cylinders. The air-pumps are formed in the columns that support the cylinder, and are worked from cross-heads either above or below the cylinders; the pump rods work through suitable stuffing-boxes. *Patent completed.*

251. R. WARD. *Improvements in locking-up or fastening forms of type or other printing surfaces.* Dated January 28, 1863.

In place of a series of "quoins" or loose wooden wedges acting upon a "side-stick" or "foot-stick," the patentee employs two (though it is not absolutely necessary to use two, as the result may be accomplished by one) side-sticks or foot-sticks, with their bevelled edges turned towards each other, and between these he places a continuous wedge (or a series of united wedges forming one piece) of iron, or other suitable material or materials, which is fixed and kept in its place by means of a screw acting upon a square or suitably-shaped piece of iron placed in the corner of the chase, so that it will bear the pressure of the screws of both the bottom and the side wedges. *Patent completed.*

252. F. W. WYMER. *Improvements in steam engines.* Dated January 28, 1863.

For the purposes of this invention, two cylinders are used—one, the smaller cylinder, is a high-pressure cylinder, whilst the other, the larger cylinder, is a low-pressure cylinder—combined in such manner that the steam from the high-pressure cylinder is passed into and expanded in the larger cylinder, as is well understood. It is preferred that the larger cylinder should be the lower one of the two, and that the smaller cylinder should be formed on the upper end or cover of the larger cylinder. The piston rod of the smaller cylinder passes through a stuffing-box in the cover of that cylinder, and is fixed to the middle of a cross-head. The piston in the lower and the larger cylinder has two piston rods which respectively work through stuffing-boxes formed in the upper end cover of the larger cylinder, in such manner that the piston rods are outside of the smaller cylinder, and their ends are fixed to the ends of the cross-head above mentioned. There are also two piston rods to the piston of the larger cylinder, which descend through the lower end cover, and work through stuffing-boxes formed therein. The lower ends of these two piston rods are fixed to a cross-head, the ends of which slide or move between guides fixed to the columns or hollow supports on which the larger cylinder is fixed. These columns or hollow supports are to be constructed and arranged in a suitable manner to act as condensers, either by injection or surface condensation. The hollow columns or supports are fixed to a suitable bed plate, and the main or driving shaft of the engine is placed between the columns or hollow supports. Motion is communicated to the driving shaft by means of a connecting rod from the lower cross-head, from which also motion is communicated by a beam or lever to the air and water pumps, which are, by preference, arranged on the base plate outside of the columns or hollow supports. *Patent completed.*

253. J. PLATT. *Improvements in rotary engines.* Dated January 28, 1863.

For the purposes of this invention, a cylinder is mounted and fixed to an axis or shaft by means of one of its ends or covers. The cylinder is placed within a cylindrical or other suitable form of cover or case, which is arranged to act as a framing. It is preferred that this case should be constantly full of steam when the engine is being worked by steam. Part of the shaft or axis, and the cylinder thereon, are arranged to rotate with the case or cover, whilst parts of the shaft or axis pass through and are supported in suitable bearings at each end of the cover or case. One of the end covers of the cylinder is made with two hollow chambers, one on each side of the shaft or axis, to receive two slides which are alternately moved into and out of the cylinder of the engine by means of a stationary fixed undulating track or cam, in which a roller at the end of each of the slide rods moves. The undulating track or cam is fixed to a hollow trunk, which passes from the exterior into the interior of the case, its inner end coming against the end cover of the cylinder of the engine, which is fixed to the shaft or axis. The hollow trunk is divided into two parts or compartments; one acts as the steam pipe or passage for conveying steam to the interior of the cylinder of the engine when the engine is worked by steam, and the other compartment constitutes the steam outlet from the cylinder of the engine; but the use of these two compartments or divisions of the hollow trunk may be changed or reversed by a suitable slide or other valve. A steam stop is formed or fixed in the end of the hollow trunk, which forms a steam abutment within the cylinder of the engine, and it is between this fixed stop or abutment and one of the slides the steam is introduced into the cylinder of the engine, whilst the steam is allowed to escape from the cylinder of the engine into the outlet compartment on the other side of the slide. The slides, as they pass the abutment or stop, are by the cam or undulating track caused to enter the cylinder in such a manner as to be acted on by the steam, and to be propelled thereby from the steam stop or abutment, so as to communicate a rotary motion to the cylinder and the axis or shaft of the engine to which the cylinder is fixed. The steam or abutment is packed with metallic packing formed with inclined surfaces, which packing is capable of being set up by a screw, which can be turned from the outside of the case. The engine may be worked by other fluid as well as by steam; and by applying power to the shaft or axis, so as to give a rotary motion to the cylinder, the engine will become a pump. *Patent completed.*

254. W. CONISBEE. *Improvements in cylindrical chromo-lithographic printing machines.* Dated January 28, 1863.

This invention is not described apart from the drawings. *Patent completed.*

255. S. W. FRANCIS. *Improvements in revolving shutters.* Dated January 28, 1863.

These improvements consist in so constructing the laths or plates of revolving shutters that such shutters may revolve in either direction round the roller to which they are attached; and for this purpose the patentee forms a groove in the bottom or lower edge of each lath or plate, and along the entire length of each lath or plate of which the shutter is composed (except the bottom lath of each shutter), and he constructs the upper edge of such lath or plate thinner than the lower edge thereof to fit into the groove in the lower edge of the lath or plate immediately above it. He then unites the several laths or plates of which the shutter is composed by means of belts, webs, chains, cords, or wires, passed through holes or mortises in the breadth of each lath or plate in the usual manner. *Patent completed.*

256. W. CLARK. *Improvements in the means and apparatus for copying and reproducing sculpture and other objects of art.* (A communication.) Dated January 28, 1863.

This invention relates to an improved process termed photo-sculpture, which is based on the employment of photography in connection with the pantograph. By this improved process the patentee can produce sculpture exactly similar to the model, whether living or otherwise, with much greater rapidity, at a less cost, and by the aid of persons having no previous knowledge of the art. He can further lessen the time necessary for the sitting, and produce sculpture of larger or smaller dimensions than the original, or in any other proportions desired. This invention cannot be described without reference to the drawings. *Patent completed.*

257. J. H. JOHNSON. *Improvements in the manufacture of braid, and in machinery or apparatus employed therein.* (A communication.) Dated January 28, 1863.

This invention relates—1, to an improved manufacture of flat braid, and consists in making such braid with the borders or selvages thinner than the body or central portion thereof. The second portion of this invention relates to certain peculiar constructions and combinations of parts of braiding machines, whereby the productive powers are greatly increased, whilst the work executed is superior to that produced in ordinary braiding machines. According to this part of the invention, it is proposed to make the spindles or bobbin carriers in such a manner as to admit of the bobbins being easily lifted off with such parts as hold the threads in their different directions without disturbing such threads, whereby facility is afforded for changing a deranged bobbin by simply replacing it by one in perfect order. *Patent completed.*

258. C. P. STEWART and J. ROBINSON. *Improvements in, and applicable to, that apparatus known as Giffard's injector, and in the adaptation of it to locomotive and other boilers.* Dated January 28, 1863.

There are certain objections in Giffard's injector, and, by discoveries which the patentees have made, they are enabled to remove them—that is, they can stop the noise when working, prevent the admixture of air with the water passing through the injector, and the loss or waste of water escaping from the overflow cavity, and arrange so that the working of the apparatus can be brought more easily under the inspection of the driver or fireman in locomotive and other boilers, and, besides removing these objections, they can feed cold or hot water at the overflow cavity. Some or all of the objections are removed and the above advantages are secured by each of the improvements hereinafter described. The improvements consist in forming a cavity around and above the nozzles of the injector as a reservoir for a portion of the overflow water. The improvements also consist in applying a pipe to the overflow, so that the water therefrom will have to ascend the pipe, which is open to the atmosphere at its upper end; or the pipe is first made to ascend, and then descend, its lower end being immersed in water; or it is bent down and immersed in water. The invention also consists in connecting the overflow orifice with the suction pipe, supplying water to the injector, and placing a two-way tap between the overflow and suction pipe, so that when the communication is shut between the two, the overflow will be open directly to the atmosphere,

and when the overflow is shut to the atmosphere, it will be open to the suction pipe. The improvements in arrangements for applying the injector to locomotive and other boilers, so that its working will be better under the inspection of the driver and fireman, consist in connecting the overflow orifice with the suction pipe, and fixing a tap to open or shut the communication between them, and in joining a branch pipe to the connecting pipe, so as to ascend from it, the upper end being open to the atmosphere. *Patent completed.*

259. E. G. Muntz. *Improvements in securing axles and axle boxes.* Dated January 28, 1863.

In carrying out this invention, the patentee forms upon an axle the half section of a groove running round or partly round the axle, the counterpart of this groove being formed on the inside periphery of the box; an opening somewhat larger in diameter than the section of the entire groove is cut in the box inclining towards the groove; this opening has a flange round the orifice, reducing its diameter at that part, and forming a collar, the axle and box being fitted together with the grooves in opposition. A plug of india rubber, or other flexible material, furnished with a ring or knob at one end, below which is a projecting collar formed on the plug, is inserted in the orifice in the box, and winds itself round the groove in the axle and box, being prevented from escaping by the collar upon the plug impinging against the flange or collar formed in the opening by which it enters. The flexibility of the material of which the plug is formed allows of its being withdrawn by force when required. *Patent completed.*

260. H. Crichley. *Improvements in reaping and mowing machines.* (A communication.) Dated January 28, 1863.

This invention is not described apart from the drawings. *Patent completed.*

261. B. A. Branwich. *An improved mode of obtaining and applying motive power.* Dated January 28, 1863.

This invention relates to a novel mode of applying compressed air to the obtaining of motive power. To this end the patentee provides a chamber capable of containing the compressed air to be employed, and in connection therewith he brings a series of engines, which he proposes shall, each in turn, receive the air as it leaves the chamber, and be acted upon thereby. These several engines he proposes to connect with a common shaft, and thus to concentrate the power of all the engines. A convenient mode of carrying out this system is to construct a series of annular cases, and to fit air-tight covers thereto, but in such a manner that they will be free to rotate on their seats. To the inner face of these covers a piston is attached, which fits the case, and each case he provides with a supply and discharge pipe, between which he mounts a valve which is maintained in position by a spring or other suitable means. This valve acts as a stop to the admitted air, but will yield to the pressure of the piston, so as to allow it to pass in its rotary course. This series of rotary engines he mounts one above the other in suitable fixed framing, and sets up a vertical shaft concentric therewith. From the shaft project arms, the extremities of which are connected to the rotary covers of the engines. As, therefore, the engines are driven, they will severally exert their power in driving the common shaft, from which rotary motion may be taken off by a crank or otherwise. The engines are connected together by coupling pipes, and the top engine of the series is also connected by a supply pipe with the air chamber. The air therefore passes first to the top engine, when, having exerted its force, it goes to the next, and so on through the series, until, having operated on the piston of the last engine, it enters an elastic coiled pipe, which is connected to the air chamber. A pressing roller, driven by the central shaft, traverses this coiled pipe, and expels the air therefrom as it is supplied thereto, driving it into the chamber. Thus the same air is used again and again for driving the engines. At starting the compound engine, any available motive power may be employed for charging the air chamber with compressed air. *Patent completed.*

262. H. A. Bonneville. *Improvements in the construction of granaries.* (A communication). Dated January 29, 1863.

This invention is not described apart from the drawings. *Patent completed.*

263. J. A. Weston. *A new or improved coupling and break for transmitting, or regulating, or arresting motion.* Dated January 29, 1863.

The patentee claims a coupling and break consisting, essentially, of two series of discs, the discs of one series being incapable of rotation except with one of the two axles or other bodies to be ungeared from one another, and the discs of the other series being incapable of rotation, except with the other of the said axles or bodies; the discs of each series alternating with those of the other series, and the whole of the discs capable of a sliding motion in the line of their axles, so that they may be either separated from one another or pressed against one another, so as to produce the amount of friction which is necessary for communicating the motion of one series of discs, or for enabling one series to regulate or arrest the motion of the other series. *Patent completed.*

264. J. B. E. Louit. *Improvements in glass chimneys.* Dated January 29, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

265. J. Mackenzie. *Improvements in shaping machines for curvilinear surfaces.* Dated January 29, 1863.

This machine has the bed and frame of an ordinary planing, boring, and shaping machine, the traversing motion of the saddle and that of the bed being produced in the usual way. The cutter block is mounted upon an axle or spindle, and is either forged with it or keyed on to it, and the cutters are fixed to it in the customary manner. By means of bevel-gearing connected with the cutter block and its axle the patentee is enabled to give them an angular motion in a vertical plane, thus enabling him to shape or form curvilinear or bevel surfaces. *Patent completed.*

266. R. A. Brooman. *Improvements in the manufacture of candles.* (A communication). Dated January 29, 1863.

The objects of this invention are to obtain a brighter and more uniform light, and to prevent guttering in candles. The invention consists in the employment of a hollow or tubular wick to produce a current of air to the centre of the flame. For candles intended to be burnt in sockets or holders, which will not allow a current of air to pass through the bottom of the candle, the inventor forms an aperture or passage through the side of the candle above the socket or holder and communicating with the interior of the wick. During the manufacture of candles according to this invention he passes a spindle or rod through the wick to keep it open. *Patent completed.*

267. J. Pouncy. *Improvements in obtaining, transferring, and printing from photographic pictures or images, also in preparing materials for same.* Dated January 29, 1863.

The principal feature of this invention consists in the employment of a sensitive or sensitized ink or composition on which pictures or images may be produced by the agency of light, and which may be transferred or printed from in the manner described. *Patent completed.*

268. W. Ball and J. Wilkins. *Improvements in machinery employed in the manufacture of looped fabrics.* Dated January 29, 1863.

For the purposes of this invention, a needle bar, a presser bar, and a sinker bar are used, as in warp machines. Two guide bars are also employed, each bar having half as many guides as there are needles; these guide bars have simply a shogging or to-and-fro endway movement equal to three needles constantly communicated to them in opposite directions by lace wheels or otherwise, and the threads of these guides are constantly laid to and fro under three needles, excepting when they are intercepted by suitable interceptors, which are preferred to consist of forked rods, acted on by jacquard or other pattern surfaces. The bar which carries these forked interceptors has a shogging motion equal to the space between two needles, and there are half as many interceptors as there are needles. So long as the interceptors are not brought into action, the threads of the two guide bars are constantly shogged a distance in opposite directions equal to three needles, but when any of the interceptors are brought into action, they each receive in their forked ends two of the guides, and prevent them shogging to the full extent of their otherwise constant action. A third guide bar is also used, the threads of which are caused to lap on to the needles, and to be looped thereby, so as to form as many looped pillars as there are needles. The guides of this guide bar are cranked towards the needles, and there are as many upright points with eyes or holes through them near their upper ends as there are needles, so that the threads pass through such holes or eyes in the upright points, and then through the holes or points in the guides. The guides and points of this third guide bar rise up through the threads of the other guides, and are then caused to be shogged, so as to lay their threads on the stems of the needles; but before this rising of the guides and points and the lapping of the threads on to the needles takes place, points on a suitable point bar are caused to come forward, and to draw the threads which have been traversed under the needles in towards the work, so that when the threads of the guides of the third guide bar come up, they shut the traversed threads into the fabric. The threads which lap over the needles are by the working of the machine caused to be moved under the beards of the needles, and the work is knocked over the heads or ends of the needles by the needle bar being caused to move back, the heads of the needles being closed by the needle bar, as is well understood. *Patent abandoned.*

269. J. Nadal. *Improvements in fountains.* Dated January 29, 1863.

This invention has for its object improvements in fountains. For these purposes, an upper and a lower vessel are employed, which are combined together by a suitable stem or pillar. It is preferred that the upper vessel should be in the form of a basin, while the lower vessel should be in the form of a base, and that they should be combined by a stem or pillar; but other devices or forms of vessels may be employed. The upper and lower vessels are both closed. In the upper part of the upper vessel is a jet pipe, which descends to nearly the bottom of such upper vessel. There is also another pipe descending from the upper part of the upper vessel down through such vessel, through the stem or pillar, and down into and nearly to the bottom of the lower vessel. This pipe may be called the supply pipe, as it is by this pipe that water or other fluid is supplied to the lower vessel, and by which also the water or other fluid coming from the jet or jets descends into the lower vessel. The upper vessel is supplied with water or other fluid by removing the jet pipe. In addition to the above-mentioned pipes, there is also another pipe which, by its lower end, is fastened to the top of the lower vessel, and it ascends through the upper vessel nearly to the top. By these means, supposing the upper vessel to have been filled with water or other fluid, on pouring a quantity of water or other fluid into the supply pipe, such water will press on and displace the air in the lower vessel, and cause it to ascend into the upper part of the upper vessel, and thus cause the water or other fluid therein to be driven through the jet pipe, and a continuous action will take place so long as there is any air to be driven into the upper vessel. *Patent abandoned.*

270. N. Clayton and J. Shuttleworth. *Improvements in thrashing machines.* Dated January 29, 1862.

According to this invention, the grooves or channels are formed parallel to each other longitudinally along the face of each beater, not, however, in straight lines as heretofore, but in serpentine lines. It is preferred that each beater of the drum of a thrashing machine should be formed with three serpentine grooves; this number is not, however, essential, as the number of the grooves or channels in the face of a beater may be varied. The whole of the grooves or channels, although they are parallel to each other, and formed in a longitudinal direction along a beater, do not in consequence of a beater having parallel sides all pass from end to end of a beater, but only some of them, whilst others only extend along a comparatively short length of a beater. *Patent completed.*

271. C. H. G. Wilbany. *Improvements in the manufacture of red colouring matter.* Dated January 29, 1863.

In order to produce a red colouring matter suitable for dyeing and printing, the patentee heats two equivalents of aniline, or its homologues, and one equivalent of phosphate or acetate of mercury. It is preferred that the aniline or its homologues should be in combination with acetic acid, as acetate of aniline (or of a homologue thereof); or it may be combined with hydrochloric acid, nitric or sulphuric acid, as a hydrochlorate, nitrate, or sulphate; or the aniline or its homologues may be employed in an uncombined state, or partly in the state of a salt and partly in an uncombined state. *Patent completed.*

272. A. Pritchard. *An improved method of preserving the contents of packages from air, water, or damp.* Dated January 29, 1863.

The materials to be packed are first to be made up into packages or packets of any convenient form and size, the coverings or outsides whereof may be of paper, chip, wood, or any other suitable material, which packages or packets are to be dipped or immersed in a boiling composition (which the patentee terms alkareen or alkarene) composed of asphaltum, coal tar, or coal pitch and soft pine pitch boiled together, which composition when applied forms a hard glossy enamel on the surface of the packets capable of resisting alkalies, air, water, or damp. *Patent completed.*

273. G. Blake. *Improvements in heating aparatus for heating and warming.* Dated January 29, 1863.

This invention relates to the construction of stoves of corrugated or waved or zigzaged iron (or other suitable metal) or fire-clay. A fire placed inside the improved stove is the usual source of heat; but steam, hot water, or a gas flame are applicable. In the first place, the patentee prefers to use plain sheets of iron to form the case, to which the corrugated iron or material is fastened by means of rivets, bolts, or otherwise, such corrugated iron or material deriving its heat through the case of the stove, partly by radiation, and partly by conduction: but these stoves may be constructed without such cases of plain sheets of iron when the corrugated iron or material forms the case, deriving its heat directly from the fire or furnace. In this form the corrugated stove may be constructed of fire clay (burnt in the usual way), or of cast iron or wrought iron. *Patent completed.*

274. W. Clark. *Improvements in the condensation of steam and in apparatus for the same.* (A communication.) Dated January 29, 1863.

This invention is based on the following principles:—1, To project the water on the outside of the surfaces in contact with the steam to be condensed, instead of injecting the water into the condenser, and mixing it with the steam. By rapidly renewing the water thus obtained, the inventor remedies the defective conductibility of the water; hence, he requires apparatus of but small dimensions compared with those ordinarily used. 2, The condensing surfaces are disposed in the form of a diaphragm in any suitable manner, but the essential feature of that which is here expressed by the word diaphragm is, to present surfaces accessible on both faces by simply opening a port or removing a cover, and this arrangement, which constitutes the fundamental principles of the system, permits of cleaning the surfaces with ease, even when in motion; it has also the further advantage of allowing free expansion, and preventing all escapes. 3, The distilled water is separated from the fatty matters employed in lubricating the different parts of the machinery, so as to furnish the waters perfectly pure to the boilers. 4, To restore to the distilled water passing from the condenser to the boiler, and from the boiler to the condenser, any quantity which may escape, without any increased attention on the part of the driver or stoker. *Patent completed.*

275. J. Sainty. *Improvements in feeding troughs for sheep and other cattle.* Dated January 29, 1863.

According to this invention, the inventor makes the body of the trough of galvanized sheet iron, which he bends of a cylindrical form, but uses only a section thereof, unbracing rather more than half the circumference. This body he mounts between two cast-iron ends having suitable grooves or projections to receive the ends of the body; these ends are connected by stretcher bolts which connect the whole firmly together. He disposes one stretcher below the bottom of the trough, while the other two pass through heads turned on the edges of the trough, which thereby form round lips or edges thereto; suitable feet are rivetted on to the ends to raise the trough from the ground. By forming the trough of rather more than half a cylinder, the upper parts or edges are turned inwards, which prevents the sheep or other cattle from dispersing the food over the edges, and also prevents the wind blowing it out. Stays are placed across the mouth which serve for hand holds, and also to prevent the cattle dispersing the food and throwing it out; the ends of these stays pass through just below the beaded edges, over which they are turned and bind the sheet iron on the stays. *Patent abandoned.*

276. F. G. Stuber. *Improvements in the construction of air-tight boxes, cases, cupboards, and similar vessels.* Dated January 29, 1863.

This invention consists in the construction of air-tight boxes, cases, cupboards, and similar vessels, in which valuable materials may be preserved from damage by water or moisture, and perishable substances have their decay retarded or arrested by being surrounded by an atmosphere different in condition or nature from the ordinary atmosphere. These vessels are not to be assumed air-tight, but proved to be so, and a test tube or collar is placed somewhere in the vessel for connecting apparatus to the vessel for doing so. The vessels are constructed of metal, or woo

and metal, and vulcanized india-rubber, or other elastic material, which should be vapour-tight, is interposed between the door or lid of the vessel and the vessel itself. Some or all of the fastenings should be modified so as to be readjustable without removal, and to give the necessary pressure upon the lid without adding to the weight. *Patent completed.*

277. J. W. BRANFORD. *The purposes of hoeing and cleaning the land, and for cutting and setting out the plants of lost crops at certain distances from each other, and which invention he designates a longitudinal and transverse hoe.* Dated January 30, 1863.

This invention consists of an implement with two travelling wheels, to be drawn by one horse, having a bar affixed to the frame, upon which are placed four hoes for cutting the ground longitudinally; also an iron shaft with two driving wheels turning two pinions with shafts, to which are attached two iron plates with four knives or hoes on each for cutting or setting out the plants, working in a transverse direction. There are levers for striking the gear and lifting the hoes out of work, and also the travelling wheels, and a pair of shafts to which the horse is harnessed for drawing the implement. *Patent abandoned.*

278. W. E. GEDGE. *Improved apparatus for cleaning chimneys and other flues.* (A communication.) Dated January 30, 1863.

This apparatus is composed of a given number of iron rods fitted at their lower ends in a block of wood; these rods have small scrapers on their tops. On opening out the assemblage of rods or wires (which is effected in the chimney fan-wise but circular) these scrapers perform their office on the inside of the chimney. When not in action they are enclosed within four pieces of wood, surmounted by a hinged platform with wheels. By means of a rod which slides in the supports of the platform—and to which supports are attached four chains, the ends of which are united on the top of the said rod, and a chain passing downwards from the bottom of the rod—the apparatus is opened out when required. *Patent abandoned.*

279. W. E. GEDGE. *Improvements in cones or forms for moulding refined sugar.* (A communication.) Dated January 30, 1863.

Instead of making the cones or forms for moulding refined sugar in the ordinary manner, the cone, the subject of this invention is made of a single piece of sheet iron, of which the edges are tapered or thinned down so as to present, on the outside, as little ridge or waviness as possible. The interior of the cone is perfectly smooth, and the two edges of the iron are first adjusted by small rivets, the heads of which are filed or otherwise smoothed down; then the joint is soldered or brazed with the usual brass and zinc soldering. *Patent abandoned.*

280. J. COCKER. *An improved turnstile, especially applicable to omnibuses and other vehicles to show or indicate the number of passengers that have been carried.* Dated January 30, 1863.

We cannot here give space to the details of this invention. *Patent abandoned.*

281. N. P. O. LLOYD. *Engines of any desirable power to be worked without the aid of steam, heat, or any auxiliary other than atmospheric pressure.* Dated January 30, 1863.

This invention is carried into effect as follows:—A metallic tube or cylinder is to be inserted at a right angle into a square or otherwise-formed metallic plate, and a metallic rod or bar is to be inserted at a right angle into a corresponding plate, and these plates are to be united by means of a hinge which will permit them closely to approximate or to separate at a necessary distance. The sides attached to these plates will, when the plates are separate, be air-tight by means of appliances connected with the sides and similar substances above and below them. This apparatus may be termed No. 1. Another apparatus similarly constructed and termed No. 2, will be used. The tube of No. 1 and the rod or bar of No. 2 will pass through apertures provided with air-tight substances, in one side of a cubic or elongated metallic air-tight box or chamber, from which air will, through a stop-cock by means of an air-pump, be extracted. The bar of No. 1 and the tube of No. 2 will pass through apertures provided with air-tight substances in corresponding parts of the opposite side of the chamber; a stop-cock connected with the tube of No. 1 being opened will admit air between the metallic plates. The air will force No. 2 (being connected with No. 1 at the air-tight receiver) through the chamber, and will raise No. 1 to the position it occupied while quiescent, and cause the rod of No. 2 to pass without the chamber. The air in No. 2 will, by means similar to those provided for No. 1, be removed into a similarly placed receiver. The air that passed into the receiver of No. 1 will, by means of a hinge, cause the plates closely to approximate and remove the air between the plates into the receiver whence it was obtained; hence, air admitted alternately into each receiver, will move the united apparatus 1 and 2 in alternate opposite directions. Two tubes and two bars being alternately forced within and without the chamber, and being connected with the right and left wheels of the engine and the first carriage or other machinery, will act with double power. *Patent abandoned.*

282. W. E. NEWTON. *Improvements in couplings for railway carriages.* (A communication.) Dated January 30, 1863.

The object of this invention is effected by the employment of spring catches placed within the coupling boxes, and which catches, retain, and hold back the draw-rod or box, which is provided at each end within an inclined projecting piece, so that, when the end of the rod is inserted, it will lift up the spring catch and pass under. These spring catches work in vertical grooves, and the stem of the catch passes through the top of the box, and is provided with a ring or hook, whereby the catch may be drawn up when it is to release the draw bar. Swells or protuberances are made on the sides of the draw bar near its ends, so that, should the carriage be thrown off the rails, the angle that the draw bar will then be made to deviate from a straight line will cause the swells or protuberances to lift up the catch and release the bar. The rear of the coupling box is provided with a rod which passes into another box and acts on a draw spring made of vulcanized india rubber, which may be compressed in either direction, that is whether the carriage be driven forward or pushed backward. *Patent completed.*

283. W. E. GEDGE. *Improvements in hair nets.* (A communication.) Dated January 30, 1863.

This invention consists in the use of human or animal hair exclusively in the manufacture of nets intended to hold or secure in position a lady's hair or coiffure. As regards their manufacture, it is only necessary to observe that the network is best made with the hairs two and two spade-headed, "tête bêche," twisted together, and when the net is completely made, it should be vaporized on a suitable vaporizer to give it finish and fix the knot. *Patent completed.*

284. M. SMITH. *Certain improvements in looms for weaving.* Dated January 31, 1863.

This invention consists—1, in the application of two chains of tappets working on the same barrel, or placed at the same side of the loom for working by a cross shaft, and the usual levers and rods, and the drop boxes at both sides of the loom. 2, in working the jacquard and the vibrator by the same lever, actuated by the second motion wheel or other convenient part of the loom. 3, in making the lower edge of the vibrator in line with the axis on which it vibrates, for the purpose of maintaining a uniform action on the warp, irrespective of the diameter of the warp beam. 4, in supporting the shaft for working the jacquard barrel in a lever, the fulcrum of which coincides with the pitch line of the wheels by which the barrel is driven, so as to be able to throw the barrel beyond reach of the needles, whereby the cards are kept in order and position when the loom is turned back; or the same object is accomplished when the jacquard is placed below by a pinion on the crank shaft driving a pinion on a side shaft, on which is a cam or scroll acting on a fixed pin. 5, in making the jacquard barrel with two or more rows of holes, and varying the level of the needles by a cam shaft or other equivalent, so as to bring them in line with any required row of holes. 6, in giving a positive motion to the taking-up roller by wheels and pinions driven by the crank or tappet shaft, and dispensing with the ratchet wheel now generally employed. By this means when the loom is turned back a similar motion is given to the taking-up roller. 7, in an improved weft stop motion, consisting of a thin blade of steel or other metal fitting between the dents of the reed, and sliding in brackets attached to the hard top and batten. This blade is raised at every pick by an incline attached to the breast beam or other convenient fixture, and in dropping between the warp threads which form the grid it feels for the weft; if the weft is absent the blade drops and acts on a lever connected to the stop rod for the purpose of stopping the loom. *Patent abandoned.*

285. J. LIGHTFOOT and F. TRACHSEL. *Improvements in the distillation of certain substances, and in apparatus employed therein.* Dated January 31, 1863.

This invention relates to a system of continuous distillation which is performed by this improved still, the construction of which is as follows:—The inventors take a strong tube, made of any suitable metal or material, and any convenient form or shape, which is provided with a main tap or valve at one extremity to admit and regulate the flow of steam within the tube; at its other extremity it is provided with a tap or valve to let out the condensed water and the surplus steam. This tube is placed in a slanting position, and they rivet, solder, or braze at the upper surface of the tube longitudinal slips of metal forming a trough or channel, and also sometimes transverse ridges or small bars, either metallic, glass, porcelain, or other suitable material, to increase the surface and retard the flow of the liquors passing upon them. The tube thus prepared is enclosed in a larger one, made of similar materials to the first; both ends of this outer tube or case are closed, and in order to let off the vapours of the substances distilled, they adapt at or near to the extremity of this outer tube a head or bent tube, similar to a swan's neck, which is joined or connected with proper worms, coolers, or condensers. At the upper end of the outer case they also place a smaller tube to deliver a stream or streams, jet or jets, or droppings of the matters undergoing distillation by the heat of the inner steam pipe. This smaller tube has a proper tap or valve to regulate the flow of these matters from the supplying vessel. At the lower extremity of the outer case they also place an outlet to pass off those matters which have undergone the operation of distilling, and which are left as residues. This outlet pipe may be put in communication with a worm or cooler, or may pass at once into a waste still or other convenient vessel. *Patent abandoned.*

286. T. BENNETT. *Improved arrangements for obtaining pictorial backgrounds, foregrounds, and perspectives, when taking photographic portraits or sun pictures.* Dated January 31, 1863.

In taking photographic portraits or pictures in which it is desired to adopt suitable backgrounds, foregrounds, or perspectives, it has been hitherto the practice to use a painted canvas descending to and terminating at the floor or standing-place of the apartment or place. Now, according to this invention, the patentee uses a canvas (or equivalent substance) suspended or secured upon a roller or rollers with pulleys and cords, by which the canvas can be raised or lowered. The said canvas (or its equivalent) is always of sufficient length to allow it to be brought down to the floor, then stretched along the same, and kept in position (if desired) by catches or grippers, so that the person or persons, or principal object or objects to be portrayed, may stand upon a part of the canvas or equivalent. The background, foreground, or perspective, which is to remain perpendicular, or nearly so, is to be painted or depicted in the ordinary or perspective manner, and that part of the canvas or equivalent which is to lay upon the floor is to be painted so as to have the same convenient effect as the upright part, and so as imperceptibly to "run into" the same; for which purpose he has hitherto adopted the plan of first painting the upright part and fitting the same to a corresponding position to that in which the same is intended to be used, and then stretching the horizontal part upon the floor, drawing lines or objects by the aid of camera. *Patent completed.*

287. J. GROSSMITH. *An improved mode of producing the aura-electric gas.* Dated January 31, 1863.

In the production of the aura-electric gas, the inventor claims the application of a new radiator by acting upon a solid, and the use of a radiating multiplied network forming shelves, by which he presents more surface for the air to act upon the volatile liquid than hitherto. He uses multiplied wire network for every one of the shelves, by which he presents both top and bottom surfaces for radiation. He claims the use of asbestos as the diffuser of the volatile liquid, by which he again presents surface at all angles of his cylinder. *Patent abandoned.*

288. F. TOLHAUSEN. *New or improved apparatus for cleaning the beams of mules and spinning frames, collecting the dust and waste thereof, and also for clearing the flooring.* Dated January 31, 1863.

The first part of this invention relates to a self-acting apparatus for cleaning the rollers, and also part of the rollers and beams of mules, self-actors, and other spinning frames. This object is accomplished by means of a brush, or block set with brushes or pencils standing out at different angles, so as to sweep the different parts to be cleaned. This brush is made to slide to and fro in a suitable guiding tube in front of and near the roller beam, and is set in motion from the front line of drawing rollers by means of double bevel-gear, drums, and endless mule banding. The reversing motion is obtained by a worm and wheel acting on catches and springs that actuate a lever, by which one or the other of the opposite followers of the bevel-gear is thrown into gear with the driving. The second part relates to collecting the wash delivered by the brush, and also wiping the top of the mule carriage when it runs in near the roller beam. This contrivance consists of a cloth of woolly texture, which is hung loosely under and near the roller beams, so as to receive the waste swept off by the self-acting brushes. The under or bulging side of this cloth also wipes the top of the mule carriage when it draws up under it. The third part of the invention relates to an apparatus for cleaning or dusting the flooring under the spinning frame, and which is traversed over by the carriage. This apparatus consists of a shaft mounted in suitable bearings in the mule carriage, and carrying by means of arms a rotary cleaning roller covered with flannel or other suitable material. This roller is let down so as to roll on the floor, and gather the waste thereon whilst the carriage is running out; and, when the carriage begins running in, the said roller is lifted off the floor, which is effected in a self-acting manner by means of stops and catches, and a click and ratchet motion lifting and holding up and releasing or lowering the roller arms at each end of the carriage path respectively, thus producing the desired effect. *Patent completed.*

289. W. DRUMMOND. *Improvements in apparatus for stopping the supply of gas to burners when the light is put out.* Dated January 31, 1863.

For the purposes of this invention a continued supply of gas is made to depend on the heat of the burner, or of part of the apparatus by which the supply of gas is governed, and such heat is caused to act on the valve of the instrument by which the supply of gas is allowed or prevented by means of expanding air, or it may be gas confined within a suitable chamber or space contiguous to the burner; or like arrangements may be made on the supply pipe contiguous to the main or on in any convenient position. It is preferred in all cases to employ an inverted cup or hollow vessel with its inverted edges dipping in quicksilver, so as to enclose a quantity of air, so that when the gas flowing through a burner has been lighted for a short time and the air expanded, the inverted vessel will be raised, and by its being raised will keep open the supply passage leading to the burner; but should the lighted gas be put out, the cooling of the air will allow the inverted vessel to descend, and thus close or be the cause of closing the supply passage. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated July 31, 1863.

1894. J. C. Haddan, of Bessborough-gardens, Pimlico, civil engineer. Improvements in firearms, and in artillery and projectiles for the same.

Dated August 6, 1863.

1938. J. G. Pinède, Liancourt, Oise, France. Improvements in apparatus for regulating the speed of steam and hydraulic engines.

1947. T. Simmelkiar, Black Rock, Cork, and J. I. Spicer, Park-road, Old Ford. An improved composition for coating or painting the bottoms of ships or vessels to prevent them from fouling.

Dated August 10, 1863.

1968. P. M. del Rio, Jermyn-street, St. James's, gentleman. A new machine for obtaining motive power.

Dated August 13, 1863.

2000. J. Edmunds, Birmingham, gunmaker. An improvement or improvements in gun and pistol furniture.

2004. M. A. F. Mennons, Abingdon Chambers, Westminster. Improvements in the construction of numbering machines. (A communication.)

2006. H. Brown, King-street, Cheapside, gentleman. Improvements in burners for lamps for burning oils or fluids.

Dated August 14, 1863.

2010. R. B. Greenwood, 416, Hackney-road. Improved means of preventing accidents upon railways.

2012. E. B. Wilson, 5, Parliament-street, Westminster, engineer. Improvements in blast furnaces.

2016. N. S. Russell, Great George-street, Westminster, civil engineer. Improvements in apparatus for working great guns.

2018. W. Asbury, Birmingham, engineer. Improvements in axles and axle boxes, and the parts of wheels immediately connected therewith.

Dated August 15, 1863.

2022. G. Davies, 1, Serle-street, Lincoln's-inn, civil engineer. Improvements in furnaces for heating, flattening, and annealing glass. (A communication.)

2024. R. Parker, Atherton, Lancaster, spindle and fly maker. Certain improvements in presser flyers to be employed in preparing, spinning, and doubling cotton and other fibrous materials.

2026. E. Lord, Todmorden, Yorkshire, machine maker. Certain improvements in machinery for preparing, spinning, and doubling cotton and other fibrous substances.

2028. J. E. F. Ludeke, 2, Elizabeth-terrace, Islington. Improvements in the means of keeping cameras or other apparatus steady when suspended to balloons.

2032. R. Lightbown, Over Darwen, Lancashire, manager. Improvements in looms for weaving.

2034. G. T. Bousfield, Loughborough Park, Brixton. Improvements in the manufacture of cement. (A communication.)

Dated August 17, 1863.

2036. J. Smith, Cheetham, Manchester, bleacher, dyer, and finisher. Improvements in machinery for finishing woven fabrics.

3040. W. Longbottom, Nelson Foundry, Barnsley, Yorkshire, machinist. An improved lubricator.

Dated August 18, 1863.

2046. J. Briggs, Blakely, Lancashire, engraver to calico printers. Certain improvements in coating or covering crinoline steel.

2048. H. Robinson, Skipton, Yorkshire. Improvements in lime kilns.

2052. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the manufacture of hats, caps, and bonnets, and in apparatus connected therein. (A communication.)

2054. J. B. V. Faure. Improvements in pen and ink holders.

Dated August 19, 1863.

2058. C. Sonnhammer, Regent-street. An improved fan.

2060. T. Scott, Nelson-square, Surrey, engineer. Improvements in the construction of floating docks or apparatus for lifting ships and other bodies.

2062. S. Sanderson, High-street, Shoreditch, merchant. An improved fastening for leggings, stays, or other articles.

2064. R. H. Jackson, Olive Branch Works, Meadow-lane, Leeds, tool maker and machinist. Improvements in machinery for sawing wood and other fibrous substances.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, September 1, 1863.

966. J. Goucher. Steam boilers.

967. R. C. Clapham. Treating the waste liquors from bleaching powder stills in order to obtain hydrochloric cid and other products therefrom.

986. H. Rafter. Printing surfaces.

988. E. L. Simpson. Waterproof compounds.

991. J. W. Nottingham. Two-wheeled vehicles.

993. H. Donald. Bending or straightening metal plates.

996. W. Campion and G. Wilson. Machinery or apparatus employed in the manufacture of looped fabrics.

1005. J. Lee and E. Dawson. Looms for weaving.

1014. J. Cavanah. Cricket bats.

1016. W. N. Wilson and J. G. Grey. Machinery for sewing and stitching.

1028. C. Pooley. Certain parts of machinery for preparing and spinning cotton and other fibrous substances.

1034. J. Dunbar, jun., and J. W. Woodford. Apparatus for steering and manœuvring ships and vessels.

1036. A. Poirrier and C. Chappal. Blue and violet colouring matters, suitable for dyeing and printing.

1038. C. Beyer. Safety valves. (A communication.)

1039. I. Dimock. Machinery for cleaning, sorting according to size, and doubling silk and other threads.

1042. W. E. Newton. Thrashing machines. (A communication.)

1050. M. Valkenhuysen. A new castor for furniture.

1072. G. E. Donisthorpe. Apparatus used when getting coal and other minerals.

1085. H. W. Ripley. Apparatus for printing fibrous materials. (A communication.)

1086. M. Henry. Apparatus for manufacturing beton and artificial stone. (A communication.)

1092. C. P. Stewart and J. Kershaw. Engines, machinery, and apparatus for obtaining compressed air, and for applying the power thereof in propelling railway and other carriages.

1113. G. Haseltine. Springs for railway carriages and other purposes. (A communication.)

1124. W. Glover. Steering of ships and other vessels.

1130. S. Hibbert, J. Lawton, and J. Kay. Cleansing potatoes, and in decorticating the same and other esculent roots.

1133. G. Davies. Forging and dressing horse-shoe and other nails. (A communication.)

1146. C. A. Day, A. Lamb, and T. Summers. Marine engines.

1179. C. and W. Shorrock. Power looms for weaving.

1204. V. J. Cassaignes. Stereoscopes.

1239. J. Whitehead. Motive-power machinery.

1281. R. A. Brooman. Breech-loading ordnance and breech-loading and other small arms. (A communication.)

1425. W. E. Newton. Nozzles for hose and water discharge pipes. (A communication.)

1613. R. Mushet. Manufacture of iron and steel.

1760. J. Davison. Furnaces for boilers, smelting, and other useful purposes.

1778. H. Mége. Mode of treating fatty bodies.

1845. W. and J. Garforth. Preparing, beetling, or finishing textile fabrics, such as cotton, wool, linen, or other fibrous materials.

-2. S. Bury. Valves for steam engines.

1980. A. V. Newton. Process for hardening cast iron. (A communication.)

1986. G. Graham. Baths or boilers used in dyeing.

1987. R. Mushet. Cast steel.

1988. J. Cornforth and A. Andrews. Nails commonly called screw-rivets.

2034. G. T. Bousfield. Manufacture of cement. (A communication.)

2046. J. Briggs. Coating or covering crinoline steel.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LOCOMOTIVE CONSTRUCTION.

NOTWITHSTANDING the dictum contained in Clark's "Railway Machinery," we cannot regard the link motion as otherwise than imperfect. Its comparative excellence we admit; but with the growing tendency for higher pressures and early cut-off, its defects become day by day more prominent. In order to maintain anything like a full pressure on a piston, moving at 800 or 1,000 ft. per minute—a speed frequently reached in express engines—it is essential that all passages leading to the cylinder should not only be short, direct, and of large area, but that they should be opened and closed with a velocity proportionate to the speed of the piston. Locomotives are seldom worked in the central notches, except when running fast. The travel of the valve is then shortened, and the ports not only reduced in area, but opened and closed with a tardiness, which greatly militates against the advantage to be derived from an early cut-off, diagrams taken at high speed showing a very remarkable loss of pressure as the piston pursues its course through the cylinder. Steam is estimated to flow into a vacuum with a velocity equal to that due to a body of the same density, falling through a space equal to the height of a column of steam of the given pressure. By this rule, steam of 120 lb. pressure would flow into a vacuum at about 2,079 ft. per second; but the difference between the velocities of any two pressures, is the velocity with which steam would flow into steam of a lower pressure. At the commencement of a stroke, or rather at the moment when the valve first opens, the pressure within the cylinder is comparatively trifling, steam then enters with great velocity; once, however, the difference in the densities of the steam in the boiler and that in cylinders ceases to be well defined, steam passes very sluggishly from the former to the latter, and is little able to overcome the resistance offered by long curved passages and the contracted areas of the steam ports. It is very unusual, in consequence, to maintain more than 70lb. in the cylinder at high speed, indicator diagrams falling at once on the commencement of the stroke, long before steam is really cut off. The analyzation of such diagrams is not easy, as it is impossible to tell, without setting out and measuring the valve gear, when the valve really closed. Theoretically, the ports should be extremely short, straight passages, opening directly from the valve-seat into the cylinder. The great size of the valve required to suit such an arrangement has hitherto precluded its adoption. Mr. Clark gives us good reason to believe that as much as 25-horse power is frequently expended in working valves as it is—a positive waste of power which it would be very injudicious to add to. If, however, the valves are properly balanced, there is nothing to prevent the employment of any size deemed most desirable; and if we are to adhere to the link and eccentrics, the sooner we have a large valve with a long throw, and great lap, the better. We illustrate this week a form of balance-valve, which, although recently patented here, has been worked for some time in America with considerable success. Plainmaison's slide-valves have been adopted on the Chemin de Fer du Nord since the year 1861 with excellent results, both in the Crampton express and Engerth goods engines. Railway companies don't like change, however; and the general introduction of the balance-valve is, here at least, apparently as far off as ever.

Quitting the subject of valves, and resuming the consideration of the means by which they are put in motion, we find existing arrangement, lauded for a simplicity which they do not really possess. The link motion, consisting as it does of two eccentrics with their rods, straps, pins, &c.; a link often built up of many pieces; and a rocking-shaft with balance weights or springs; is really the most complex part of the engine. Its expense is very considerable at first; and from the rapid wear to which it is exposed, and the nice adjustment which it must preserve, its maintenance forms a large item in the working expenses of the locomotive. We are well aware that this must be a distinguishing characteristic of any valve gear whatever; but we believe that other arrangements not a whit more complicated, will give better results. The mere fact of such a piece of machinery, delicate and finely wrought, answering its purpose so well, should rather encourage us in searching for a substitute which, not more simple, perhaps, would regulate the admission of steam to and its exit from the cylinders after a fashion approaching more nearly to theoretical excellence. Complexity is in itself no evidence of erroneous design. It only becomes reprehensible when it is introduced unnecessarily. In the construction of machinery, the end usually sanctifies the means; and there is no reason that a valve gear may not be very excellent, and very complex as well. In America, the use of the separate cut-off was long adhered to, and is even still held in high favour by many builders. At least one locomotive in the great Exhibition last year was so fitted, and it seems likely enough that its general adoption is not far distant. The variation in the lead, when the reversing lever is in different notches, is not the least objection to the link motion. The setting of valves is in consequence a positive science, and one understood or at least practised, only recently. A few years ago it was quite exceptional to meet with a locomotive which "beat" equally. Even yet there is great room for improvement on most of our great railway lines.

The question of balance weights, at one time considered definitively settled, seems likely to be re-opened. It is extremely doubtful that it is good practice to perfectly balance the reciprocating parts of a locomotive. One locomotive superintendent has removed three-eighths of the accurate counterpoise from his engines, with manifest advantage. The solution of the problem lies, we fancy, in the fact that the pressure on the piston does not accurately represent that on the crank-pin, when the engine is in motion, because it is modified more or less by the momentum of the piston, rod, and connecting rod—to such an extent, indeed, in some cases, that the strain on the crank-pin is much greater near the termination of a stroke than at its commencement, although the steam is early cut off. As the equilization of the impelling force on the crank-pin is extremely desirable, tending as it does to the steadiness of the entire machine, it is not improbable that a heavy cross-head, piston, and piston-rod may be better for high-speed locomotives cutting off very early, than those of a lighter construction. There can be no doubt, however, that the wheels must be accurately balanced, and this rule is seldom or never disputed. In conducting experiments on the subject, care must be taken to distinguish between the conditions under which an engine is tried in the shed, and those under which it performs its work on the road.

There is little tendency to alter the practice which deems a single pair of drivers sufficient for express engines. Locomotives intended for high speeds seldom or never are burdened with heavy trains, and with rails in good order they manage to proceed well enough, but, unfortunately, not without doing great mischief to the permanent way, in consequence of the excessive loads placed on the drivers to secure adhesion. Still there seems to be much weight in the arguments which are urged against coupling wheels over 7 ft. in diameter, which make 270 revolutions betimes in the minute. The momentum of an 8-ft. side-rod at such a pace would be something tremendous, and its fracture would lead to fearful results. For ordinary passenger trains there is no excuse for limiting the number of drivers to two; and coupled engines are rapidly getting into favour for this kind of work. For æsthetical as well as mechanical reasons, the second pair of driving-wheels should be placed behind the fire-box, not forward. If inside cylinders are adopted, the latter position throws all the work out of the horizontal line, and entails many difficulties with the smoke-box and framing. A few large engines of this class are doing good service on the North-Western, between Birmingham and Stafford. The driving-wheels are, we believe, 6 ft. in diameter, and hence the cylinders do not come inconveniently near the ground.

Steel tyres make their way rapidly into favour with locomotive superintendents, while the civil engineer regards them with unmitigated disgust, from their destructive effect on permanent way. Six or seven tons on a single wheel was, however, more than any iron tyre, possessing toughness enough to be safe, could bear without spreading; and to the employment of the hard irons which were resorted to as a remedy, may be attributed many of the accidents once so prevalent from the fracture of tyres. Railway companies have found it much to their advantage to purchase rails honestly made of good iron properly worked, instead of cheaper brands which proved utterly worthless. Steel tyres are not very injurious to such rails; still, a softer material is better for adhesion, cheaper to work, and perhaps safer, in some respects, than steel. If a tyre could be made one, with the wheel rim proper, there is no doubt that its durability would be considerably increased; not only would its resistance to spreading be greater, but the shocks and vibrations to which it is exposed would be transmitted to the entire mass of the wheel, instead of being more or less retained in the tyre. Under the present system, the tyre is exposed to a treatment nearly similar to that which it received in the rolling mill which gave it existence, the interior being nearly as much injured by the wheel rim, as the exterior is by the rail. Mr. G. S. Griggs, of the Boston and Providence Railroad, U.S., many years ago, set all his tyres on wood to avoid this action. The rims of the wheels are made with dovetailed recesses all round, running in the direction of the axle. Into these recesses hard wood-blocks, thoroughly dried, are firmly fixed, with the grain running in the direction of the groove. The tyres are then shrunk on, resting wholly on the wood, which stands, say, an eighth of an inch or less above the surface of the wheel rim. Mr. B. Adams has brought out a far more elegant arrangement here. He introduces a continuous hoop spring, fitting within an internal groove in the tyre, between it and the wheel. Two of these

hoops are, we believe, employed at present, each about one-third of an inch thick and 3½ in. wide. The wheel rim is turned slightly convex, and rests on the hoops, which of course surround it. Experiments conducted on the St. Helen's Railway, Lancashire, show that Staffordshire tyres, fitted to wheels on this system, have given first-rate results when put in competition with Krupp's steel, Swedish, and Hood and Cooper's best iron, fitted in the common way. Krupp's tyres have run 40,873 miles, Hood and Cooper's 20,798, Swedish 34,006, without requiring turning up, as an average mileage; while Staffordshire tyres, fitted on springs, have run 55,138 miles, remaining in excellent condition. The engines had all 4 ft. 6 in. wheels, except the last, which had 4 ft., and their weights varied from 19 tons 15 cwt. on Krupp's, to 20 tons 6 cwt. on Hood and Cooper's, 23 tons 14 cwt. on Swedish, and 21 tons on Mr. Adams' tyres. The saving to the rails must be considerable, for tyres can only be worn out at the expense of the rails. This same question of tyres nearly concerns the prosperity of railway companies. The maintenance of the permanent way is one of the heaviest items of expenditure which they have to encounter; and as the destroying element is found in the wheels of the locomotive, every improvement of which they are susceptible should be applied to them, without regard to the primary outlay, which is certain to repay itself a hundredfold.

THE VENTILATION OF ENGINE ROOMS.

The efficiency of the marine engine depends so much on the physical powers of the firemen, that it is rather singular that so little attention is paid to the means of rendering their toil endurable. In the factory or the mine, the supply of fresh air and a regulated temperature to the hands employed, is justly regarded as a matter of extreme importance; employers well knowing that money laid out to secure these desiderata, is always expended to advantage. The health of the operative is, according to recognized laws, well understood to tend powerfully to the master's prosperity. No man can work to advantage in a situation too hot or too cold; while a vitiated atmosphere goes a long way towards making the best hand worthless. Much, it is true, still remains to be done, through the length and breadth of the land, to enable our working population to participate in the benefits which some science and a little money, judiciously laid out, would enable them to enjoy. Still our workshops, as a rule, are roomy, and, in common with our mines, well ventilated; cool in summer and warm in winter. The moment we leave the land, however, we find in our steamships a marked exception to all this in stokeholes and engine-rooms so intensely heated, that it seems marvellous that man can endure such a temperature. Fresh air there is in plenty—the supply of the furnaces demands that; but the mere fact of a stokehole receiving ten or twelve thousand cubic feet of air per minute, is no argument that the temperature within it is not excessive, or that from such a cause alone it will or can be kept within reasonable limits. It is unfortunate that little or no attention has been devoted to a subject which is of considerable importance, not only as regards the health and comfort of bodies of men, who now really form the great bulk of the crews of our sea-going ships, but the durability and safety from fire of wooden vessels as well. Even in iron ships dangerous fires have ere now broken out from the intense heat of the boiler-rooms communicating either with inflammable cargo carelessly stowed, or with wooden decks improperly fitted. That the subject is encumbered with some difficulties we admit; but that in itself should have been a sufficient inducement to engineers and men of science to investigate the causes which lead to such a state of affairs, and suggest remedies either by practical examples or in their writings. Our scientific literature is almost silent on the subject, and our practice anything but what it should be. The lagging of boilers and the fitting of windsails, is considered to embrace everything essential—in fact, to leave nothing to be desired. And thus stokeholes are as hot now as they were in the first steamboats which crossed the Atlantic thirty years ago.

A steamer burning 50 tons of coal in twenty-four hours will require at least half a million cubic feet of air per hour for their combustion. The passage of such a great body of air at perhaps 60 deg., through a confined stokehole, would at first sight seem quite capable of keeping the temperature there within very reasonable limits. That it does do so to some extent is plain enough; if it did not, then no human being could endure the heat for ten minutes. That it does not do so in the fullest sense, is equally plain; and the reason is obvious. The heat within a stokehole is nearly all radiant. The ashpits, the smoke-box doors, the steam-pipes, the up-take—in short, nearly every portion of the boilers radiate more or less heat; and the incoming current of air cannot possibly prevent this dissipation of caloric, because heat will radiate in the teeth of the most powerful current of air we can command. A thermometer, usually hung in some situation where it is more or less protected, gives no idea whatever of the actual state of affairs. On the level of the floor-plates, at a short distance in front of the boilers, a thermometer placed in the full glare from the ashpits, will indicate, if protected at the back from the current of air, a temperature which will rather surprise those who try the experiment for the first time. Under the deck beams, over the boiler, and in out-of-the-way corners, the mercury will stand very much lower, while just under the ventilators or windsails it may not indicate 60 deg. It is difficult to find any situation other than a stokehole, where so many different temperatures may exist within a few feet of each other. Now we do not pretend to assert that any possible contrivance which can come into practical use on ship-board, can render boiler-rooms really—not comparatively—cool; but we believe that they might be rendered a great deal cooler than they are now by proper arrangements. The first consideration must be the prevention of radiation; the next, the diffusion of the entering air, so that every portion of the stokehole may have its due share.

The greater proportion by far of the radiated heat proceeds from the ashpits, the inclination of the grates aiding materially to this. Many well-constructed boilers are fitted with ashpit dampers. If these are all closed, as well as the fire-doors—although really very little air now passes through the stokehole—it will, however hot previously, become at once endurable. The converse of this experiment is found in throwing open the fire-doors and ashpit-dampers simultaneously; no amount of air can then render or maintain the temperature other than excessive to a degree. Yet, in the latter case, there is no doubt that ten or twenty times the quantity of air passes through the ventilators that did in the preceding experiment. This is tolerably conclusive evidence that the introduction of a great body of air can never accomplish the end in view, unless aided by other expedients.

The locomotive engine-driver is never exposed to any considerable temperature so long as the fire-door is shut, solely because iron plates at 300 deg. or 350 deg. radiate little heat; but were the ashpit mouth placed on the foot-plate, the case would be far different. It is not impossible that, ere many years pass away, boilers of the locomotive type will find their way into general use in our marine; indeed, such boilers have been employed before now with very good results. In such a case, it might not be difficult to fit one entrance to the ashpit under the barrel of the boiler, and away from the stoker, while a door might be provided beneath the fire-door, through which the ashes could be removed. These boilers would have fire-boxes resembling, more or less, that of the locomotive. The grates would be distinguished for breadth rather than length, and, as a consequence, the labour of the stoker would be very much reduced. Small fire-doors could then be employed, through which little heat would radiate when opened, especially if they were placed high over the grate, a clinker door beneath, rarely opened, serving to clean the fires. All this, however, is to a certain extent prophetical, and so far not practical. Much may be accomplished with the existing boiler; and to it the engineer who really wishes to ameliorate the stoker's condition, will naturally turn his attention. Nothing is easier than to fit a sheet-iron curved casing in front of the boilers, made in sections, and hinged to each dead plate just under the fire-door, reaching from thence to the floor-plates; this casing would form a continuous and roomy wind-trunk, supplied at each end with air from the down trunks of two or more large sheet-iron windsails. Any section could be raised with ease on its hinges, to clear the space beneath the fires. It would be quite unnecessary that the joints should be air-tight, the casing being intended merely as means of protecting the stokers from the radiant heat of the ashpits. Dampers in the wind-trunks would regulate the fires to perfection, and the entire arrangement would be simple, removed in a moment if occasion required; and taking up very little room, would really not at all interfere with the proceedings of the stokers, once they became accustomed to it.

In the smoke-box doors we have another source of radiant heat, which, if less powerful than the ash-pits compensates for that circumstance by offering an immense surface. So long as flame is suffered to exist in the up-take, it is ridiculous to expect these doors to remain cool. The 3-in. tubes of a marine boiler are, if short, easily traversed by flame when the furnaces have a good draught; and, as a consequence, it is not unusual to see smoke-box doors hot enough to glow in the dark now and then, if the fires are urged a little. The guard-plates put within them on studs are seldom or never sufficient to prevent the transmission of a great quantity of heat to the stokehole; and fire-clay linings, which have been tried before now, are heavy and troublesome. A better plan is to provide a false door outside, which can be easily fitted in such a manner that a constant current of cool air will pass between it and the real door into the funnel casing. The importance of lagging boilers thoroughly is too well understood now to require comment.

However carefully the radiation of heat is prevented, no stokehole can be cool unless the distribution of the air entering to supply the fires is carefully attended to. The best arrangement for the boilers is that which places them at the sides of the ship, with the furnace doors

opening on a central passage running fore and aft. In deep ships, the deck immediately above the stokehole should consist of a grating running its entire length. This is often omitted, the air being introduced through windsails frequently reaching nearly to the floor-plates. Such arrangements occasionally increase the draught, but they add materially to the temperature to which the stoker is exposed, and are objectionable in consequence. Single-decked ships are fitted sometimes with a grating of considerable size, just above the firing place; in other cases, merely with one or two large apertures; the entering air then descends straight to the fires. A man standing directly in the current may possibly find it cool enough, while along the sides of the ship the temperature is fearful. The best results are obtained by combining windsails, having trunks reaching far down beneath the deck, with very large open gratings. The fresh air descends freely, unopposed by the heated atmosphere which ascends through the gratings. The descending trunks can easily be arranged to distribute the air equally to every part of the stokehole, thereby materially aiding the draught. In the Navy, the plan of using lattice bulkheads between the engine-room and the rest of the ship has been lately introduced with manifest advantage. It is obvious that this scheme secures the diffusion of the air in the best possible manner. Its introduction in bulk is always to be avoided on principle, and its admission through numerous apertures can easily be secured in practice. The general ventilation of ships should receive far more attention than it does; and both the engineer and the naval architect will find the subject fraught with interest, tending as it does to the health of the crew, the comfort of passengers, the durability of the ship, and the good condition of cargo.

THE BRITISH ADMIRALTY.*

We lately directed the attention of our readers to what we consider an interesting comparison between the English and French Navies. In the course of our critique on Mr. X. Raymond's book, we mentioned that the most striking part of the work is the exposure of our incapable Naval Administration. Now M. Raymond is no jealous-eyed critic. He is not bitten with Anglophobia. He is neither burning to avenge Trafalgar and Waterloo, nor penetrated with the mission of sweeping our flag from the seas. Quite the contrary. It is true that his pride in the success and rapid progress of the French Navy during the last fifty years makes him inclined to annex rather too much honour to his own country; but his sympathy with English self-help, self-government, and free-trade makes him, on the whole, as fair and candid towards England as could be expected. It is with no malignant spirit that he points out the defects—too well known in our own country—of our Naval Administration. It is as a friend to England, and as a partizan of the Anglo-French alliance, that he points out the shortsightedness and inefficiency of the Board of Admiralty. He is one of those "who believe that the maintenance of good relations between France and England is a duty of the two countries—is a benefit for the whole human race. . . The continual failures of the Admiralty are much to be regretted by the French themselves, as they indirectly cause distrust against France, which mars a good understanding between the two countries. It is not in human nature to voluntarily confess its faults; and when the Admiralty meets with some fresh mishap, when it sees itself manifestly left behind in the race for superiority in the adoption of any new invention, the Board at once employs a certain proceeding—as yet always successful—which is certainly not calculated to keep up a reciprocal sympathy between the two nations. This proceeding is the greatest proof of cleverness the Board has yet given, but it is a proof of a hateful cleverness. Instead of confessing its faults with some approach to honesty, the Admiralty raises a great outcry against French ambition; it accuses us of plots and plans of invasion—accusations which nothing bears out; it stirs up the spirit of the nation against us; and in the meantime the Board obtains hundreds of millions of francs to make up for past errors." . . The injury done by the mismanagement of our Naval Administration does not end in England. This management, with its perennial crop of blunders, gives rise to a dangerous misunderstanding in France itself. Ill-informed people amongst the French — judging England by what they see at home—fancy that the Admiralty is the true representative of England's power; they do not perceive that the Admiralty, as constituted at present, "is but a detail, a fraction of the budget, a first stake in the game," is but the vanguard of England's naval power; and drawing conclusions from circumstances they do not understand, they indulge in the most extravagant fancies. "Would it not be better for us French if the Admiralty never fell into such a ridiculous and dangerous position?"

Such is the spirit that has inspired Mr. Raymond's severe remarks upon the constitution of the Board of Admiralty. Most Englishmen would feel in a like way; but the recollection of the enormous sums already wasted through mismanagement of the estimates, frequently doubling the total amount of the French maritime budget with less material produce in ships, would give additional intensity to an expression of feeling by any unfortunate ratepayer.

A great weakness in the present constitution of the Admiralty consists in the fact that no single member is responsible for the collective acts of the Board. The First Lord is only nominally responsible, as the presence of three members is required to form a legal decision upon any important matter. Again, the First Lord is, as a rule, merely a political personage; is totally ignorant of maritime affairs; and his proposals can be at any time overwhelmed under a deluge of technical objections from the four professional members of the Board. Both the executive and deliberative powers are thus virtually vested in the hands of the four professional members of the Board. What is the result? As M. Raymond asks: —"Do you know four doctors agreeing on the best way of treating a malady—four theologians agreeing on a question of philosophy—four engineers, on the best means of, say, getting rid of the sewerage of London? Then why expect four ship-captains to agree in a question of discipline—of administration—of sanitary arrangements—of armament—of construction?" The sitting is raised; the question is shelved; and subaltern routine continues to royally spend the money of the public. At last, the Board wakes up some fine morning to find that the Navy "must be reconstructed," or that hasty, and therefore most expensive efforts must be made to catch up the advance gained by other nations. Frederick the Great used to say that "there is something worse for an army than a bad general, and that is—two good generals." But the hexarchy of the Admiralty Board is not always composed of good generals, or rather of good seamen. Chosen for political seasons, and subject to the vacillation of party warfare, the average existence of Admiralty Boards seldom exceeds two years; and thus, of the two estimates for which the Board ought to be responsible, one is perhaps already half-spent when the existing Board arrives at this helm, and the second estimate has to be accounted for by the succeeding administration.

The eccentric character of the Board does not confine itself to its constitution, but also extends to its composition. Of the six Lords of the Admiralty, two are Members of Parliament professionally unconnected with the Navy, and the other four are exclusively and simply captains of men-of-war. Not one of the other important specialities composing the naval establishment of a nation is represented at the Board. The four naval commanders are in the majority, and are the actual "masters of the situation." The other branches of maritime affairs—such as hydraulic works, shipbuilding, ordnance, sanitary and other matters—are, one and all, utterly unrepresented at the Board. As is well known, powerful causes of jealousy always exist, in all countries, between the builders of ships and the sailors of ships. In England, the sailors and fighting men have been allowed to utterly suppress their civilian adversaries. The management of the shipbuilding department, is, was, and perhaps always will be completely in the hands of sailors; and Sir Robert Sepping, Sir William Symonds, Sir Baldwin Walker, and Admiral Robinson were successively chosen from the class of ship-captains.

Again we ask, what are the results of the system? In mere quantity, the work turned out by the Admiralty Board during the last fifty years, is less than the amount done by the French Naval Administration, with half the expense. The results in *matériel*, viz., ships, hydraulic and other works, are quite out of proportion to the relative amounts of the French and English naval budgets. In quality, the work performed is far behind that of the French—who have beaten us in the race of progress towards improved means of attack and defence; who have forced us twice to reconstruct our Navy; who have forced us to improve our artillery; who have thus successfully encountered us in what we vainly imagined was our own ground—the application of steam and of iron to naval construction and warfare. "The foresight of the Admiralty is continually at a loss; and it does not even know what is going on in its immediate neighbourhood." The life of the Admiralty seems to be passed in a deep and peaceful slumber, only occasionally disturbed by intermittent and sudden rousings by the House of Commons. At the end of every seventh year, the Sleeping Beauty of Somerset House is subject to a short period of wakeful and even feverish anxiety, to again subside into the enchanted seven years' sleep. In 1851, the House had to force the Admiralty to give up sailing vessels—seven years after they were abandoned by the French for war purposes. Four years after the French had given up auxiliary steamships, the Admiralty—suddenly perceiving that France had more auxiliary steamships than England—determined to "rebuild the fleet." The time was well chosen. All the world knew, except the Admiralty, that the French had not built a steam-vessel since 1855. Any one, except the Admiralty, could, during a whole year previous to 1859, have seen the "Gloire" in the docks of Toulon. Another seven years' period passes away; another Naval Administration battle is fought and won in the House of Commons, and the Board unwillingly [illegible] wooden s[illegible]

* Les Marines de la France et de l'Angleterre. Par Xavier Raymond. Paris and London: Hachette, 1863.

As M. Raymond says:—"If this is not improvidence and carelessness, no such qualities exist on earth." As to order in money matters of naval officialdom, we all remember how Lord Clarence Paget, in 1859, showed that a million sterling is annually engulphed in the hands of the Admiralty—no one knows how, and no one can account for its disappearance. As to the order and discipline amongst our seamen, we all too well remember the late disgraceful mutinies in the "Princess Royal," the "Liffey," and the "Marlborough." The happy audacity of Lord Clarence Paget is now enlisted in the service of the present Admiralty; the reformer out of office is now a Conservative official. The usual septennial slumber of the Board elapses in 1868. Supposing that in that year we are still blessed with Lord Clarence Paget in his present position, or even supposing that another special pleader be retained for the defence of the Admiralty, what would we not give to know the fresh seven years' blunder that will have to be excused and made good by the millions of the nation!

AERIAL NAVIGATION.*

WHILE M. Nadar is preparing to try an experiment which I venture to say is quite certain to be a failure, I propose to take advantage of public attention being attracted to the subject by his doings to invite some consideration of the principles which bear on the matter, and to endeavour to show that, while the air can never be navigated by means of a mere balloon, however big, we may, nevertheless, begin to navigate it as soon as ever we choose.

"If any new triumph of science could astonish us in these days," says Vespertilio, "it would be the success, however imperfect, of any attempt to navigate the air." After discussing the matter through nearly two columns of the *Times*, he came to the conclusion that "the problem of aërial navigation will be easily solved whenever the progress of science shall place us in command of a motive power considerably lighter, in proportion to its capacities, than the steam-engine, *and not till then*." As by far the larger number of all who have of late years given attention to this subject have come to precisely the same conclusion, to call it in question may augur some audacity; but I believe it may be readily shown that this conclusion is fallacious, and that we have *already* at our disposal the means of at least partially solving the problem to which it refers—of solving it, that is to say, *as far as it ever will or can be solved, except in relation to the question of speed.*

It should be clearly understood, at the outset, that balloons do not solve it. "Balloons," wrote Vespertilio, "do not navigate the air—they only float on it in utter helplessness." We are all familiar enough with the sight of these machines moving majestically over our fields and cities. A balloon ascent forms part of the programme of almost every popular out-door *fete;* and when the balloon retouches the earth it is always at some distance from the spot from which it ascended. The horizontal motion which it thus performs, however, is motion only in relation to the earth; except in ascending or descending, a balloon never moves in relation to the atmosphere. It may travel over land or sea, for hours together, at the rate of scores of miles an hour; but, unless it shall have varied its *elevation* during the voyage, it will occupy precisely the same place in the atmosphere, and be surrounded by the same identical particles of air, at the conclusion as at the commencement of its journey. An aëronaut, seated in the car of a balloon, may vary at will, within certain limits, the degree in which he and the machine which buoys him are elevated above the earth. He may at pleasure, under certain conditions and within the limits alluded to, either rise into higher or descend into lower regions of the aërial ocean in which he is suspended; but in this power to ascend or descend lies his only control over other the direction or the length of his aërial journey,—and he can have no control at all over its speed. His only horizontal motion must be in the direction of the current he is in, and his rate of motion cannot in the least differ from its rate. He can move neither against the current, nor across the current; and in the direction of the current he can only move just as fast as it moves. He cannot move either faster or slower, not even to the extent of an inch a day. At present, therefore, balloons, as regarded as a means of conveying passengers or merchandise from place to place, have no practical value whatever. They have been made useful in military reconnoitering, and Mr. Glaisher has made them serve the interests of meteorological science; but they have *not* yet been made to navigate the air. And it is not too much to say that they never can be made to navigate it. Even if, by some inconceivable means, the power of an engine could be applied directly to a balloon, so that the centre of effort would be rendered coincident with the balloon's centre of gravity, the balloon could be made to go through a few wild gyrations; but, owing to its globular shape, its propulsion in any steady straighforward, horizontal course would still be impossible. It is useless, therefore, to dream that the air can ever be navigated by means of balloons. Balloons will never be able to do more than just carry a few passengers, or a few light loads of merchandise, in the direction, and at the speed, of whatever current may chance to be prevailing at the place and at the time at which the experiment is made.

Seeing the utter hopelessness of the idea of navigating the air by means of balloons, Vespertilio, as so many others have done, came to the conclusion that if men are ever to accomplish aërial navigation it must be by means of machinery constructed upon the model of the wings and attendant apparatus of "flying animals." Vespertilio's favourite "flying animal" is the bat—hence his choice of a signature; but as there is little essential difference between the principles which govern the flight of bats and those upon which the flight of birds is effected, and as birds are by far the pleasanter things of the two to write about, the latter are the only "flying animals" that will here be further spoken of. In Dr. Carpenter's "Animal Physiology," the means by which they raise themselves into the atmosphere, and sustain themselves in it, are thus described: "The action of their wings is such that the air is struck with less force during the up-stroke than during the down-stroke; otherwise, the effect of the former would neutralize that of the latter. This is accomplished partly by the greater velocity of the down-stroke, as compared with the up-stroke, which causes the resistance of the air to be much greater in the former than in the latter. But it is by the alteration of the surface of the wing, as it acts upon the air, that the chief difference is made; the arrangement of the great feathers being such that they strike the air with their flat sides, but present only their edges in rising." Now, it has usually been supposed that almost the only difficulty in the way of the successful imitation of the flight of birds consists in the circumstance that the latter are able to move their wings with an immensely greater force than—considered weight for weight and bulk for bulk—either a man or a steam-engine is capable of exerting. The Vespertilios have assumed that a man could navigate the air by means of a machine provided with artificial wings, if he could work these wings with a degree of force corresponding with that with which a bird works its wings; and hence they have been constantly crying out that a source of motive power sufficiently lighter than the steam-engine is all that they want in order to enable them to fly. I shall show below that this notion is an utterly mistaken one; but, assuming for the moment, that it is sound, let us inquire *how much* lighter than the steam-engine the motive power must be which would be requisite to enable a machine to raise itself into, sustain itself in, and propel itself through the atmosphere, by means of artificial wings. This is a branch of the subject which the Vespertilios have never gone into, notwithstanding that the calculations may be very readily made. It is known, to begin with, that "the swallow, *when simply sustaining itself in the atmosphere*, is obliged to use as much force, *merely to prevent its fall*, as would raise its own weight twenty-six feet in a second." In estimating the "horse-power" of steam-engines, the measure of the power of one horse is considered to be the ability to raise 33,000 lb. to the height of one foot in a minute. As 33,000 lb. are equal to about 14¾ tons, it will come to the same thing, if, instead of regarding one horse-power as the ability to lift 14¾ tons one foot per minute, we regard it as the ability to lift one ton 14¾ feet per minute. Twenty-six feet in a second is at the rate of 1,560 feet in a minute, and 14¾ into 1,560 goes very nearly 108 times. Consequently, to simply sustain in the atmosphere a machine constructed upon the model of the swallow, and weighing, with all its cargo, just one ton, would require the exertion of a force equal to that of a steam-engine of 108-horse power, even supposing that this machine were *an exact reproduction* of its model, as regards its form and the relative size, weight, and strength of all its parts, and that it were as *perfectly constructed* as the wonderful living organism it was designed to imitate. It is quite clear, however—to take the latter point first—that it could not be thus perfectly constructed. Let it be constructed only one-fourth as perfectly—if one may use such an expression with refernnce to a degree of perfection which is infinite of its kind—and it would be by far the most marvellous piece of mechanism that human skill ever contrived. This at once raises the required force to 432-horse power; and even that would not be enough, inasmuch as the *design* of the model could not be imitated any more successfully than its construction. The artificial wings, for instance, could only be moved by means of "levers of the second kind"—a kind of lever, of which a butcher's "steelyard" affords the commonest example. Owing to the aërial machine having to be constructed of some material much heavier, in proportion to its bulk, than the bodies of birds are, while the superficial extent of the wings would have to be proportionate to the weight rather than to the bulk of the machine, the short arms of these levers would be obliged to be much shorter, in proportion to the length of the long arms, than is the case with the levers which move the wings of birds. As whatever power was applied to the artificial wings would have to be applied to the ends of the short arms of the levers in question, it would thus act at an enormous disadvantage, and that disadvantage would be very greatly increased by the impossibility of imitating to more than a very limited extent the beautiful arrangements which cause the wing of a bird to experience much less resistance when moving upwards than when moving downwards. It is not merely, as quoted above, that "the arrangement of the large feathers is such that they strike the air with their flat sides, but present their edges in rising," but *all* the feathers "are so placed with reference to each other that in the upward stroke they tend to separate and allow the air to pass between them, while in the downward stroke they are pressed against each other so as to present to the air an impervious expanse, and thus to secure the greatest possible amount of atmospheric resistance." At the best, this arrangement could be imitated but very imperfectly, while the *elasticity* of the wing of the swallow could not be imitated at all in any artificial wings large enough and strong enough to enable them to sustain the amount of atmospheric resistance which they must be able to sustain in order to lift and support a ton. Such wings must necessarily be rigid; and moreover, must be very much heavier, in proportion to their size, than the wings of birds. It is certainly under the mark to say that all these disadvantages, acting together, would render it impossible for any artificial wings to be moved with force enough to enable them to support a ton in the atmosphere, except by a force at least four times greater than would have been sufficient for this purpose could the wings and the apparatus for the application of power to them have been accurate imitations of those of the swallow, differing from these only in being superior in size and inferior in excellence of construction. A winged chariot, weighing, with its contents, only one ton, would thus require a force equal to the power of 1,7[illegible] horses simply to sustain it in the atmosphere, after it had been raised thereinto by the exertion of a still greater force, and without propelling it an inch in any direction. Making allowance for the additional force necessary, first to raise it into the atmosphere, and afterwards to propel it while sustained therein, 2,000 horse-power may certainly be said to be the very least that would enable a machine weighing a ton to navigate the air by means of artificial wings. Supposing, therefore, that there were no other ground of objection to the artificial wing idea than this, before it can be carried into practice some engine must be invented which shall be so light that, with all the requisite appliances—including the wings, whatever food the engine may require, and the "car," or other receptacle for passengers and cargo—it shall not weigh more than one ton for every 2,000 horse-power it can as[illegible] The wings, indeed, would necessarily be of [illegible] great weight that for each ton which engine [illegible] and wings together might weigh, probably not [illegible] than a quarter of a ton would be available f[illegible] engine—and even this allows nothing for t[illegible] sengers and cargo. I believe that no steam [illegible] of 2,000 horse-power has yet been con[illegible] which, with its boilers, the water in them [illegible] hour's consumption of coal, and water [illegible] replenish the boilers during twelve hou[illegible] would not weigh at least 300 tons, or m[illegible] thousand times the weight of an engine li[illegible]

* "Weldon's Register of the Arts and Sciences."

to "solve the problem of aërial navigation" on Vespertilio's plan, even were a sufficiently light engine all that is required to do that. Improvements conducive to lightness are constantly being made in steam-engines; and other sources of motive power are being discovered, and will, doubtless, be rendered practically available in time. But if men are not to navigate the air until they can construct an engine which, while weighing only a quarter of a ton, shall be able to put forth as much force as the paddle-engines of the "Great Eastern" can exert, the air will *not* be navigated until long after the present generation shall have been gathered to its fathers.

The exceeding lightness requisite in the engine which must move them, is not, however, the only obstacle to the navigation of the air by means of artificial wings. There is, as hinted above, another difficulty in the way, and one which would render such navigation impracticable, on any extensive scale, even if we had engines of 2,000 horse-power weighing, not even a quarter of a ton, but, suppose we say, only a quarter of an *ounce*. It consists simply in the circumstance that for an aërial machine sustained by the motion of wings to be able to support a ton, including its own weight, the wings of the machine must be of such enormous size, that—so far, at least, as we at present known—there is no substance in nature strong enough to make levers with which to move them. Even, therefore, if we had an engine which, while capable of putting forth any required amount of force, should weigh absolutely nothing at all, the transport of passengers or merchandise by means of artificial wings would still be as impossible as it is at present.

And yet man may navigate the air if he will, and as soon as he will. To the question—"If by means neither of balloons nor of artificial wings, then by *what* means?"—I reply: by imitating, not the Birds, but the Fishes.

The birds and the fishes constitute the only examples we have in nature of animals being able to sustain themselves in, and at the same time to propel themselves through, an element lighter than the heaviest portions of their own bodies. We have seen by what means the birds do this, and that we cannot imitate them. In the case of the fishes, the matter is managed in another way. Unlike the bird in flying, the fish in swimming has no weight to bear, and so all the exertion it needs to put forth is for the purpose of propelling itself. The greater portion of its flesh and bones is of as nearly as possible the same specific gravity as the element which it inhabits, and the excess of weight of the heavier portions is balanced by means of a long narrow bag filled with some gaseous body by many more times lighter than water than hydrogen is lighter than atmospheric air. As a whole, the body of the fish is rendered of exactly the same weight as the quantity of water which it displaces, and it is, therefore, sustained in the water just as a balloon is sustained in the atmosphere; and this, too, at least to some extent, by exactly parallel means. For man to navigate the air, the machine by which he does so must have thus much in common with the balloon—it must be as self-buoyant in the element it has to travel as the fish is in *its* element. Therefore, although balloons cannot accomplish the navigation of the air, it can be effected only by the aid of those light gases by means of which balloons are rendered buoyant. The object in view can only be achieved by some method of applying the lifting power of the light gases more advantageously than this is done in the case of balloons. That method can only consist in an alteration of the *form* of the receptacles containing the gas. Instead of being spheroidal, they must be more or less fish-shaped; *they must be flattened cylinders with paraboidal ends.*

In order to show clearly, by a readily intelligible illustration, what influence this simple change of form would have, let us suppose a hundred balloons, all of exactly the same size, to be ranged in a row, like the carriages of a railway train, and let the hundred balloons be all connected with, and all assist to support, one long, narrow car. Such a train of balloons would represent the proposed cylinder sufficiently nearly—especially as the "cylinder" would itself virtually consist of a number of distinct bags of gas connected together, the chief difference between it and the train of balloons being that in it space would be economized, and steadiness of lifting power and uniformity of motion secured, by there being no such interstices between the bags of gas composing it as there would be in the case of the train of balloons. It is obvious that, to the motion through it, end-foremost, of the supposed train of balloons, the atmosphere would be able* to oppose only the same amount of resistance as it would oppose to the motion through it of any one of the balloons singly. No more force, therefore, would be required to propel the train of balloons than would be required to propel a single balloon, but the train would be able to lift an engine for the supply of that force a hundred times heavier than the single balloon could lift. As the power of an engine increases much more rapidly than its weight, there could thus be applied to the propulsion of the train of balloons several hundred times more force than could be applied to the propulsion of any one of them by itself.

I have said that the aërial cylinder which this article is written to suggest would consist, in effect, of a combination of a number of separate bags of gas. It would never do to make it consist simply of one huge long narrow bag; because such a bag, if filled with a light gas and allowed to rise in the atmosphere, instead of floating horizontally, as the cylinder must, in order to be available as a means of navigating the air, would float with its longest axis vertical to the earth's surface. To prevent its doing that, the cylinder, when not actually composed of a number of distinct bags combined together, should be divided into a number of separate compartments or cells, each of which should be higher than it was wide—should be longer, that is to say, in the direction perpendicular to the longest axis of the cylinder as a whole than in the other direction. It will readily be seen that by this simple arrangement it would be secured that it should be impossible for the cylinder to float in any other way than horizontally.

That such a cylinder could be propelled, and by such means for the supply of motive force as we have already at our command, is not a merely speculative opinion—an enthusiastic conviction, which may or may not be well founded. It rests on data which have long been established, and have been tested by actual experience thousands of times. It is based on the following established facts:—

1. The weight of a cubic foot of hydrogen is 36·5 grains, and that of a cubic foot of atmospheric air 523 grains. A cubic foot of hydrogen will, therefore, sustain in the atmosphere a heavy body weighing 486·5 grains, being the difference between its own weight and that of the volume of air which it displaces. There are 7,000 grains to the pound avoirdupois, and 14·5 times 486·5 is 7,054·25. Consequently, 14½ cubic feet of hydrogen will sustain a pound and 54·25 grains.

2. A body moving through the atmosphere at the rate of one mile an hour, and presenting a flat surface for the atmosphere to act upon in opposing its motion, experiences a resistance of ·005 of a pound on every square foot of such surface, and this resistance increases as the square of the velocity.

3. "This resistance to motion through the atmosphere is greatly modified by the form of the moving body. The form that gives least resistance is nearly that of a parabola, or a form somewhat resembling the breast of a duck or the head of a fish. The body should also taper backwards, like the body of a fish." The resistance to a paraboloid is one-third less than the resistance to a plane suface equal in extent to a section of a paraboloidal body, taken at its widest part.

From these data, both the lifting power of a cylinder of any given dimensions, and the resistance which the atmosphere would oppose to its motion, at any given speed, can be readily calculated.

Let us suppose, then, a cylinder of the kind indicated, to be 60 ft. long, and to average 12 ft. high and 8 ft. wide. Such a cylinder would contain 5,760 cubic feet, and the lifting power of that quantity of hydrogen would be 400 lb. Supposing the silk, and whatever apparatus the cylinder was furnished with, to weigh 260 lb.—in reality it need not weigh nearly so much—there would still remain a lifting power sufficient to lift and sustain a man weighing ten stones. A man of ordinary strength is able to lift 6,000 lb. to the height of 1 ft. in a minute, when applying his strength under fair mechanical advantages. Five miles an hour is 440 ft. in a minute, and 440 into 6,000 goes 13⅓ times; so that the strength of one man, applied under proper conditions, would be sufficient to lift 13⅓ lb. 440 ft. in a minute. A plane surface, moving through the air at the rate of 440 ft. in a minute, or five miles an hour, would experience a resistance of twenty-five times ·005, or ·125, of a pound on every square foot; and if the plane surface were equal in extent to the largest section of the proposed cylinder, it would thus experience a total resistance of 14 lb. In the case of the cylinder itself, owing to the paraboloidal form of its ends, the resistance would be a third less than this, reducing the total to 9⅓ lb. To propel this cylinder at the rate of five miles an hour would, therefore, require the exertion of a force capable of lifting 9⅓ lb. 440 ft. in a minute. We have seen that a man of ordinary strength could lift 13⅓ pounds 440 ft. in a minute. Consequently, he could propel the cylinder, at the speed mentioned, with great ease.

I venture, therefore, to repeat that we have *already* at our disposal the means of navigating the air.

WALTER WELDON.

* That is, except in so far as the circumstance of the side of the train of balloons presenting, not a uniform flat surface, but a series of bulging projections, might increase the hold of the atmosphere. In the case of a cylinder of the kind suggested in the above article, holding a hundred times as much gas as a balloon whose *side* should present just the same amount of surface as either *end* of the cylinder, the case would be *exactly* as stated in the text.

THE "ROYAL SOVEREIGN."

THE "Royal Sovereign's" turret "machinery," with the bed upon which it rests, we will now endeavour to describe, premising that the diameter of the turret is less than that of the turn-table or the machinery upon which the turret revolves. Level with the ship's lower deck, or, as it now must be, her main and lower deck both, upon upright timbers from the ship's keelson, are laid logs of teak about 20 in. square, and extending over a space of nearly 80 ft. in circumference. On these square timbers has been constructed the bed proper which supports the turret, turn-table, and machinery. It is in appearance a gigantic cartwheel, 26 ft. in diameter, the nave and periphery being constructed of English and American oak, the periphery entirely of banded strips of American, and the spokes of English oak. The periphery of the wheel measures 24 in. by 12 in., and the spokes each 18 in. by 12 in., all fitted with the nicest accuracy and bolted down immoveably to the square logs of timber resting on the uprights underneath. The axle to this monster wheel exists in the iron cylinders which will give entrance to the magazine below from the turn-table, and which, 26 in. in diameter, 7 ft. 6 in. in length, and 3 tons each in weight, are fixed upright through the centre of the wheel's nave; two cast-iron collars, each 6 ft. in outer diameter and each some hundredweight, being fixed, one on the upper and the other on the under side of the deck, and securing the axle or cylinder thus in its position immoveable as a rock. The upper part of this cylinder, therefore, projects upwards of 2 ft. from the wheel's nave, and becomes the pivot upon and round which the turn-table and turret revolve. From a brass collar which encircles this cylinder, next the nave of the wheel, radiate outward 24 iron rods, on the outer ends of which are fixed 24 bevelled iron wheels, 18 in. in diameter and 19 in. broad, and which, set in a double circular iron framing, work round a metal roadway laid on the periphery of the wheel, a second brass collar round the cylinder being fitted with a set of small brass bevelled wheels, the turn-table thus fitting over and round the cylinder or axis, and resting with its inner circumference on the small brass rollers, which encircle the cylinder, and its outer circumference, upon the 24 bevelled wheels, which work upon the iron roadway laid upon the periphery of the wheel. Every part connected with the ironwork of the turret, and which is being executed under the superintendence of Mr. A. Murray, Chief Engineer to the Admiralty at Portsmouth, is very massive in its character, and is beautifully finished, and, so far as any judgment may be formed at present, there is nothing to suggest the slightest fear of the "Royal Sovereign's" turrets revolving freely under the heaviest storm of shot that can be brought to bear upon them, or under circumstances of the greatest possible inclination that may be given to the ship's deck in the roll and tumble of a channel-sea. Revolving on an immoveable central axis as does a steamship's paddlewheel, it certainly appears that even 15 or 20 deg. of inclination should not interfere with the turret's working.—*Times.*

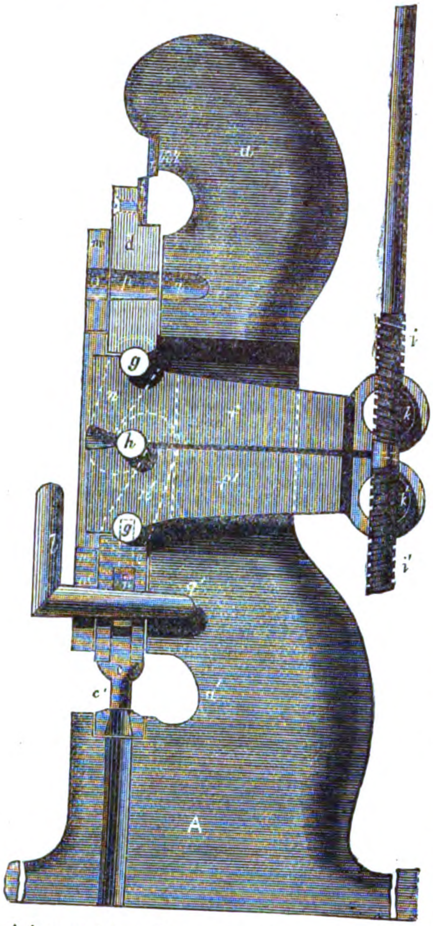
The Paris Correspondent of the *Building News* states that there is to be a combined French and Spanish Exhibition at Bayonne in 1864, which is to include objects connected with Architecture, the Fine Arts, Engineering, Mechanics, and Agriculture.

Some alterations are ordered in the sights of the pattern Armstrong guns. The frail traject-sight is abolished, and the system of double sighting on the trunnions of all field guns is to be adopted.

MACHINERY FOR PUNCHING AND CUTTING METALS.

LETTERS PATENT have been granted to M. A. F. Mennons, home and foreign patent agent, Paris, for the invention of "Improvements in Machinery for Punching and Cutting Metals"—a communication from Nicolas de Telescheff, (Captain of Artillery), St. Petersburgh, Russia.

This invention consists in an improved combination of mechanism, applied to the construction of punching and cutting machinery, as shewn by the annexed drawing, which is a vertical section of the apparatus.



A is a cast-iron frame, carrying at its upper part *a* the shears *b*, b^1, and at its lower part a^1 the the punch *c* and bed plate c^1. The lower shear blade and the punch are mounted on vertical slide bars *d* and *e*, operated by the horizontal levers *f*, f_1. *g*, g^1, are pivots or trunnions fixed to the slide bars, and bearing on the fore ends of the levers *f* f_1; *h* is a moveable axle, placed between the levers, and serving as a point of rotation to the coupling hooks *n*, *n*, by which these levers are connected with the slide bars. In the tapped bearings *k*, k^1, adjusted to the hind extremities of the levers, passes a screw *i*, i^1, threaded to the right over one half of its length, and to the left in the other half, and provided at the top with a hand bar or wheel of any suitable form. *o*, *p*, *q*, o^1, p^1, q^1, are gorges formed in the plates *m*, the slide bars, and the frame, to receive the conical keys *l*, *l*, by which one of the two slide bars is kept stationary, while the other is at work.

To cut the metal with the machine constructed as above, the keys *l*, *l*, are inserted, as seen in fig. 1, in the lower gorges, thus securing in position the punching apparatus. The screw *i*, i^1, is then turned from left to right, and by its action on the cylindrical bearings *k*, k^1, causes the hind extremities of the levers *f*, f_1, to separate, while the front ends close on each other in turning on the axle *h*. The traction exerted in this movement on the pivot *g* carries down the slide bar *d*, thus allowing the metal to be passed between the shears. The screw is then reversed, the hind extremities of the levers reclose, the fore ends reopen, and by their pressure on the pivot *g* force upwards on the metal the slide bar with its blade.

For punching, the keys *l*, *l*, withdrawn from the gorges o^1, p^1, q_1, to free the slide bar *e*, are set in *o*, *p*, *q*, and the shearing apparatus being thus secured in its turn, the levers *f*, f_1, are alternately opened and closed, under the action of the screw, in the manner above described.

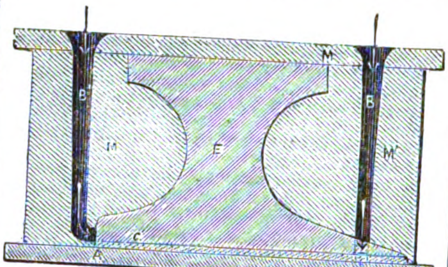
BROOMAN'S IMPROVEMENTS IN THE MANUFACTURE OF ANVILS.

LETTERS PATENT have been granted to Mr. R. A. Brooman, for improvements in the manufacture of anvils and other metal articles requiring hard surfaces—a communication from abroad by Louis Jules Duhesme, Alexandre Rey, and Ernest Muaux, all of Boutancourt, France.

The manufacture of anvils by the processes hitherto in use possesses great inconveniences. The steel table is often fixed in a defective manner to the iron which forms the remaining part of the anvil, and the anvils soon require repair or become altogether useless; they are besides very costly. The object of this invention is to overcome these defects.

The invention consists, first, in manufacturing anvils by the direct superposition during casting of two metals united so as to form one body; secondly, in the substitution of casting for forging in the manufacture of anvils, thereby diminishing in a great measure both hand labour and expense.

In a frame composed of two parts M, M^1 (see the accompanying drawing), properly adjusted, is



formed the mould, blacked with charcoal. There is nothing particular in this operation; any of the ordinary methods will answer. At the time of casting, the mould is arranged so that the surface, which is the counterpart of the table of the anvil, is at the bottom, where it rests on a plate of iron A. To form the table of the anvil, the patentee first runs into the mould E by the aperture B molten cast steel up to the point C, which point will vary according to the required thickness of the table. This operation should be effected quickly; then before the running in of the steel is stopped, but when the thickness of the steel is such as been previously determined upon, he runs molten iron into the mould through another aperture B^1 at that point to which the thickness of the table reaches. The two metals are run in together until the surface of the mass has attained a certain height; then the running in of the steel is stopped, while the iron is continued to be run in until the mould is filled. When the anvil has become tractable and sufficiently solid, it is removed from the mould, and the patentee avails himself of the heat it still retains to submit it to the subsequent stages of the manufacture, but generally subjecting it to a forge fire heated with coal and aided by a powerful blast, whereby the table is quickly brought to a red heat; he then hammers the table to render it compact and homogeneous; it is afterwards dressed or smoothened in the usual way. For the purpose of tempering, the anvil is again placed on the fire, and heated to a greater degree if possible than before, and then tempered by any ordinary process. Instead of employing ordinary cast iron, as before stated, malleable cast iron or Bessemer iron may be used.

CLARK'S IMPROVEMENT IN PISTON VALVES AND OTHER PISTONS.

THE following improvement in piston valves has been patented by Mr. William Clark, of Chancery-lane, engineer, being a communication from Mr. T. S. Davies, of Jersey City, U.S. This improvement is more especially designed for piston valves, but may be adopted in other kinds of pistons. It consists in the construction of such a valve, or of any piston with an expanding ring, having the head and follower fitted to its interior and with a dovetail wedge, so applied in connection with the ring head and follower as to make the valve or piston as much like a solid block as is desirable, yet capable of being set out to fit the cylinder in which it works and compensate for wear.

In the accompanying drawing, fig. 1 is a side view of the piston valve constructed according to this invention; fig 2 is a central section of the same; and fig. 3 is a central longitudinal section of the cylinder and steam chest of a locomotive, having a pair of such piston valves. Similar letters of reference indicate corresponding parts in several figures.

FIG. 1.

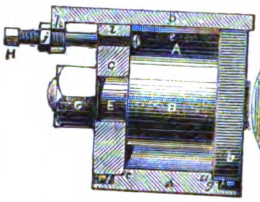


FIG. 2.

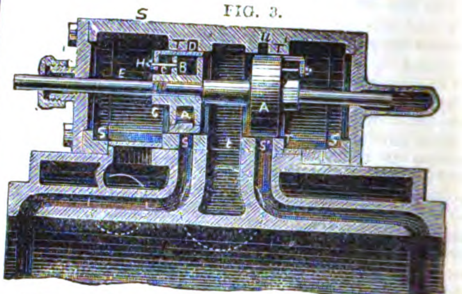
FIG. 3.



A is a single ring of cast iron, brass, or other metal, of a depth equal to the whole depth of the piston or valve, turned up externally to a cylindrical form to fit the cylinder or cylindrical seat, and having its interior turned out at one side concentrically to its exterior as shown at *a*, *a*, in fig. 2, for the reception within it of the flange *b* of the solid head B of the piston, and turned out at the opposite side in a similar manner as shown at *c*, in fig. 2, for the reception of the follower C. The said ring has cut in its exterior at any point in its circumference a taper dovetail groove *d*, *d*, for the reception of a dovetail wedge D, which is to be moveable parallel with the piston rod, and from the middle of the back of the groove the ring is cut through as shown at *l*, in fig. 2, to permit it to be set out by the dovetail wedge, the outer face of which combines with the periphery of the ring to make a complete cylinder. The solid head B is driven tightly on, or otherwise firmly secured to the rod E, and the follower C is fitted to the rod and secured by a nut G, fitted to a screw thread on the rod, the said nut holding it close up to the face of the head B and to the shoulder at the back of the recess *c*. The flange *b* has projecting from its periphery a short pin *f* to enter a notch *g* in the interior of the recess *a* of the ring, and the follower C has a similar pin to enter a similar notch in the recess *c*. These notches and pins prevent the head B, the follower C, and ring A, from turning independently of each other. The head B and follower C are received entirely, or almost entirely, within the ring A, so that the perispherical surface of the piston is unbroken, except at the junction of the wedge D; and the piston is almost like a solid block, though it can be expanded or set out against the exterior of its

cylinder or cylindrical seat as required to make it fit and compensate for wear by means of the wedge D. To provide for the convenient adjustment of the wedge D, there is applied a screw H, screwing through a tapped hole in a lug h at one end of the wedge, and having a journal i so fitted to a bearing in the follower C as to be capable of turning freely, but not moving longitudinally. This screw is fitted with a jam nut j, to secure the wedge in any position in which it may have been adjusted.

In applying piston valves for the induction of the steam to and from the cylinders of steam engines, there is provided within the steam chest S (fig. 3) a cylindrical casing or seat T, bored for the reception of the valves, which are two in number, and attached to the same stem or rod E, and the steam ports S, S[1], and exhaust port t are arranged substantially as for the D slide valve. As the outer ends of both valves are exposed to the pressure of the steam in the chests, and the inner ends of both are exposed to the pressure of the exhausting steam or of the atmosphere, the valves are perfectly balanced in a direction parallel with their axis; and to provide for balancing them in all directions radial to the axis, there are grooves u, of a width corresponding with the width of the ports s, and communicating with said ports cut all round the seat T.

BRITISH ASSOCIATION.

Mechanical Section.

An important communication on boiler explosions, from the Astronomer Royal, was read by Mr. P Le Neve Foster.

In considering the cause of the extensive mischief done by the bursting of a high-pressure steam-boiler it is evident that the small quantity of steam contained in the steam-chamber has very little to do with it. That steam may immediately produce the rupture, but as soon as the rupture is made and some steam escapes, and the pressure on the water is diminished, a portion of the water is immediately converted into steam at a slightly lower temperature and lower pressure, and this in the same way is followed by other steam at still lower temperature and pressure, and so on until the temperature is reduced to 212 deg. Fahr. and the pressure to 0. Then there remains in the boiler a portion of water at the boiling point, the other portion having gone off in the shape of steam, of continually diminishing pressure. From this it is evident that the destructive energy of the steam, when a certain pressure is shown by the steam-gauge, is proportional to the quantity of water in the boiler. By the assistance of Professor Miller, of Cambridge, Messrs Ransome, of Ipswich, and Mr. George Biddell, I have been able to obtain a result which I believe to be worthy of every confidence. I will first state, as the immediate result of Mr. Biddle's experiments, that when there were in the boiler of a small locomotive 22 cubic ft. of water, at the pressure of 60lb. to the square in., and the fire was raked out and the steam was allowed gently to escape with perfect security against priming, the quantity of water which passed off before the pressure was reduced to 0 was 2¼ cubic ft., or one-eighth of the whole. In regard to the use made of Professor Miller's theory, Professor Miller had succeeded in obtaining a numerical expression for the pressure of the steam at 12 different measures of the volumes occupied by water and steam, which expression I have succeded in integrating accurately, and I have thus obtained an accurate numerical expression for the destructive energy of the steam. In regard to the use of General Didion's experiments, giving the velocity of the ball in cannon of different sizes produced by different charges of powder, I have found which of these experiments exhibits the greatest energy per kilogramme of powder, and have adopted it in the comparison. The result is as follows:—The destructive energy of one cubic foot of water, at 60 lb. pressure per square inch, is equal to the destructive energy of two English pounds of gunpowder in General Didion's common experiments, which were made, as I understand, with smooth-bored cannon. It cannot be doubted that much energy is lost in the windage, some also from the circumstance that the propelling power ceases at the muzzle of the gun before all the energy is expended, and some from the coolness of the metal. If we suppose that from all causes one-half of the energy was lost, then we have this simple result:—The gauge pressure being 60lb per square inch, one cubic foot of water is as destructive as one pound of gunpowder. In one of Mr. Biddle's experiments the steam valve was opened rather suddenly, and the steam escaped instantly with a report like that of a heavy piece of ordnance. This is not to be wondered at, for it appears from the comparison that the effect was the same as that of firing a cannon with a charge of 44 lb. of gunpowder.

MODE OF RENDERING TIMBER-BUILT SHIPS IMPREGNABLE AND UNSINKABLE, UNDER MODERATE SCREW POWER, OR IN A LEAKY VESSEL.

Admiral E. Belcher read a long and interesting Paper on rendering ships unsinkable, by closely ceiling the holes under the planking of the hold beams, and saving those spaces between for the storage of light dry goods above the deck (which were generally lost), and placing loose planks as a temporary deck. In the event of a dangerous leak, or even a large hole being stove in the bows or bottom of a vessel, he proposed securing the hatches from beneath and the hatches from above, screwed firmly in opposition to each other, and filled in by pitch from the upper or open hatch. It was apparent that if a ship was air-tight the water could only enter so long as the air was compressible; and by inverting the pump boxes, and rendering them air-pumps the leak would not only be stopped, but by the continual action of the air it would be expelled by the very orifice by which it entered; therefore the customary and continued labour and power of the crew would not be required to such an extent, if at all, when once the necessary quantity of air had been forced in. So far back as 1823-4, he had introduced this principle at Bermuda; and, on a late occasion, when he was consulted by Mr. Marryat, chairman of the London Dock Company, as to the value of one of those lifting caissons, he proved to the parties that, by the aid of a glass tube, about 3 ft. long and half an inch bore, he could by his lungs, even at his age, effect the very same displacement which they had obtained by machinery. He then proceeded to explain, in detail, how, by pursuing his mode of construction, the vessel would not only become very much less liable to injury by the ram advocates, but, if carefully and scientifically fitted she might be over-run by an adversary, come up on the other side, and perhaps return the compliment. The gallant Admiral concluded by making a few observations on moveable armour, which might be adapted as a further protection to those vessels, which could be carried to a foreign station or long voyage in the hold, and, when war was declared, might be put on as occasion demanded.

ON TARGETS FOR GUNNERY EXPERIMENTS.

Captain Douglas Galton read a Paper on this subject. It stated that the earlier experiments made on iron plates showed that 4½ inch plates at least were necessary to resist shot. This thickness of iron still left the plate liable to be hurt or fractured and knocked off even when not directly penetrated, and the extent to which it would thus suffer would, to some extent be regulated by the backing. The plan suggested in the "Warrior" target was simply that suggested by the idea of bolting a plate of iron to the sides of a wooden ship. The iron skin of the "Warrior" is covered with two layers of teak planking, each 9 in. in thickness, the one horizontal the other vertical, and outside of those is the armour-plate, 4½ in. thick, secured by bolts screwed-up with nuts inside of the ship. The wood-backing was to prevent the injuries sustained by the plate from being communicated immediately to the ship, but it afforded no effectual support to the plate itself. The next class of targets to which Captain Dalton referred were those having a rigid backing, being wholly composed of iron. Mr. Hawkshaw had proposed one consisting of a thick front plate backed by a series of thin plates secured by rivets. Mr. Scott Russell had proposed a most ingenious arrangement by which the strong front plates were kept in position without any rivets or bolt heads being exposed. Others had also been tried. The trials of these targets had demonstrated that a perfectly rigid backing was not desirable. The arrangement required for the armour-plating of a ship, was a strong front plate, on which deflection under blows should be prevented, but which should have some cushion behind to prevent the full concussion of the blow being communicated to the side of the ship. The target to which he (Capt. Galton) wished to draw attention, was constructed on these principles, and was shown in the diagram. It had the metal placed in a form suited to resistance, and it had a cushion of wood interposed between the target and the ship. This target was invented by Mr. Chalmers. It consists of—1, a thick front plate, as the top flange of a beam; 2, of ribs to support it, as the web of a beam; and 3, of a plate of iron to hold up the ribs, as the bottom flange of a beam, and the ribs are supported laterally by timber to prevent their lateral deflection. Between this and the side of the ship a cushion of timber is interposed. This target underwent a similar trial to the "Warrior" target, and the result showed that it was the best target that had been tried, though it was not intended to suggest that it was perfect. It was, however, in this direction that experiments for devising the best form of armour-plating should be made.

RIFLED ORDNANCE.

Mr. Geo. Richards read a Paper on this subject, which was illustrated by diagrams representing the square-bore gun of which the Paper treated. He stated that the purpose of the square-bore gun was to give greater initial velocity to projectiles than was attainable by any plan yet proposed, inasmuch as the area of the square bore was at least 20 per cent. more than that of the circular bore containing a shot of the same diameter, thereby exposing, by using a wad or sabot, a greater surface to the impact of the ignited powder. The invention embraced two principles:—In the first place, the square bore gave at least 20 per cent. more initial velocity than the round bore of the same diameter; and secondly, the plan of obtaining increased velocity to any extent was by means of projections or rails in the interior of the bore on which the shot runs or slides, there being the necessary amount of twist to give the shot the rifled motion. In both cases the sabots would be used to act as air-tight pistons, but might be dispensed with by using wedge-like shoulders on the periphery of the shot to fill up the angular spaces of the bore, and also to give the shot the piston-like qualities sought to be obtained. This principle of presenting an increased surface to the propelling power of the gas was considered to admit of an extra power in aid of velocity of 15 tons to the square inch. Those forms of bore would admit of shot whose transverse section might be either square, hexagonal, octagonal, cylindrical, or other geometrical or polygonal forms of areas. In addition, Mr. Richards showed a method of loading heavy ordnance (applicable to sea service) by means of a loading-rod. The method of loading the gun was by means of a loading-rod passing through a perforation in the breech of the gun, and thence to the muzzle. The cartridge used was also made with a perforation through which the loading-rod passes. The loading-rod was quickly attached to the base of the projectile at the muzzle of the gun. Both rod and charge were quickly drawn into the chamber of the piece, disconnected in readiness for loading, and the breech was then closed by a small apparatus, such as a revolving disc.

ON THE DECORTICATION OF CEREALS.

Mr. Robert Davidson, C.E., read a Paper on this subject. The Paper described a plan by which the outside gummy and resinous pellicle, the inner thinner skin, and beneath it a third envelope, formed of impalpable dust, were removed from the grain. These three envelopes form the bran. The advantages obtained by their removal was 10 per cent. increase in quantity of flour (at least upon wheat), and 12 to 15 per cent. upon barley and oats; and, at the same time, a finer colour and a better taste. It was contended that decortication was advantageous in a hygienic point of view.

ON IMPROVEMENTS IN MACHINERY, AND APPARATUS FOR CLEANSING AND PURIFYING CASKS.

A Paper on this subject was also read by Mr. Davidson. The machine, a model of which was exhibited upon the table, consisted of a double frame, suited to the form and size of each cask, revolving one within the other in such a compound manner as to cause a chain of peculiar construction, assisted by hot water, to traverse completely every portion of the cask, and so effectually remove all adhering matter. Eight casks can be washed at once, as shown by the model.

The *Pays* states that the two iron-clad ships building by Mr. Laird at Birkenhead are not constructed for the French Government, but that they have been ordered by the Government of Egypt, as their names indicate.

FELL'S LOCOMOTIVES.

FIG. 2.

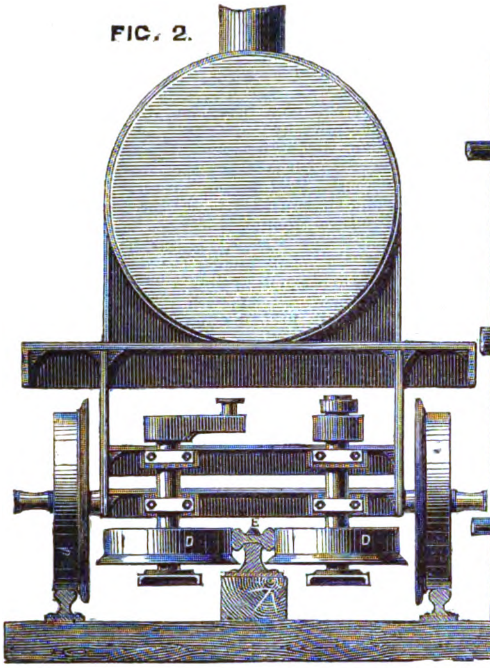


FIG. 1.

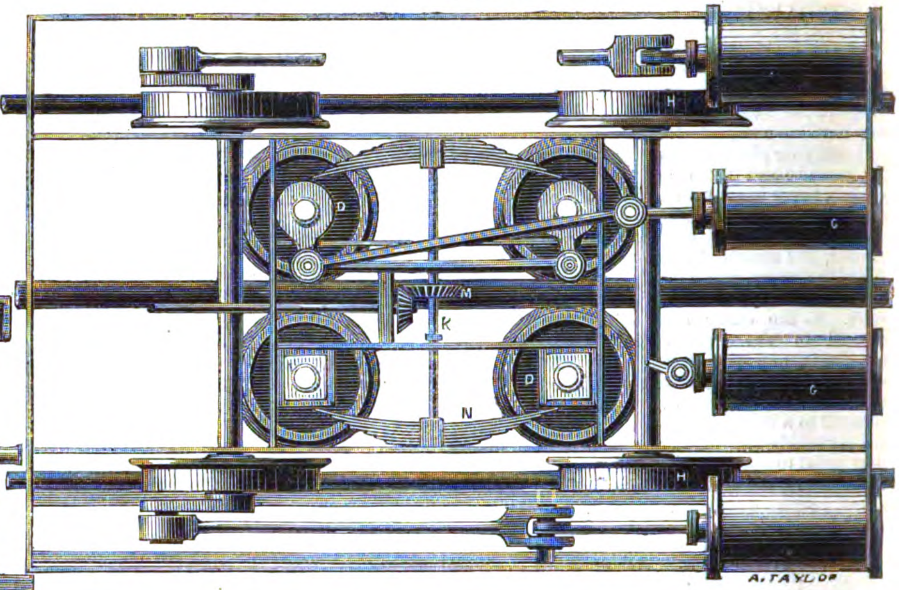


WORKING RAILWAY ENGINES AND CARRIAGES ON STEEP INCLINES.

THE following inventions for improvements in working railway carriages and engines on steep inclines have just been patented by Mr. John Barraclough Fell, engineer, of Sparkbridge, Lancashire. The object of these improvements is to enable locomotive engines and carriages to travel up and down steep inclines with facility and security. For this purpose the patentee applies to the engines and carriages, wheels in pairs or sets of two or more, so arranged as to work on either side of a central rail, and to press and hold on such rail with a pressure and holding adapted to the circumstances of each case. In travelling up inclines the wheels of each pair or set are worked by the engine at a speed and with a pressure on each side of the central rail according to the load and the rate at which the engine has to travel, and the adhesion necessary for taking the load up the incline. In descending the inclines these pairs of wheels on the engine and carriages are employed as brakes, with an adhesion adapted to the load. These pairs of wheels also hold on either side of the central rail, in such manner as to afford a great amount of security against the wheels of the engines or carriages jumping and getting off the lines of rails on which they are travelling.

In the accompanying drawings, figs. 1 and 2 represent the plan and end elevation of a locomotive engine, which, independently of the ordinary bearing and driving wheels, is furnished with two or more horizontal wheels D, D, pressing against the central rail E. The wheels D, D, are driven by two additional steam cylinders G, G, as shown by the plan, fig. 1. A transverse shaft K is provided with a right and left-handed screw, which being acted upon by the wheels M, M, draws together the springs N, N, by means of which the horizontal wheels are made to press upon the central rail, and so obtain the amount of adhesion required. Horizontal wheels may be also attached to the carriages and waggons, and constitute so many brakes. For the descent of steep inclines the horizontal wheels of the engines may be reversed, in order to check the speed, or to secure the immediate stoppage of the train. The additional adhesion wheels, shown in figs. 1 and 2 in a horizontal position, may, if preferred, be placed at an angle of 45 deg., or less, and may have their tyres cylindrical or grooved. In order to avoid friction in a vertical direction between the wheels and the central rail resulting from the movement of the engine on the springs which support it, these wheels may be so fixed on the axles as to allow them whatever vertical play may be needful. The pressure of the horizontal adhesion wheels upon the rail on which they work may be produced by means of a steam cylinder, or by water pressure, or by the use of springs of any convenient form.

The steam cylinders employed for rotating the horizontal adhesion wheels may be placed in the position shown in fig. 1, or fore and aft in the centre of the engine; or instead of being so placed, they may be placed vertically together at either end of the engine, or in the same horizontal plane, and be so inclined as to work on the same axle. In the first illustration the cylinders cannot be conveniently coupled without the use of toothed wheels, which are dispensed with by different arrangements.

It will be readily understood by all who are conversant with the construction of locomotive engines and the working of railways, that the disposition as well as the proportions and arrangement of the parts must necessarily be varied in each case to suit a particular type of engine; and it will be also understood that the horizontal adhesion wheels can be applied to the tender of the locomotive engine, and be worked by means of independent cylinders contained within the engine framing, or applied within or under the tender and receiving steam from the main boiler. In like manner, when it is deemed advisable, horizontal guide or adhesion wheels may also be applied to the under side of the brake carriage or waggon, or any other carriage of a train, and be worked or rotated by means of steam or other power, either from the cylinders contained within the locomotive framing or the tender, or connected to the carriage itself; and such means of rotating the adhesion wheels may receive the power from the main boiler of the locomotive engine by means of steam pipes communicating therewith; or motion from the horizontal adhesion wheels on the engine may be communicated to similar horizontal wheels fitted to the tender, or to the following carriage or carriages, by means of coupling rods, the cranks of the engine and carriage being coupled by double rods and an intermediate crank as a transmitter, and also as a means of compensation whilst passing round curves. The pressure of steam in the boiler may also be employed for producing the requisite amount of adhesion between the horizontal wheels and the central rail, or it may be applied by hand.

MELLOR AND WHALEY'S IMPROVEMENTS IN STEAM-HAMMERS.

THE following improvements in steam-hammers have been recently patented by Messrs. William Mellor, of Manchester, and William Whaley, of Rainow, in the county of Chester. The invention consists in communicating motion to the slide valves of steam-hammers, and other engines driven by steam, by means of a screw which passes through a nut formed in the piston, so that as the piston moves up and down or to and fro in the cylinder, the screw is turned round in opposite directions. This screw is made of the same piece, or attached to another screw acting on a nut connected to the lever to which the valve spindle is jointed; by this means the slide valve is moved to and fro to open and close the steam ports in the valve box. Another part of the invention consists in connecting the valve lever to a rod acted upon by levers and rods, for the purpose of varying the position of the fulcrum of the lever, so as to increase or diminish the length and force of the stroke.

The invention admits of modification, by placing the screws to one side of the piston rod; in this case one of the screw nuts is connected to a projection on the hammer-head, and the other is connected to the valve spindle.

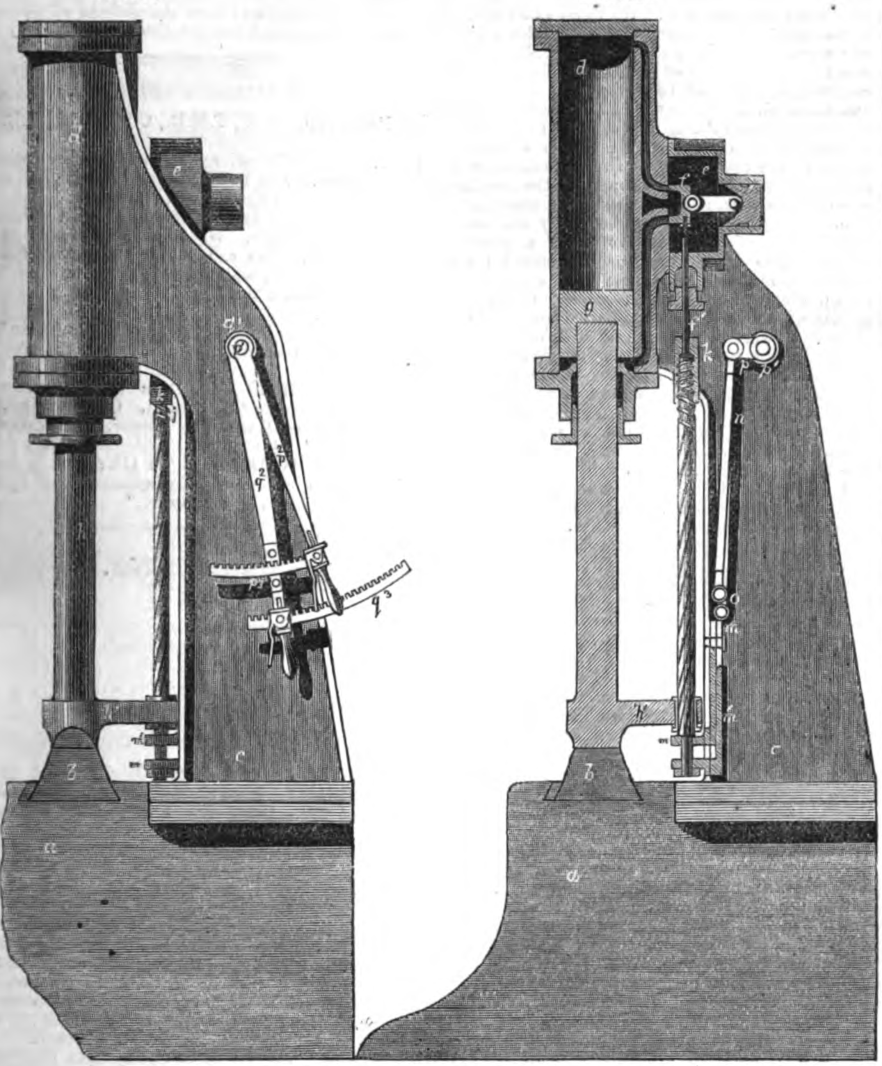
The patentees state that they describe these improvements as applied to a steam-hammer, but they are applicable to all or most engines driven by steam.

Fig. 1 of the accompanying drawings is an elevation of one form of steam-hammer, constructed according to this invention, and fig. 2 a section of the same. a is the anvil block and foundation plate; b, the anvil; c, the standard, cast of the same piece as the cylinder d; e is the steam chest or valve box; and f, the valve; g is the piston; and h, the piston rod, the lower part of which forms the hammer-head.

The screws i and j are placed to one side of the piston rod h, to which is connected the projection h^1 containing the nut working in the screw i. The nut k of the screw j is fixed to the spindle f_1 of the valve f; this nut passes through a bush in the standard c, and is provided with a key to prevent it turning round, but to allow it to move up and down. The vertical position of the screws i and j, and consequently the relative position of the valve f to the ports in the cylinder, can be regulated by the handle levers p^2 and q^2, which act respectively on the slides m, m^1; these sliders

MELLOR AND WHALEY'S IMPROVEMENTS IN STEAM HAMMERS.

FIG. 1. FIG. 2.



have projections at their lower extremities through which the end of the screw i passes.

The mode of operation is as follows:—When the piston g rises in the cylinder d, the nut in the projection h^1 of the piston rod h causes the screw i to rotate, thereby turning the screw j round in the proper direction for elevating the nut k and valve f, as described.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

On the night of Saturday, the 5th inst., the monthly meeting of members of the above-named society took place at 35, St. Swithin's-lane, City —Mr. Joseph Newton, President, in the chair. After the minutes of the preceeding meeting had been read, the auditors for the half-year just expired presented their report, which showed that, in a numerical and financial sense, the association was in a prosperous condition.

The Chairman next called upon Mr. Gettliffe to read his promised Paper on "an Apparatus for the Prevention of Steam Boiler Explosions and Railway Accidents." That gentleman, after some preliminary observations, proceeded to say that the apparatus in question was the invention of M. Auguste Achard, C.E., of Paris, and that it was known in France under the title of the "Embrayage Electrique." It was calculated to maintain a constant level in steam boilers by automatic means, and without the assistance or supervision of the engineman. This regulator, as it might be termed, consisted of a ratchet wheel of peculiar construction, and which was keyed upon a spindle turning freely in its bearings Right and left of the wheel were mounted, loosely on the spindle, two wrought-iron levers of about 20 in. each in length, and connected together by cross-pieces. A two-armed "click," supported by the levers, turned freely round an axis. The double click acted freely upon the ratchet wheel, which was furnished with two sets of teeth, turned in opposite directions to each other, and separated by a blank space. The click was fitted with a tail-piece in the form of a fork, the two prongs of which were braced together by a cross rod. In the fork was mounted an "armature," which was provided with an opening through which passed the cross-piece. The armature was made of brass, and to it was attached a plate of soft iron fitted in so as to be flush with the surface of the armature. Opposite to this latter was placed a horizontal electro-magnet, the poles of which abutted against the armature in such a way as that it (the armature) could only slide against the poles without coming into immediate contact therewith. The part played by the armature was merely to act as a weight on the levers supporting the fork; for it would be understood that when the electric current was in circulation, the armature would be suspended by its adherence to the electro-magnet, and thus relieve the fork of its weight. The suspension of the current, on the contrary, would cause it to drop on the cross-piece connecting the levers, and thus alter the gravity of the fork. It was these alternations of the weight on the tail-piece of the levers which caused the fork to act upon the upper or lower set of teeth on the ratchet wheel; or, in other words, to open or shut the feed-cock of the boiler. It was necessary that the fork should have continual motion—a kind of pump-handle movement, indeed—which could be effected by a simple contivance (a small eccentric, for instance, attached to a running shaft on the general machinery). The effect would be that the compound ratchet wheel would be acted upon and moved in one direction when the boiler required feeding, and in the other when it had been fed sufficiently. If all were going on well, the click would simply move over the blank portion of the wheel, and communicate no motion whatever to it. Proceeding now to the general action of the contrivance, the reader proceeded to state that when the current was broken off from the electro-magnet, the weight of the armature operating upon the cross-piece would press down the tail-piece of the levers carrying the click, which latter would rise and act with its lower arm upon the ratchet wheel. The consequence would be, that the wheel would turn from left to right to the extent of one tooth, or about half an inch, at each oscillation of the levers, until the blank space presented itself and stopped further movement. This would be at a point when the wheel had made one-fourth of a revolution. On the other hand, when the current was in circulation, the armature, in sliding against the poles of the electro-magnet, would bring the plate of soft iron into contact with the poles, which would then hold it firmly, and prevent the armature descending with the click during the downward oscillation of the levers. The tail-piece would thus be relieved, and not have to support any weight while the levers rocked in the opposite direction. It would follow that the upper arm would then act upon the wheel, and cause it to turn the reverse way, *i.e.*, from right to left. It would thus become evident that the two-armed click would act on the ratchet wheel, and cause it to move in opposite directions, whether the electric current were traversing the electro-magnet or not. "Now," said the reader, "the characteristic feature of the electric regulating apparatus is arrived at." The rising or falling of the float in the boilers of stationary or land engines controls the electric current, and causes it to circulate or be interrupted at the proper times. This result is obtained directly by the wires which proceed from the pile or battery being made to pass first to the float instead of being connected immediately to the electro-magnet. The float itself was connected by a rod with an index, on the lever of which was mounted a piece of wood faced on one side with a brass plate. On another piece of wood, in the form of a rocking lever, and moving on an axis, was a second plate of brass. The electric wire from one of the poles of the battery was fixed to the first-named plate, and the other end of the wire, after traversing the electro-magnet, was attached to the other pole of the battery. In order that the current might circulate, it was indispensable that both plates should meet, and from the peculiar arrangement of the two metallic plates, they would always be in contact when the index was at zero (the normal feeding point) or above it, but the contact ceased as soon as the index fell below zero. Let it be supposed that the feed-cock of the force-pump, or other contrivance for supplying water to the boiler, was connected to the spindle of the ratchet wheel: it would follow that the cock must partake of the movement of the wheel, and that it will make a quarter of a turn in one direction when the electric current circulated, and a quarter of a turn in the other when the current was interrupted; thus the automaton regulator, which was sensitive to the smallest alteration in the water level of the boiler, was perpetually and inevitably maintaining it at a constant height, and thus one great source of danger was obviated. As an extra security, however, against accident by explosion, a minor contrivance was affixed to the same apparatus, and which owed its action to similar principles. On the side of one of the levers was fastened a cap with a gudgeon in its centre. An armature resembling that already de[illegible] was carried

by this cap and rested on the gudgeon. In connection with the second armature was placed an electro-magnet, against which it was made to slide and press constantly upon the poles. It was still the index of the water gauge, which induced the circulation or effected the interruption of the electric current; and the same electric pile or battery, composed of a single element, or Daniel's pair, sufficed to put in motion the two electro-magnets. The electric wire which proceeded from one of the poles of the battery, and was affixed to the brass plate on the lever of the index, served for the two electro-magnets also. The returning wire corresponding with that about to be described, however, was fixed to a third brass plate, and, after traversing the electro-magnet was attached to the second pole of the battery. The last-mentioned plate was arranged in such a manner as to establish a metallic contact, which permitted the electric current to pass, notwithstanding the variation in the level of the water to the extent of an inch above or below its proper line. If the variation exceeded these limits, the current would be forcibly broken. When the electric current was in circulation—that is to say, when the lever was between the limits of variation named—the armature would be suspended by the adhesion of the second electro-magnet; but if the level rose or fell beyond those points, the armature, from the current being broken, must fall. In either case, a small tappet fixed to the armature below the gudgeon touches an alarm lever and thus rings a bell. This arrangement was also serviceable in other respects. The alarm bell rings when the feed-pump is out of order; when the electric pile ceases to act; if the stoker neglects the fire; or if steam is generated too rapidly. The reader proceeded to point out the application of the "Embrayage Electrique" to the prevention of railway accidents by connecting it with brakes upon the wheels of the engines and carriages, and certainly gave some very practical illustrations of its value and efficacy in this respect. In France it is extensively used, and testimonials in its favour from many eminent scientific men were submitted to the Associated Foreman Engineers on Saturday night. Mr. Gettliffe, moreover, exhibited the apparatus itself to his audience, and thus gave them a further opportunity of judging of its characteristics.

On the conclusion of the Paper, a short discussion arose; and in this Messrs. M. Jones, Ives, Briggs, and Bragg took part. In reply to questions put by these gentlemen, the reader stated that at the works of Mr. Cater, engineer, &c., Grove, Southwark, an apparatus of the kind he had attempted to describe might be seen in daily action, as also at Messrs. Simpson's, in Little Britain, City. The office of M. Achard was at 1, Little Carter-lane, Sr. Paul's.

The Chairman then proposed a vote of thanks to Mr. Gettliffe for the able way in which he had explained an ingenious apparatus of great interest to the members of the Society of Foremen Engineers. He had, from what he had heard and seen on that evening, formed a good opinion of the contrivance, and he should take an early opportunity of witnessing its action. The time was approaching when Electricity would become a universal handmaiden to applied science, and mechanical men would do well to study closely its phenomena. M. Achard had, in the production of his "Embrayage Electrique"—in substitution for the title of which an English one must be found as expressive—demonstrated his great talent, and in Mr. Gettliffe he had found an excellent expositor.—The vote of thanks having passed, the meeting shortly after separated.

PISTON SPEEDS OF BEAM ENGINES.

At one period of the science of steam engineering it was the practice to fix the limit of the speed of the piston at so many feet per minute; and from this and the other data usually taken into account—as the area of the piston, pressure of steam, &c.—the horse-power of the engine was calculated. If we are not in error, 250 ft. has been set down as a standard speed for pistons; but modern engineers prefer to drive their pistons as fast as they can with safety, and to disregard rules which experience proves the uselessness of. We have, as a result, the performance of the engine of the "Golden City" (a new steamer belonging to the Pacific Mail Steamship Company). It is of the beam variety, the beam weighing upwards of 18 tons. This engine has a piston 105 in. in diameter by 12 ft. stroke, and upon a recent engineers' trial trip, achieved the remarkable speed of 420 ft., or 47½ double strokes per minute. We have no doubt that the engine will be able to add materially to this speed, as the machinery was entirely new, it being merely an experimental trip. This is not an isolated case, by any means. The "City of Buffalo," formerly a passenger steamer upon Lake Erie, now dismantled for the want of trade, had an engine with a cylinder of 76 in. diameter and 12 ft. stroke, which drove paddle-wheels 34 ft. in diameter, whose floats had 31 in. face, were 11 ft. long, and had from 36 in. to 40 in. dip—19½ revolutions, or 39 single strokes per minute. By a severe exercise of mathematical knowledge, we ascertain this to be a piston speed of 468 ft. per minute. We remember these facts and figures very well, as at that time we were pretty much occupied in looking after the engine aforesaid. The beam weighed nearly 16 tons, and was stopped and started 39 times in a minute, working with great ease and certainty. The beam of a beam engine appears to some to be an insuperable obstacle to the general adoption of the class of engines to which it belongs; and its weight, momentum, velocity, &c., are charged heavily to its demerit. These theories, we fancy, are disturbed by the actual facts in the case, which are, that the beam is so poised and balanced on its centre, that the supposed shock of changing its line of motion is utterly neutralized; and as for the weight, that is supported by the framing, and is no more against the power exerted by the piston than the smoke stack. A beam, weighing 15 tons, or 18 tons, can be moved through any portion of its arc of vibration, by the strength of a man; providing, of course, that the binders of the pillow blocks are not screwed up, and that the journals sit fairly on the brass. The above-cited cases of the speed of beam-engine pistons are all distanced by the extraordinary performance of the "C. Vanderbilt," a Sound steamer, in her race, June, 1847. This engine is of 65 in. cylinder and 12 ft. stroke, and on the occasion mentioned, attained to 540 ft., or 22½ double strokes per minute. It is not at all uncommon or extraordinary to obtain a piston speed in beam engines of 400 ft. per minute, in this country; but the performance of the "Golden City," we think, is the best on record, considering the size of the cylinder.

Since writing the above, we have ascertained that all the facts just mentioned are below the mark. The "Mississipi," a large paddle steamer, having an 81 in. cylinder and 12 ft. stroke, has made 24 revolutions per minute, the wheels having 36 in. dip, and attaining a piston speed of 576 ft. per minute. The "Metropolis," a large Sound steamer, having a cylinder of 105 in. diameter and 12 ft. stroke, has made 20 revolutions per minute, and we think a higher number. The working beam on the "Mississippi" weighs 14 tons; that on the "Metropolis" about 16 tons. The engine of the "New World," a side-wheel steamboat 420 ft. long, on the Hudson river, having a 76 in. cylinder, and 15 ft. stroke, has made 20 revolutions per minute or 40 single strokes. The "Richard Stockton," however, has outstripped the whole fleet, and, we think, attained the highest piston speed for an engine of this class ever made in the world. We do not know the exact dimensions of the cylinder, but have been told it is between 50 and 60 in., with 10 ft. stroke. The "Stockton" has feathering wheels, and makes 32 revolutions, or 64 single strokes per minute; and has done this duty for years, having been built by Robert L. Stevens, for the express object of testing the speed at which a piston could safely travel. This is the highest speed within our knowledge ever attained by a piston in an engine of similar size; if any other instances come to mind we shall place them on record. It would be difficult to point out any other class of marine engine of the same size as that in the "Golden City," which could achieve 17½ turns a minute, and keep it up as a regular duty. The standard of 250 ft. per minute will have to be changed, and made to suit modern pistons, as the engines themselves stubbornly refuse to be controlled by any such snail-like movement.

[We give the above extract from the *Scientific American* as an instance of the high speeds which pistons may attain under the most unfavourable conditions. From the dictum of the writer in favour of the beam arrangement we altogether dissent; the rapid increase in the number of direct-acting engines employed in Great Britain proving conclusively that the defects of the beam are not theoretical but practical.—ED. M. M.]

TO CORRESPONDENTS.

RECEIVED.—E.X., T.M.R., C.W., A.N., T.B. and Co., C.K.

T. D. P.—We believe the annual subscription is one guinea. You had better write to the secretary. If you direct to Kew it will reach him.

H. M.—Many descriptions have been published from time to time. We know of none so full as you require. You can get all the Patent Specifications, however, which deal with the subject, from the Patent Office by addressing a line to Mr. Bennet Woodcroft.

R. B.—Patented long ago by Mr. Train, and described in the MECHANICS' MAGAZINE for Feb. 22, 1861.

A BLACKSMITH.—Ede, "On the Management of Steel." Tweedie, 337, Strand. One Shilling.

ERRATA. — Rankine's Paper, "MECHANICS' MAGAZINE," 28th August, 1863—page 607, col. 2, line 41, for "QOA," read "2 OA;" col. 3, lines 9 and 10 from bottom—for "displacement of speed," read "displacement and speed."

HIGH SPEED IN, AND ARMAMENT OF, OUR NAVY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Your Paper upon "High Speed in the Navy" cannot fail to arrest the attention and engage the serious thoughts of all who are interested in the well-being of England.

That England's exalted position has been attained by, and depends to a great extent upon, her undisturbed commerce, is generally admitted—to her maritime strength these conditions are mainly due.

If, therefore, England should ever again be involved in war with a naval power, the efforts of her foe would be bent upon the capture, or extermination, of her mercantile marine. It behoves her, then, to provide, while at peace, every means for its protection; such means being suited to meet the modes of warfare likely to be adopted.

No course can be more futile than that which is disregardful of the changes that are being induced by destructive appliances, little dreamt of in the days of Nelson, when large ships and heavy ordnance were looked to, and relied upon, as the bulwark. In the present state, however, of the art of war, large ships and heavy ordnance will be found useless—worse than useless—by reason that monster vessels will, upon the ocean, need protection, rather than be enabled to afford it. The much-vexed, but little understood problem of the torpedo, or submarine explosive shell, is in the course of solution on the other side of the Atlantic. It will ere long be, in all probability, found that such engine of destruction is very much more formidable in "blue water" than in rivers. Though the *active* mode of the employment of the arm in question, is that which would be resorted to by vessels adapted to its service, yet in a *passive* form only it would be an obstacle to the movement of attacking vessels that would prove, if not completely destructive, so damaging, at an rate, as to compel them to remain stationary.

Shell vessels need only to be lightly armed with cannon; one gun, or two guns at most, of long and accurate range, but of small weight, to bring to an unarmed or merchandise vessel; using the principal arm, the submarine shell only, when necessary. In such arrangement, there is nothing detrimental to speed—the conditions admit o[illegible] build to embrace a light draft of water, and [illegible] tonnage to carry comparatively a large suppl[illegible] fuel. These vessels may be so constructed a[illegible] endure any amount of rough weather without [illegible] of foundering—under a condition when [illegible] could not be safely cast loose, much less u[illegible] any degree of precision, by reason of ther[illegible] too much sea on, they would be most for[illegible] especially so, in the darkness of night. B[illegible] statements have been often expressed; [illegible] not be repeated. For the proof of thei[illegible]

they must abide their time, like other important truths that have been for long periods suppressed.

This is, in truth, a subject for contemplation.

I am, &c.,

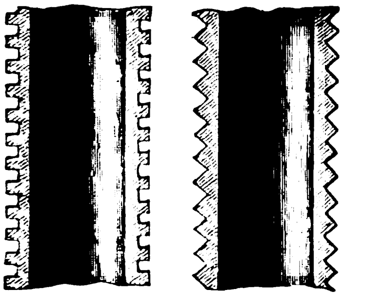
JN. HARVEY, Capt. R.N.

5, Keynsham-parade, Cheltenham,
Sept. 7, 1863.

LOCOMOTIVE IMPROVEMENT.

SIR,—Much has already been done to increase the heating surface of steam boilers, but I think a further improvement may be effected by increasing the *surface in contact with the water*, without a further increase of the absorbent surface.

It is pretty generally known that flanges cast on air warming apparatus, as applied by the London Warming and Ventilating Company, greatly increase the effect of such apparatus, the cause being that a greater surface of heated metal is in contact with the air. I think, therefore, that if the metallic surface of tubes, flues, &c., of boilers, in contact with the water, be increased in area, an increase of evaporation will ensue. This may be effected in several ways, varying with the form of boiler; but, in the case of locomotive boilers, the two modes shown in the accompanying sectional diagrams might be found most simple and effective.



Neither the thickness or the weight of the tubes need be much, if at all, increased.

I am, &c.,

T. MOY.

Clifford's-inn, Sept. 5, 1863.

FOG NAVIGATION.

SIR,—If behind the fog-whistle of steamers were placed a revolving reflector—said reflector being of the proper form to cover an approaching craft with the collected rays (sound waves)—would not the sound be intensified, and, moreover, the quicker attract attention from its being

INTERMITTENT?

San Francisco, July 30, 1863.

Miscellanea.

There are at present two distinct telegraphic lines being laid down to the extreme south-western coast of Ireland—one to Crookhaven by Mr. Reuter, and the other to Cape Clear by the Magnetic Company. As this part of Ireland is the nearest to America, intelligence from the other side of the Atlantic will be received in Europe earlier than would otherwise have been the case. Both lines are completed to within about 8 miles of Skibbereen.

Mr. M. Assman, a Prussian-Polish Jew, resident in Fawcett-street, Sunderland, has invented a clock which keeps time on what he claims to be a new principle of metallic motive power. The clock has neither weights, chains, springs, nor pendulum, and keeps time without the slightest noise or ticking. The principle of the clock is so simple that it will need little or no regulating or repairs, and the inventor believes it will surpass in time-keeping the most correct watches and chronometers now in use. Mr. Assman intends shortly to exhibit his clock.

On Saturday last the iron paddle steam-vessel "Normandy," built by Messrs. Ash, of Millwall, for the South Western Railway Company, and intended for the mail and passenger service between Southampton and the Channel Islands, left Blackwall with her commander, Captain Babot, and a numerous party on board, for a trial trip, to test her machinery and engines, which are manufactured by Mr. John Stewart, of Poplar. During the trip to the Nore her engines, which are 225 nominal horse-power, were worked up to eight times that amount, or 1,800-horse power, and a speed of 17 knots per hour was obtained. The cabins, &c., of the "Normandy" have been fitted-up and furnished in excellent style for the accommodation of 150 passengers, and she is capable of conveying 250 tons in addition. Her draught of water is 8 ft. 9 in. aft. and 8 ft. forward.

Sir W. Armstrong's alarmist views upon the speedy exhaustion of English coal are disputed by Mr. Nicholas Wood, the great coal-viewer in the North, and perhaps the highest practical authority in England upon coal-mine questions. In the Geological Section at the British Association meeting, he has stated his reasons for believing that our supplies of coal will last much longer than the 200 years allotted by Sir William, and he refuses to believe that American manufacturers will one day enjoy vastly superior advantages in this particular over those now possessed by Englishmen. Mr. Wood relies much upon the coal deposits under the sea, as to the extent of which we know little, but which he believes will one day yield large supplies.

The electric light has been adapted for surgical purposes. A great difficulty in many operations is the want of light, and by means of a small vacuum tube, bent into a helix or screw, a kind of luminous cylinder is formed, which may be introduced in very narrow cavities. Carburetted hydrogen, carbonic and hydrochloric acid are used in the vacuum tube to produce whiteness in the light.

A serious fire has broken out in the Wellington Pit, at Whitehaven, the property of the Earl of Lonsdale. The pit is one of the largest in the kingdom, and the accident will throw abont 700 men out of employment, besides affecting the coal supply to Dublin.

From Sir R. Murchison's address at the anniversary meeting of the Geological Society, it appears that Sir Roderick (the greatest living authority on such a subject) believes, first, that the eastern shores of Great Britain, where Cæsar landed, have not changed their relation to the sea-level since that period. Secondly, that it is proved, from finding remains and bones of the same species of extinct mammalia in the gravel of Britain and the Continent, that at a comparatively recent period our islands were united with France. Thirdly, we know from the skeletons of the great Irish elk, which are found in the bottom of the bogs in Ireland, and also in the Isle of Man and in Cheshire, that when that creature lived these three islands must have been united.

The Abbé Moigno exhibited and described before the British Association M. Soleil's tenebroscope for showing the invisibility of light. The instrument consists of a long tube, closed at one end, but with a short opening in the centre, in which is introduced a white ivory ball, capable of being placed and withdrawn at pleasure. The object of the instrument is to illustrate the principle that light is only the action of the illuminiferous medium by which bodies are made visible; and that neither the light itself or the the medium, is visible. On looking through the glass with the ball withdrawn no light is seen, but immediately on the ball being replaced it is distinctly seen at the end of the tube.

A meeting of the citizens of Exeter and noblemen and gentlemen of the county of Devon met at the Guildhall last week, the Mayor in the chair, and unanimously agreed to take active measures to invite the Royal Agricultural Society to hold its meeting in Exeter in 1865. £600 was subscribed.

The *Post* announces that the Government intend to detain the two steam-rams "El Tousson" and "El Mounassir," at Liverpool. Our contemporary says:—There is now, we believe, little doubt that, under the terms of the Foreign Enlistment Act, they are now to be detained by Government. The allegation against them is that they are fitted out for the purpose of carrying on hostilities against the United States. On the other hand, it is not contended that they were built by order of a French house for the late Pasha of Egypt, who gave the firm a commission for the coinage of a large sum of money in France, and for the construction of two steam-rams in England. The money was duly coined and received in Egypt. The vessels were in construction when the Pasha died, and his successor repudiated that part of the contract. What the French house intends to do with them is not known. The accusation is that they are destined for war with a friendly Power. They will consequently be detained, and a court of law will determine whether, under the terms of the Foreign Enlistment Act, the detention is legal, or whether the owners can recover them from the hands of the Government.

The meeting of the British Association at Newcastle has now terminated, and has fully justified the high anticipations that were formed respecting it. The society, urged by Mr. Tite, M.P., and the Mayor of Bath (Dr. Barrett), have resolved to hold its next meeting in Bath. Sir Charles Pressley will be the President for 1864. The following officers have also been appointed:—Vice-Presidents: Lord Portman, the Marquis of Bath, Wm. Tite, Esq., M.P., Arthur Way, Esq., M.P., William Sanders, Esq., F.G.S., Lord Nelson, and T. H. Dickinson, Esq. Local Secretaries: Charles Moon, Esq., C. C. Davis, Esq., and the Rev. W. W. Winwood. Treasurer: Thos. Gill, Esq. The meeting was fixed for September, but the day for its commencement will be a subject for future discussion.

It is claimed that the Ferris gun, a newly invented weapon, gave a speed of 2,200 ft. per second to its shot, as measured by the electrobalist at West Point. The gun was tried in the presence of numerous officers of high standing in the army. The highest velocity ever obtained before was with a Parrott gun, the speed of the projectiles from which was 1,800 ft. per second. The Ferris gun obtained its high velocity from the quantity of powder burned in it, which is, in a 14-inch bore, 24 ounces, while the shot weighs 40 ounces—rather more than half the weight of the shot. At this rate the 100-pounder would require 60 pounds of powder, and the 200-pounder nearly 100 pounds—a fearful charge, certainly.

Horatio Ames, of Falls Village, Conn., proposes to make for the American Government fifty 300 lb. rifled cannon, to carry a 100 lb. charge of powder; price of the weapon 1 dol. per pound. The guns are intended to be nearly 10 in. bore, and weigh 30,000 lb. a-piece. They are intended to stand 1,000 rounds without bursting. We presume there are a great many forges willing to make such guns on similar terms.

The *New York Times*, in speaking of the attack on Fort Sumter, says:—An ingenious device of the rebels for blowing-up the shipping in Lighthouse Creek was recently discovered. It consisted of three metallic cases, of oval shape, fastened together by a strong cord. These cases are filled with powder, and upon the sides which float uppermost are delicately arranged hammers, with which a percussion-cap, hidden in a coating of gutta-percha, is to be exploded. These hammers stand out from the water at an angle of 45 degrees, so that when the cord shall have caught upon some cable, and the torpedoes shall have swung against the vessel's side, an explosion is inevitable. To General Vodges belongs the credit of bringing to light this infernal invention. With his sharp eye he discovered the mysterious contrivance floating on the descending tide, and at his instance a party of sailors was despatched by Captain Bacon, of the gunboat Commodore Macdonald, to pick it up. It was lucky for the little transport "Nantasket" that the torpedo was rescued from the water as it was, for in a moment more it would have been thumping under her bows.

The Act passed on the day of the prorogation to regulate the exercise of powers under special Acts for the construction and maintenance of telegraphs has been printed. It contains as many as 53 sections. Before a company proceeds to place a telegraph over, along, or across a street, not being a street in the metropolis or in a city, or a public road, or to place posts, they are to publish a notice that they have got the consent of the body having the control of the street, and leave notice at the dwelling-houses, and are not to place the telegraph until after 21 days' notice, during which time objections can be made to the Board of Trade. If any person in the employ of a company wilfully or negligently omits or delays to transmit or deliver any message, or by any wilful or negligent act or omission prevents or delays the transmission or delivery of any message, or for improperly divulging the purpose of any message, he may for every such offence be liable to a penalty not exceeding £20. All messages on Her Majesty's service are to have priority, and on the request of the Board of Trade a telegraph is by a company to be placed for the exclusive use of Her Majesty. The act further provides that in case of an emergency telegraphs may be taken possession of for Her Majesty's service by a warrant from the Secretary of State. The warrant is only to be in force one week, but successive warrants may be issued. The Treasury in such case is to pay the company for the loss sustained. A company may bepr oceeded against by the law officers of the Crown on a certificate from the Board of Trade that any provision of the Act has not been complied with or that compliance would be for the public advantage.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c.—*none*.
BOILERS AND FURNACES, 291, 304.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 309.
SHIPS AND BOATS, including their fittings, 299, 319, 334, 339, 341.
CULTIVATION OF THE SOIL, including agricultural implements and machines—*none*.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 310.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 294, 300, 301, 302, 303, 304, 327, 328, 337, 344.
BUILDINGS AND BUILDING MATERIALS, 293, 317, 318, 322, 347.
LIGHTING, HEATING, AND VENTILATING, 298, 307, 308, 315, 335, 338, 351.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 311, 312, 316, 325, 329, 336, 340, 345, 346, 349, 350.
METALS, including apparatus for their manufacture, 292, 296, 313, 342.
CHEMISTRY AND PHOTOGRAPHY, 343, 348.
ELECTRICAL APPARATUS—*none*.
WARFARE, 305, 321, 331, 332.
LETTER-PRESS PRINTING—*none*.
MISCELLANEOUS, 290, 295, 297, 306, 314, 321, 323, 326, 330, 333.

290. W. A. LYTTLE. *Improvements connected with cigar and other tobacco smoking appliances.* Dated January 31, 1863.

This invention is carried out as follows:—1, The inventor prepares a conical or other-shaped tube of paper, tobacco-leaf, or other suitable substance, and fills it with a filtering material. Into one end of this tube he inserts the "butt" or mouth-end of the cigar, attaching it in that position by gumming or otherwise, securely binding it previously to its sale; or he prepares the filtering tube so as to be saleable and portable as a separate article attachable to the cigar by the person about to use it. In the latter case, the inner surface of the end of the tube intended to receive the cigar might be coated with adhesive matter, so that by wetting the end of the cigar it may adhere on insertion. 2, As a filtering material he uses charcoal powder, cotton, wool, flax, hemp, or any other suitable powdered or fibrous material, or simply a roll or strips of a suitable kind of cloth or coarse paper. These materials may be used separately or combined, and may, if desired, be impregnated with perfume, and with chemicals possessing affinity for the empyromatic impurities of the tobacco smoke. *Patent abandoned.*

291. E. B. WILSON. *Improvements in supplying air, gases, steam, or fluids, to iron and other furnaces, and to engines and vessels requiring such supply, and in the apparatus employed therein.* Dated January 31, 1863.

According to this invention it is proposed to effect the supplying of air, gases, steam, or fluids to furnaces, engines, and vessels of all kinds requiring such supply, by the aid of a steam or air jet, the apparatus employed being constructed on somewhat similar principles to the instrument known as "Giffard's injector," but is modified in the manner hereinafter described, so as to enable an accumulative pressure to be obtained. In the improved apparatus the jet-pipe—which may be of annular or other form—is enclosed within an air chamber, which is contracted in front of the nozzle, and provided, if desired, with a regulating plug or apparatus. A branch pipe—which may be in the form of an inverted syphon or otherwise shaped—leads from the side of the air-chamber to the air, gas, steam, or fluid to be injected. On passing a jet of steam or air through the jet-pipe, a supply of air, gas, steam, or fluid, as the case may be, will be drawn through the syphon or other branch pipe into the air-chamber, and injected thence at an accumulated pressure by the jet issuing from the jet-pipe. *Patent abandoned.*

292. F. G. GRICE. *Improvements in machinery for the manufacture of bolts, spikes, rivets, and screw blanks.* Dated February 2, 1863.

We cannot here give the details of this invention. *Patent completed.*

293. E. H. MASSEY. *Improved preparation or compositions for coating and colouring the walls, ceilings, and other parts of buildings.* Dated February 2, 1863.

These compositions are composed of the following ingredients:—Whiting, well-ground and sifted, 3lb.; gum arabic, $\frac{1}{4}$lb.; starch, $\frac{1}{4}$lb.; flour, $\frac{1}{4}$lb.; ground alum, 2 oz.; chloride of lime, $\frac{1}{2}$oz. These substances are well mixed together in a dry state; and in preparing the composition for use cold water is added in sufficient quantity to form a stiff paste, and then boiling water is added to reduce the mass to a proper consistency. *Patent abandoned.*

294. J. GIBSON. *Improvements in looms for weaving.* Dated February 2, 1863.

This invention relates to means of working or operating the healds or heddles in looms for weaving, and the object is to facilitate the changing or converting of "Lancashire" or plain looms into fancy looms. On the ordinary tappet shaft the inventor places a tappet of peculiar form, capable of being readily moved and fixed in position to act upon the ordinary treading levers, in substitution of the ordinary plain treading tappets. He also applies additional levers in connection with the treading levers, so formed and arranged that hooked rods, depending from the ordinary "lambs," which are attached to the healds or heddles take hold thereon. These hooked rods are brought into contact with one or both of the said levers by cards from jacquard or other indicating apparatus, as required, and are withdrawn and held out of contact therewith by springs or weights; or the rods may be brought into contact by the springs or weights, and removed by the indicating apparatus. *Patent abandoned.*

295. A. FORBES. *Improvements in means or apparatus for soldering together parts of vessels formed of tin or tinned plate.* Dated February 2, 1863.

This invention is carried out as follows:—The top and bottom parts, together with the cylindrical or side surfaces of vessels formed of tin or tinned plate, having been shaped to receive one or the other, the patentee, at the part to be united, applies the solder in a ring or other form, together with suitable flux; and then in place of a soldering iron he employs the heat from the flame of gas jets arranged in a ring or other form adapted to the figure of the part of the vessel for the time to be united, such ring or other form being supplied with gas through the stem thereof by a flexible or other suitable pipe from a suitable reservoir, and for the straight part he applies a burner adapted thereto. *Patent completed.*

296. W. C. BARNES. *Improved means or apparatus for shaping, rolling, or compressing metal.* Dated February 2, 1863.

This invention relates to a combination of means, the object of which is to reduce the amount of labour necessary in shaping, rolling, or compressing metal into various forms. For this purpose there is a series of plates or discs or sections of rolls, into each of which the figures or discs for producing the required article are formed or fixed, and such plates, discs, or sections are so arranged or applied upon the shafts or spindles that they not only become top and bottom dies, but partake of the form of a pair of rollers or rolls, that portion of each where their operation is not required being of a diameter suitably less in proportion to the figure of the article to be produced. These rolls or rotary dies are caused to work simultaneously at the same surface speed, and towards the position for holding the article or piece of metal to be operated upon. The bar or other form of metal to be operated upon is placed between the rolls to the extent desired, and whilst the smaller diameters of such rolls are opposite each other; then, so soon as the operating parts or dies come into operation, the action is to repel the bar whilst giving form to it, by pushing it back in their rotary course towards the workman or starting-point. The position of the metal to be operated upon is adjustable by stops, and the carriage or holder in which the metal or article is placed is composed of a compound slide; and on the revolution of the slides, as that part comes round for giving form, the squeezing or compression takes place, and the metal is formed into the figure of the operating parts, as a bayonet or other article, which, being forced back in its proper form, the machine is ready for the insertion of other metal to be similarly operated upon. *Patent completed.*

297. R. H. FRITH. *Improvements in the manufacture of paper.* Dated February 2, 1863.

This invention consists in the reduction of peat or turf bog into a pulp, which is then bleached by the application of chloride of lime, or by any other chemical bleaching process, and afterwards manufactured into paper in the ordinary manner. *Patent abandoned.*

298. E. B. WILSON. *Improvements in the manufacture of gas.* Dated February 2, 1863.

This invention consists in the manufacture of gas from oil, by placing in a suitable vessel containing the oil a coil of piping, pipe, or pipes through which the inventor passes hot water, air, or steam at such a temperature as shall generate gas from the oil contained therein, which vessel may be large enough to be but partially filled with oil, leaving the remaining space for gas; or a separate receiver with purifier may be connected. *Patent abandoned.*

299. W. CLARK. *Improvements in armour plated or other ships.* Dated February 2, 1863.

According to this invention, the patentee builds war ships having the main body or continuous part of the hull but little above the load line, say some 3 or 4 ft., or it may be only to the load line; so far the mould of the ship is much as in ordinary. From this level he carries up the hull of the ship in sections, say, in two sections or parts (for a ship 400 ft. in length) of about 100 ft. in length, the one part commencing, say, some 30 or 40 ft. from the stem, and the other about 20 ft. from the stern. These parts he builds up to the height necessary for a man, and sheaths or coats them entirely with armour plates. The fore part of these sections or parts he prefers of a buff bow shape, while the after parts may be of a semicircular or other form. The part of the lower body unoccupied by these sections or structures will be a kind of a deck which he forms and covers over with strong iron plates to give the necessary strength to the hull, and to resist the force of exploded shells, or the graze of shot, to which alone it would be subject being nearly or quite horizontal. In building these vessels he carries a light upper deck over the entire area of the ship, which deck is carried between the raised parts of the hull on girders stretched from the one to the other, and if necessary supported by pillars from the exposed plated deck below. He has mentioned the raised parts of the hull as being two in number, but three or other number may be adapted. In the arrangement before described he also carries up a small section immediately behind the stem, but which need not be covered with armour plates; it would serve as a communication to the forecastle, and as a support for the fore part of the upper deck; or the deck may terminate at the armour-protected part both fore and aft. Besides covering the raised parts of the hull with armour plates, say, to the required depth of 5 ft. below the water line and over the whole of the lower part of the hull rising above the water which may be to the extent of 2, 3, 4 or even 5 ft., it may be necessary that the main and full length part of the hull requires to be 5 ft. above the load line to give the ship the necessary boyancy or liveliness, but which may not be the case as the raised parts of the hull are intended to and will give great boyancy if depressed in the water by the pitching and rolling of the vessel, and may produce all the necessary buoyancy, even although the full length and low parts of the hull be only at a level with the water line; it may even be advisable to sink that part of the hull below the surface of the water by admitting water ballast or otherwise before going into action. In the latter case the armour plating might be dispensed with at the low parts of the hull, while if sunk by the admission of water ballast only to the level of the water line, a depth of 5 ft. of armour plating would be sufficient. *Patent completed.*

300. C. and G. L. SMITHIES. *Certain improvements in preparing and bleaching "Rheea" and other fibrous materials and fibres, which improvements are also applicable to bleaching yarns or piece goods.* Dated February 3, 1863.

The fibres or fibrous materials after having been properly cleansed and opened by scutching machinery are placed in trays, skips, or baskets made of galvanized iron wire, or other suitable material, and provided with handles to facilitate their being moved about and raised from or lowered into cisterns or vats by cranes or other suitable appliances. The trays or baskets with their contents are now immersed in soft cold water contained in vats or cisterns, having removable grids at the bottom to admit of the separation of any deposit or sedimentary matter, and the fibre is allowed to soak therein for a space of 24 hours, at the end of which time the water is to be withdrawn. The cisterns or vats are then refilled with clean soft water, which with the fibrous materials or fibres is maintained at a temperature of from 90 deg. to 100 deg. Fahr. for a space of 24 hours, by passing steam into the cistern or vats by means of any convenient apparatus connected therewith. The fibrous materials are then removed and passed between grooved or fluted rollers under a suitable pressure to express the water and various impurities dissolved by the foregoing treatment, and also to break and soften the fibre, and they are then treated with vegetable, animal, or mineral oils, if necessary, and replaced in trays or baskets constructed in the manner hereinbefore described, but provided in this case with partitions or divisions for keeping the fibres straight, and preventing matting; the baskets or trays are then placed in an air-tight chamber or vat having a removable grid or perforated false bottom. After the air has been exhausted by any ordinary means from the chamber or vat, the bleaching liquor—which consists of a solution of caustic soda or other caustic alkali—is admitted at the bottom and forced up through the fibrous materials until the said vat or chamber is filled, and the materials are to remain thus saturated for about 12 hours at a temperature of 120 deg. to 212 deg. Fahr., according to the nature of the fibrous materials acted upon, and the purpose for which they are intended. The air is then to be admitted into the vat or chamber, and the waste liquor drawn off, when the fibrous materials are subjected to the action of the solution of soap and soda, or caustic soda, or other alkali, until the colouring matter has been removed. *Patent completed.*

301. T. RAWORTH. *Improvements in looms for weaving ribbons, elastic webbing, and other narrow fabrics.* Dated February 3, 1863.

The patentee claims driving two or more shuttles or sets of shuttles by driving racks communicating motion by wheels or pinions mounted on concentric spindles or axes, in the manner and for the purposes described. *Patent completed.*

302. G. HOLCROFT. *Improvements in preparing cotton for the operations of spinning and weaving.* Dated February 3, 1863.

This invention consists in subjecting the lap of cotton produced by the blower, or the slivers produced on the carding engine and drawing frame, or the rovings produced on the slubbing, intermediate, and roving frames, or the yarn when spun on the mule or throstle, or any of them, to the action of steam, for the purpose of rendering the cotton pliable, and in a better condition for being worked than it is when operated upon in the usual manner. *Patent abandoned.*

303. S. ODDY and E. OLDFIELD. *Certain improvements in carding engines.* Dated February 3, 1863.

This invention consists in applying two doffers to the main cylinder of the carding engine, and in applying a fancy roller or revolving brush between the two doffers. The object of the invention is to deposit on the second doffer the fibres that have been carried by the main cylinder beyond the first doffer. When this improved carding engine is at work, the greatest part of the fibres are deposited on the first doffer, and the remaining fibres being acted upon by the fancy roller or brush, are raised or loosened on the main cylinder and deposited on the second doffer. Both the doffers are stripped by combs or other stripping instruments. *Patent abandoned.*

304. J. FLETCHER and H. BOWER. *An improved injector or apparatus for feeding boilers with water.* Dated February 3, 1863.

This injector consists of one pipe coiled spirally around another pipe, or of a pipe having a straight passage through its centre, and a crust sufficiently thick to admit of a spiral passage being formed therein around the central passage. The spiral passage opens at one end into a water-supply chamber, and the other into a discharge or injection chamber, which is to be attached to the ordinary feed pipe of a boiler. The straight passage is connected at the water chamber end to the pipe which opens to the steam chamber

of the boiler, and the other end terminates in the discharge or injection chamber at a point near to, and concentrically with, the outlet or orifice of the feed pipe. The apparatus is provided with taps or valves for regulating the flow of steam and water. *Patent completed.*

305. A. T. BLAKELY and J. VAVASSEUR. *Improvements in projectiles for ordnance.* Dated February 3, 1863.

These inventions consist in forming projectiles with grooves on the body and at the rear end thereof for receiving lead or other soft metal. The patentees prefer to form these grooves at an angle to the axis of the projectiles, and in the reverse direction to that of the rifling of the gun in which they are to be used; but the grooves may run parallel to the axis, and may be more or less long and deep, according to requirements. When the projectile is ready for use, there are alternate layers or strips of lead or other soft metal and iron or other metal of which the projectile is formed, round the circumference thereof, the iron or other metal thus protecting the lead or soft metal from injury. *Patent completed.*

306. T. L. JACOBS. *Improved mode of, and apparatus for, cleaning casks.* Dated February 3, 1863.

This invention consists in filling, or nearly filling the casks with water, and then introducing steam or air under pressure into the water, so that the latter may be put in a state of ebullition. *Patent completed.*

307. W. G. VALENTIN and F. LEVICK. *Improvements in generating combustible gases, and in the apparatus employed therefor.* Dated February 3, 1863.

This invention relates more particularly to the generation of gases for heating purposes, such as heating, puddling, and other reverberatory furnaces, and evaporating liquids, heating boilers, and generating steam, and for any other purposes in which the combustion of such gases may be serviceable. The object of the invention is to produce, in an expeditious and economical manner, large volumes of combustible gases, consisting chiefly of hydrogen and carbonic oxide, which can be obtained by the combustion of coal, wood, peat, tar, or other carbonaceous substances, by means of atmospheric air and steam. The invention cannot be described without reference to the drawings. *Patent completed.*

308. W. E. NEWTON. *Improvements in reflectors.* (A communication.) Dated February 3, 1863.

This invention consists in the employment of a system of glass plates, which serve to conduct or direct the rays of light. These plates, which may be termed refractors or projectors, which is a more technical term than reflectors, are placed vertically above a light, and present, on the one hand, a row of prisms superposed with horizontal bases, and, on the other hand, a row of prisms or flutings in a vertical direction. The light which passes through this plate, therefore, undergoes two changes of direction occasioned by the refractions produced by the inclined faces of the glass. *Patent completed.*

309. G. HARTON. *Improvements in wood paving.* Dated February 4, 1863.

This invention consists in placing a metal ring or hoop round the wood block, and laying down the same in the ordinary manner in wood pavements. The ring or hoop would be usually fixed round the upper end of the block, either by driving it upon a reduced end, or upon a shoulder prepared for that purpose; or the ring or hoop may be fixed on the block by heating the same, and fitting it on while hot. The blocks would be either square, circular, lozenge shape, hexagonal, or other form usually applied to wood pavements, and the ring or hoops to be fitted on the same would be of similar form. The upper and lower edge of the ring or hoop would generally be level or straight, but the inventor would sometimes indent the same on the upper edge. The rings or hoops would be usually made of iron or galvanized iron, but in some cases they would be of copper or brass. *Patent abandoned.*

310. J. MELLOR. *Improvements in apparatus to be used in distilling, subliming, and drying.* Dated February 4, 1863.

This invention consists in applying to vessels or retorts in which the various processes of distilling, sublimating, or drying are performed, a series of scrapers, having an angular, semicircular, or other suitable form, to which a reciprocating motion is given by cranks or other equivalent agents, thereby causing the vegetable, animal, or mineral substances under operation to be continually turning over, and at the same time moving forward. *Patent completed.*

311. T. E. TALLENT. *Improvements in the manufacture of leather, and in machinery for that purpose.* Dated February 4, 1863.

This invention is carried out as follows:—Upon two side frames is placed a table on which the hide or leather travels, and upon the same frames, and immediately above, is mounted a shaft on which is fixed a number of knives or scrapers, so arranged as to give a continual pressure upon the hide or leather; and to these knives is given a circular motion, so that the knives being driven at a proper speed by means of suitable pulleys and belts have action upon the hides or leather under them, and by this means the hide or leather is gradually carried forward, and thus the operation is completed. *Patent abandoned.*

312. T. BRADFORD. *Improvements in machinery or apparatus for washing, wringing, and mangling clothes or other textile fabrics.* Dated February 4, 1863.

This invention consists of a method of utilizing atmospheric air or steam in the process of washing, by a suitable arrangement and formation of vessel or washing compartment, and a novel construction of floating rubber or dash for the collection of atmospheric air or steam, and its forcible distribution through the washing ley and fibre, simultaneously with a rubbing action thereon, and which dash the patentee works upon one or more suitable inclines, one or both ends of which dash (as may be found desirable in its application either for hand or steam power) to be made in the form of, and to act alternately, as a suction valve or float and air piston, the centre being of metal, wood, or other open work for rubbing purposes, and for the admission and emission of air, steam, and water, as alternately drawn in, and expelled by, the other part of the dash. In that part of the single and double dash which works at the top of the incline, he proposes to fix a weighted roller to act as a rolling or sliding anchor or working centre for the float end, the floating power of which end he also proposes to assist by a suspensory elastic spring or band, or other convenient and suitable means. For wringing and mangling he introduces an improved combination and application of spring lever and spring, which spring lever and spring he makes of spring steel or any other suitable material, so that, while the maximum of pressure is attainable by the fulcrum of such levers, any required maximum is obtained by the ends of the lever coming into contact with any fixed resistance, or more particularly and more effectively when the end of such lever comes into contact with spring bars or plates, or a fixed buffer of india rubber, or a spiral spring, or any other similar combination of spring and lever. For mangling, the application of this form or means of pressure is particularly desirable, for which he adopts a combination of wood and cylindrical metal roller alternately for the portable roller, and a cylindrical metal roller. *Patent completed.*

313. G. HASELTINE. *Improvements in the mode of uniting metallic surfaces.* (A communication.) Dated February 4, 1863.

The patentee claims uniting thin and thick metallic sheets or plates by means of metallic rivets combined with simple apertures in the thin facing sheets, and enteriorly enlarged cavities in the thicker underlying plates of metal, substantially in the manner, and for the purpose set forth. When the invention is used for the purpose of protecting with a facing of copper the hulls of iron-plated vessels, or other iron surfaces exposed to the action of water or other liquid, the patentee claims the use of a thin layer of india rubber, gutta percha, or other insulating substance or material, when interposed and combined with the outer copper facing and the iron surface beneath, the same being rivetted and secured substantially as set forth. *Patent completed.*

314. G. T. BOUSFIELD. *Improvements in postage, revenue, and other stamps, and in apparatus for post-marking and cancelling postage and other stamps.* (A communication.) Dated February 4, 1863.

The nature of the first part of this invention consists in providing a postage, revenue, or other stamp, with perforations across the same, so that it may readily be separated into two parts, and in covering one part of such stamp below or above the said perforations with glue or other adhesive matter, while the remaining part of such stamp shall remain without any adhesive substance whatever, so that one part of the said stamp shall adhere to the letter, envelope, or packet on which the same may by law be required or used for the payment of postage, tax, or otherwise, while the remaining part shall not so adhere, but be free therefrom, whereby that part may be separated from the other part remaining upon, and adhering by means aforesaid to the letter, envelope, or packet, and thereby cancel the said stamp, and thus and thereby prevent a reuse for any purpose whatever; by this means also the labour and expense of cancelling such stamps by any instrument with ink is saved. The nature of the second part of the invention consists in so constructing apparatus for cancelling stamps that the same shall cut the postage stamp or any stamp similar thereto without injury to the contents of the envelope or packet enclosed therein, and at the same time cause a heavy circular mark upon the inside and one upon the outside of that part of the stamp or letter frank cancelled by the cutting device, so that the said postage stamp or letter frank shall readily show cancellation in ink, and when removed from the letter or packet on which the same may have been cancelled it shall be reduced to parts or pieces, whereby a second use of the said stamp or frank is thus prevented, though it may have been previously cleaned by a chemical or other process. It also consists in the employment and combination of a cancelling stamp with a cutting and inking device thereon, with a post-marking or dating stamp, so that the cancelling of the letter-frank and the post-marking on the envelope or packet shall be effectually done at the same operation. *Patent completed.*

315. J. J. HAYS. *An improved hot air stove where peat charcoal is the fuel employed, and for the method of using peat charcoal or other suitable fuel, in connection with the said stove, or other stoves, for the purpose of purifying or filtering the gaseous products of combustion.* Dated February 4, 1863.

This invention is not described apart from the drawings. *Patent completed.*

316. L. J. H. MARVILLE. *A covering for the ears made of india rubber, gutta percha, or other materials.* Dated February 4, 1863.

The apparatus the subject of this invention is usually made of india rubber, and is moulded externally to the external shape of the ear. The size of the auricle of the ear varies considerably with different individuals, as well as its shape, which is very irregular, but which may, nevertheless, be generally described as an oval, the greater diameter of which would be vertical, and the larger end turned upwards, curved in various ways, pressed from the outside inwards. This oval extends to the adjoining parts. These coverings for the ear present all the projections and hollows of the external face of the ear, which are from top to bottom. *Patent completed.*

317. Z. M. PARKES. *An improvement in iron and other metal bonds in use for building.* Dated February 4, 1863.

This invention consists of a band or strip of iron, or other metal, with transverse teeth, ridges, ribs, or projections pressed out of the solid, and so raised at intervals on each side of the strip or band for or on the whole width thereof. These projections are intended to be laid in the cement or mortar, or between the courses, or in the joints or interstices of the bricks, stones, or building materials, so that the bond thus held prevents the materials from giving or slipping out of place. *Patent abandoned.*

318. W. T. WESTON. *An improved spring catch or fastening applicable to windows and other useful purposes.* Dated February 4, 1863.

This invention is not described apart from the drawings. *Patent completed.*

319. B. RUSS. *Improvements in the construction of iron ships or vessels, and of armour applicable thereto.* Dated February 4, 1863.

This invention, so far as it relates to armour plates, consists in constructing such plates of iron and steel, in two or four distinct parts, which may be put together as follows:—If made of two parts, the first portion of the armour plate is the "back," and is composed of forged or rolled iron of suitable length, width, and thickness. The second portion is the steel face, and is composed of cast or wrought steel, or Bessemer steel of suitable length, width, and substance. The steel face may be laid on the iron "back," and the two plates may be then subjected to the heat of a blast furnace, or otherwise, till heated to the requisite degree for welding. The two portions may then be hammered or rolled into one solid armour plate. If made of four portions, the patentee adds to the first series of two portions already described, a second series of two portions of like materials, in the same order as before, and heats and welds as before described. The improvements in the construction of iron ships or vessels, as described in the specification of this invention, are too diffuse to be quoted here at sufficient length for an intelligible abstract. *Patent completed.*

320. C. and D. FAULKNER, J. FAIRLEY, and W. C. STIFF. *Improvements in the manufacture of gun barrels.* Dated February 4, 1863.

The patentee claims converting or carbonizing partially-formed tubes of iron or steel for gun barrels, technically called "moulds," whether the same be formed by coiling, welding, drilling, punching, or casting, and then elongating or finishing the same in the ordinary way now commonly pursued. *Patent completed.*

321. J. A. MANNING. *Improvements in the treatment of nightsoil and other waste products, and for the manufacture of manure therefrom.* Dated February 4, 1863.

The main feature of this invention consists in treating nightsoil with sulphuric acid, in the manner described in the specification. *Patent completed.*

322. W. STOKES. *Improvements in the construction of window sashes whereby the same are rendered more weather-proof, and secure against draughts and burglars, and permit the outside to be cleaned with the facility of the inside.* Dated February 4, 1863.

The invention consists in making the sash proper a little less than the window frame between the beads, and occupying the difference on each side with additional stiles, to which the cords are to be attached in the ordinary way for counterpoising the weight of the sash; and these outer stiles are attached at or near the bottom or lower inner edge of the sash by suitable hinge joints, which permit the sashes, when liberated by the fastener, to fall inward, say, into a horizontal or other convenient slanting position, thereby rendering it as convenient to clean or renew the glass in case of breakage as if the sash were removed from the window frame altogether. On the edges of the sash and corresponding edges of the outer or hanging stiles, the inventor applies metal strips that overlap each other, thereby rendering the joints entirely weather-tight, and secure from draughts; and this same principle he applies to the outside of the top rail of the lower sash, and the inside of the bottom rail of the top sash; by which means the over-lapping of the metallic strips not only excludes the draughts, but also prevents the insertion of any knife-blade or other contrivance to undo the sash fastener, which may be of any ordinary construction. To prevent the sashes falling forward into the room from the pressure of the wind or otherwise should the fastener be left undone, and the lower sash slightly elevated, he purposes using spring or other suitable catches or detents that are brought into action for uniting the sash with the hanging stiles, so that, when the sash is in position, the outer slide shall be united to it at the top, and either of the lower or top sash, although it is not essential to the top sash, as metallic pins may be secured to the top rail fitting metallic sockets correspondingly applied to the top of the sash frame, so that as the top sash is slidden up, the pins will enter the metal sockets, and thereby hold it in position. *Patent abandoned.*

323. W. T. MABLEY and W. T. CHEETHAM. *Improvements in blowing organs and other such musical instruments, parts of which improvements are also applicable to obtaining motive power for other purposes.* Dated February 5, 1863.

This invention relates—1, to apparatus to be used as a substitute for the ordinary bellows used in blowing organs and similar musical instruments. For this purpose the inventors employ a flexible bag or tube disposed in a cylindrical form, and cause it to revolve against a roller, or a roller to revolve thereon, so that the air as it is drawn in at one end is expelled at the other. Another part of the invention relates to a method of giving motion to bellows of organs, applicable also to other cases in which comparatively small motive powers are required. For this purpose they employ a wheel having vanes or teeth upon its circumference, and on these they cause water to be injected in such a condition as to form a jet, and acting therefore by impulsive force, the said wheel being mounted so as to revolve free of the fluid. At the backs of the vanes or teeth they leave openings so as to allow the water to escape readily. For the supply water they propose when available to use the ordinary public service pipes. In order to regulate or govern the motive power, they close or partially close the orifice of the jet, and cause a conical spindle or wedge-formed piece to be drawn backward or forward, so as to contract or enlarge the opening. *Patent abandoned.*

324. J. GILL and J. PARKIN. *Improvements in apparatus for polishing yarn, twine, threads, and other similar materials.* Dated February 5, 1863.

This invention consists in the combination and arrangement of the polishing and conducting rollers with and in relation to the ordinary heated cylinder, whereby the yarn, twine, thread, or other material is polished on both sides, and protected from the ordinary liability to breakage. For this purpose the ordinary roller covered with hair, cocoanut fibre, or other suitable material, is arranged so as to polish the outer surface in the ordinary manner. The yarn, twine, thread, or other material is caused to pass from this roller over the ordinary tin or wooden guiding roller, thence over a smooth conducting roller, whence it passes to a second polishing roller with a roughened surface so placed as to act upon the inner surface of the yarn, twine, thread, or other material, which thus becomes polished on both sides. By this arrangement of the several rollers the strain on the yarn, twine, thread, or material thus becomes distributed in such a manner as to prevent any under pressure on any particular part thereof. *Patent completed.*

325. W. BETTS. *Improvements in apparatus for applying metallic capsules to bottles.* Dated February 5, 1863.

This invention relates to a peculiar construction and arrangement of apparatus for applying metallic capsules to bottles, whereby greater economy and simplicity of construction are obtained, with increased efficiency of action. According to this invention, the compressing loop—which is made by preference of what is commonly known as "catgut"—is always maintained ready formed, and in an open state fit to receive the neck of the bottle, in place of requiring to be made by hand at every fresh operation. One end of the gut is secured to the side of a metal plate, having a semicircular or other suitably formed notch made therein for the reception of the bottle neck. The gut then passes, in the form of an open loop, under and in front of the bottom of the notch, and over the top, and finally ascends to a connecting rod secured to a treadle, which works on fixed centres in the back portion of the capsuling stool, or in any convenient part of a workbench. The lower portion of the loop is held down in its place, just below the edge of the notch in the plate, by a wire connected to a weight, or to an india-rubber or other spring, and the whole is carried by an upright post, fixed either to the front of the stool or to a workbench or table. The treadle having been depressed in order to compress the loop of gut round the capsule on the neck of the bottle, is raised again on being released, so as to open the loop and liberate the bottle by a spring, the inherent spring in the gut itself serving to maintain the loop open when not acted upon by the treadle. A check or projecting piece is fitted to or formed on one side of the notch in the plate, for the purpose of retaining the loop in its place close against the metal plate. *Patent completed.*

326. H. DIRCKS and J. H. PEPPER. *Improvements in apparatus to be used in the exhibition of dramatic and other like performances.* Dated February 5, 1863.

An extension of time for the completion of this patent having been petitioned for, the documents relating to the invention cannot at present be seen.

327. E. INGHAM. *An improved apparatus for, and means of, dyeing the wool in the sliver from which "mixture yarns" may be drawn.* Dated February 5, 1863.

Heretofore, what are termed "mixture yarns" have been produced by drawing from two slivers, the one plain or undyed, and the other of any desirable colour. This improvement consists in dyeing slivers in such a manner that "mixture yarns" may be drawn from a single sliver. *Patent abandoned.*

328. R. A. BROOMAN. *Improvements in machinery for supplying and spreading wool and other filamentous materials on belts, tables, and other surfaces to be afterwards carded and otherwise acted on.* (A communication.) Dated February 5, 1863.

This invention is not described apart from the drawings. *Patent completed.*

329. J. PATERSON. *Improvements in buckle and hook fastenings.* Dated February 5, 1863.

This invention consists of two parts, which may be used together or separately. The first is in the form of a buckle, and the invention therein consists in forming the buckle all in one piece, as hereafter stated. The teeth or prongs of the buckle are formed by slotting out parts from the buckle plate, and by leaving parts projecting beyond portions removed from between these projections. A bar is left below and at a slight distance from the projecting parts in prongs, and below this bar a piece is slotted out to allow passage to the material to which the fastening is to be applied. The upper part of the plate above the bar is bent slightly backward. The hook fastening, which may be formed in the buckle flap—or, as before stated, may be used separately—consists of the end of the flap (or end of a plate) turned over, and with the joint made to project and bend slightly downward; a tongue stamped or cut out of the flap or plate is then shaped and brought over the joint and end of the turned-up hook, whereby a safety spring hook is produced. *Patent abandoned.*

330. R. A. BROOMAN. *Improvements in apparatus for tuning pianofortes.* (A communication). Dated February 5, 1863.

The object of this invention is to facilitate the tuning of pianofortes. In order to tune two strings or make two strings agree, they must be of the same nature and possess homogeneity of sound; and to obtain this result it is necessary—1, that they be made to vibrate simultaneously; 2, that the vibrations run together in the same sounding board; 3, that they follow the same circumvolutions, and that they are reverberated by the same surfaces. The apparatus which forms the subject of the present invention fulfils these conditions. The inventor arranges a sonometric string parallel to the strings of which it is the type; it rests on the same bridge and acts on the same sounding board. The longest string in the pianoforte is supported on a moveable nut, guided in a longitudinal direction by a register for indicating externally the sound the type of which is required. The string, lengthened or shortened according to the proportions of the sonometer, by means of an additional pedal, gives successively the typical sound in the score to be produced. Thus, to tune an instrument, the typical string and the string to be tuned are simultaneously struck, one with the foot (because the pedal moves a hammer), the other with the left hand, while the right hand acts on the peg of the second string to raise or lower it in unison with the first; the tuner proceeds with these strings as if they belonged to the same key. This tuning apparatus may be fitted inside or outside the pianoforte. *Patent completed.*

331. B. F. BATES. *Improvements in cannon, and in projectiles to be used therewith.* (A communication.) Dated February 6, 1863.

In constructing cannon according to this invention, the inventor forms a hole through the breech, and this hole is smaller than the bore, and is parallel and concentric with it. Each projectile is provided with a long rod or bar, which, in loading the cannon, is passed through the hole in its breech. At the front end of the rod there is an enlargement or head, which, however, is smaller than the bore; this head may be solid, or it may be formed into a shell, and behind this enlargement is placed a loose disc, which fits the bore accurately. The periphery of this disc may, if desired, be formed of soft metal, and may also have lubricating material combined with it. The rod at the rear end of the projectile is, by preference, polygonal in section, with each of the sides winding spirally around the rod from end to end of its length, as though the rod were twisted. The hole in the breech end of the cannon is formed to fit and correspond with the bar, so that when the piece is fired, the projectile, in addition to being propelled forward, will, at the same time, be caused to revolve on its axis. The loose disc behind the head of the projectile, by preference, does not rotate with the projectile, but the rod of a projectile turns in a hole in the disc. As soon as the projectile leaves the gun, the resistance of the gun will cause the disc to slip off the bar at its rear end; or the disc may be made to separate into two or more pieces as soon as it leaves the gun. If desired, the hole through the breech end of the gun may be closed as soon as the rear end of the projectile passes out of it, by means of a sliding piece pressed forward for that purpose by a spring. The hole in the breech end of the gun may be provided with a close-fitting plug; the gun can then either be used to propel a shot, such as above described, or, when the plug is fixed in the hole, the gun may be used as an ordinary smooth-bore gun. *Patent completed.*

332. A. HANTZMANN and T. A. ROCHASSEN. *An improved boring bench for gun barrels.* (A communication.) Dated February 6, 1863.

Provisional protection has not been granted for this invention.

333. T. BLAKELY and B. MEAKES. *An improved lead and pencil sharpener.* Dated February 6, 1863.

This invention consists of a piece of hard wood with a hole drilled into one side, such hole being conical at one end, and parllel at the other end; opposite the conical end there is a recess cut in the wood to admit of a knife, which is made fast in this recess by means of a screw; there is a slot hole in the knife by which arrangement the latter can be regulated to cut with the greatest accuracy, and can be taken out, sharpened, and replaced at convenience. *Patent abandoned.*

334. A. JOHNSTON. *Improvements in the propulsion of vessels.* Dated February 6, 1863.

This invention relates to a method or system of propelling vessels by means of an improved propeller, consisting of one or more pieces of submerged cylinders, fitted with pistons of the form hereinafter more particularly described. In carrying out the invention, the patentee makes use of one or more pairs of these cylinders and their pistons, and he places them water-tight below the light-load water-line in the stern or other suitable part of the ship. The cylinders and their pistons are used in pairs, each pair of pistons by the piston rods being connected to each other by means of a rocking beam or beams placed inside the ship. By reason of being connected to this rocking beam the pistons are balanced and kept in their relative positions. The propelling pistons (which he calls the water pistons, to distinguish them from the steam pistons) are formed with projections or noses which extend from the piston head and packing of the water pistons towards the mouth or open end of the water cylinders. These projections or noses must be made of a size sufficient to fill up the whole area of the water cylinders when the pistons are drawn back, leaving just space enough to avoid friction or rubbing against the inner surfaces of the said water cylinders, and the ends of the said projections should be slightly dished or hollowed out so as to enable them to take a better hold of the water. The projections may be made of cast iron or other suitable material, and should be made hollow, but they must be made of such weight as to be equal or thereabouts to the weight of water which they displace, so that, when the pistons are extended to the full length of the stroke, there may be no strain on the water cylinders. *Patent completed.*

335. G. STEVENS. *Improvements in means or apparatus for effecting a regular supply of air or aeriform fluids for various purposes.* Dated February 6, 1863.

This invention is carried into effect as follows:—Within a suitable outer chamber the inventor applies an internal vessel, which is affixed to an axis carried by the outer chamber, and is formed into one or more spiral chambers or compartments, somewhat as the thread or the threads of a screw, with inlet and outlet passages. The outer chamber is partly filled with water or other fluid, which also partly fills the chamber of the internal vessel, and this outer chamber is also provided with inlet and outlet passages, the latter passing to within the inner vessel. Motion being given to the internal vessel by a pulley and weighted cord or band, or by suitable wheelwork, air will flow in by the inlet passages, and be conducted along the internal screw-like chamber or chambers to the outlet passage, and thence by suitable pipes or conduits it may be conducted in a uniform stream for various purposes, such as for the supply of atmospheric air to the photogenic gas light, or for supplying air to apartments and other places. The speed and consequent pressure of the current may be varied by adjustment of the power employed to give motion to the internal vessel. *Patent abandoned.*

336. A. CLARK. *Improvements in knife-cleaning apparatus.* Dated February 6, 1863.

This invention consists of a rectangular kind of box, or it may be of other form, of a length rather more than the longest knife-blade to be cleaned, and a breadth of some 4 in. or 5 in. Inside the bottom of the box the inventor applies a surface of leather, or it may be in strips across it, on which surface the side of the knife being cleaned lies: a slit is formed in the end of the box at which the blade is introduced. Within the outer case is fitted another box to slide up and down freely; it is of much less depth than the outer case, and it is pressed down on the latter surface by springs above or abutting on, and thrusting from the lid of the case. The face of the inner box opposed to the leather surface before mentioned has also strips of leather placed and fixed across it, and, being pressed downward, exerts a pressure on the knife-blade placed between the leather surface, which will be quickly cleaned by a motion of thrusting in and withdrawing the blade being communicated to it by hand. In this way two knives may be cleaned simultaneously, one in each hand of the operator. Brick-dust or other powder is introduced at the top of the case in the centre, which communicates with a small trunk or channel leading into the inner box, which may be more or less filled with it, and which finds access to the cleaning surfaces through holes in the bottom between the strips or surfaces of leather. *Patent abandoned.*

337. R. A. BROOMAN. *Improvements in carding engines, whereby slivers are formed into threads ready for spinning.* (A communication.) Dated February 6, 1863.

The object of this invention is to cause the slivers to leave the card fine enough to be spun directly and without any further drawing than is necessary to give the thread the desired tension during the torsion, as hereafter described. The invention is based upon the arrangement of the supply cylinder, the sliver guides, the great speed and short stroke of the detaching comb, and especially on the combination of the rapidly-rotating funnels, and of a friction roller (*rota frotteur*). Without this triple combination of the comb, of the funnels, and of the friction roller, it is believed that a sliver cannot be made to issue from a carding engine in a state of fine thread like that produced by this invention. The arrangement of the slivers and of the partitions which separate them at short intervals on the large drum, so that the number of the slivers on the drum of the carding engine may be increased, also forms part of this invention. *Patent completed.*

338. W. ROBINS. *Improvements in the construction of fire-lighters or faggots.* Dated February 6, 1863.

When manufacturing what is known as the "wheel" form of fire-lighter, the inventor proposes to make all the radial spokes of short pieces of split wood, and to connect these pieces together at the centre by inserting a key into a saw-cut made in the abutting inner ends of the spokes. The periphery he forms as usual, and inserts a tuft of bass or shavings in the centre to facilitate the ignition of the faggot. When forming rectangular faggots or fire-lighters, instead of using long pieces arranged parallel to each other, he uses short pieces of split wood for the inner bars, runs a saw-cut through their inner abutting ends, and connects them together by a long key, the ends of which butt against the side pieces. Similarly, he runs a saw-cut through the outer ends of all the pieces, and ties them together, as heretofore, by longitudinal keys. The inner key first mentioned serves to increase the strength of the structure, and the disposition of the keys admits of the parallel bars of one faggot packing in the spaces of an adjoining faggot. *Patent abandoned.*

339. J. PRICE. *Improvements in signal lanterns suitable for being used in open boats.* Dated February 6, 1863.

The peculiarity of this invention consists in combining the parts of a lantern in such manner that at one time (that is when a boat is at anchor), the lantern may be capable of showing a white or bright light all round, and then for a time (that is when the boat is in motion) the part of the lantern which is glazed all round with white glass may be covered interiorly or exteriorly with a screen or screens, consisting of three parts or divisions, one part or division being opaque, one part or division being composed of red glass, and the third part or division being composed of green glass, so that the light in the lantern will be only thrown forwards through the red and green screens, whilst the light will be stopped from being seen at the third or back side of the lantern. *Patent completed.*

340. A. D. TIVNANN. *Improvements in holster boxes for screws or pins to work in, and in the manufacture thereof.* Dated February 6, 1863.

In carrying out this invention the inventor uses boxes of brass, gun metal, or copper for the iron or hard metal screws or pins to work in, and he makes such boxes by casting the same on to the screws or screwed pins intended to work in these same with the threads thereon. The patterns of the outside shape of these boxes is prepared in the usual manner. The object of the invention is to save wear and tear, and produce an article which shall, when useless for its original purpose, be valuable as old metal. *Patent abandoned.*

341. A. ELLISSEN. *An improved method of treating sheeting and plates of iron to be used in shipbuilding and marine constructions for protection against marine animals and marine plants.* Dated February 6, 1863.

In carrying out this invention, the inventor treats iron sheeting or plate with cyanide of potassium or potash, or other material of equivalent effect, for the purposes of rendering the same useful for shipbuilding purposes and marine constructions, thereby protecting such ships

constructions against marine animals and marine plants. Patent abandoned.

342. J. CAMERON. *Improvements in the manufacture of iron and alloys of iron.* Dated February 7, 1863.

The patentee claims the manufacture of iron by mixing with the iron ore the quantity of fuel and flux necessary for its proper reduction, grinding, and intimately mixing these materials and forming them into blocks which are then smelted. He also claims the production of alloys of iron by the employment of ores of two or more metals in the making of the blocks, the process being otherwise similar to that above claimed for the manufacture of iron. *Patent completed.*

343. J. SIRON. *A new medicinal preparation for internal and external application.* Dated February 7, 1863.

This new medicinal preparation is composed of the following plants, culled when at maturity, and in possession of all their aroma, both flower and leaf being used, unless one or other be specially indicated:—1, Mentha viridis; 2, Artemisia foliis pinnatisidis (vul. mugwort); 3, Hypericum perforatum; 4, Lavendula spicata; 5, Achillea millefolium; 6, Hypericum frigademonum; 7, Plantago arenaria; 8, Hissopus officinale; 9, Thymus serpillum; 10, Thymus vulgaris; 11, Teucrium foliis cordatis undulatis; 12, Artemisia absinthium; 13, Salvia officinale; 14, Fœniculum officinale; 15, Anettrum fœniculum; 16, Apium Petrosilinum; 17, Borrago officinale; 18, Lilium candidum; 19, Flores Lambuca; 20, Spirea almaria; 21, Fores tilia parviflorœ; 22, Flores rosarum centifoliarum; 23, Flores citri medicœ; 24, Rosmarinus officinale; 25, Verbena officinale; 26, Santolina; 27, Angelica; 28, Lythrum salicaria; 29, Anthemis pyrethrum. The inventor places the flowers and leaves above enumerated in a glass vase or bottle, mixing them in about equal proportions; he then presses them gently down with the hand, and pours upon them as much wine brandy as will cover them, leaving the whole to macerate and steep at an ordinary temperature during thirty days, when he filters, and the liquor is ready for use. *Patent abandoned.*

344. J. MALLISON. *Certain improvements in the process and method of dyeing yarns.* Dated February 7, 1863.

This invention consists in dyeing yarns whilst in an extended state, as in sizing and dressing machines, so that they may be dressed and wound on to the finished or weavers' beam in a dyed state, whereby the subsequent dressing (to which warps dyed in the usual manner are submitted) is dispensed with. *Patent abandoned.*

345. G. TURNER. *Improvements in means or apparatus for mincing or cutting meat or other substances.* Dated February 7, 1863.

One part of this invention relates to apparatus in which one set of cutting or dividing blades or teeth are applied to a horizontal axis, and the other set of blades or teeth are stationary in the barrel or cylinder, and has for its object improved means of supporting the outer end of such axis, or that farthest from the handle or driving means, adapted to facilitate the passing away of the meat or other substance as cut or minced. For this purpose the patentee forms the last of the fixed blades or teeth into the support for the outer end of such axis; or he forms the outer support with inclined or knife edges to act in carrying the substance cut in a forward direction. Other of the fixed blades may also aid to support the axis. He also, in some cases, applies the outer revolving blades or dividers beyond such support. *Patent completed.*

346. W. T. COOPER. *Improvements in distilling apparatus.* Dated February 7, 1863.

This invention consists in affixing to the head or beak of the still a jacket cylinder formed by two cylinders one within the other, leaving a small space between them in which part of the spirit to be distilled or rectified is introduced. The inner cylinder is shorter by about one-third than that of the outer cylinder, and contains several moveable and perforated pans or dishes, upon which the charcoal, berries, roots, or other substances or materials are placed when required. There is also a perforated moveable cover to the inner cylinder. When the still is in operation, the spirit in the jacket or space between the two cylinders rises and overflows the perforated cover of the inner cylinder and trickles through the perforated pans; the hot vapour from the still meets it, and converting a portion of it into vapour, carries it into an apparatus, which the inventor calls "quadruple analyser," the more aqueous portions running into the still to be converted into vapour. The quadruple analyser consists of an upright tube or cylinder partially surrounded with water, whence the purer portions of the vapour pass through regulated openings into three other tubes or cylinders for a complete separation of the essential oils; the vapour then passes into the ordinary worm or refrigerator. The portions collected while passing through the quadruple analyser fall into a chamber in connection therewith, and are thus drawn off as reconveyed to the still by suitable pipes. *Patent abandoned.*

347. C. PARIGOT and A. GRIVEL. *Combination eccentric locks.* Dated February 7, 1863.

This invention relates to an improved keyless lock with various combinations applicable for all kinds of fastenings. The patentees term this an eccentric lock, the throw of the bolt being effected by eccentrics; this arrangement of lock offers the following advantages:—1, It dispenses with the use of a key, which may be mislaid or lost. 2, It dispenses with springs, and so leaves the interior of the lock free, which permits of making the bolt much stronger, while the lock works much easier, and is less liable to derangement. 3, Its combinations render the lock unpickable, and these may be multiplied to any degree by increasing the number of rings on which the principle of the combination is based. 4, The lock is hermetically closed, and is thereby kept clean, may be made cheaply, and will last a great length of time. *Patent completed.*

348. W. CLARK. *Improvements in the application of gas for the preparation of woodwork generally and iron ships for their better preservation and reception of paint or other protecting coating, and for disinfecting ships, hospitals, and other places.* (A communication.) Dated February 7, 1863.

In carrying out this invention, a jet of gas in ignition, which may be either lighting gas or gaseous oxide of carbon, is projected on to the surface of the hull, and in order to render its action more efficacious and char surfaces with greater rapidity, the gas should (as stated in a former patent) be condensed before issuing from the nozzle, or to a certain pressure; and also to quicken combustion heated air should be injected by means of a blower in combination with the gas. Now this invention further relates to new applications of the said mode of carbonization for searing or charring surfaces intended to resist destructive influences. For example, iron ships require coating with a protective paint, and on returning from a voyage the old coating must be removed by scraping, and replaced by a fresh one. *Patent abandoned.*

349. J. JAMES. *An improved covering for hooped skirts.* Dated February 7, 1863.

The present invention is intended to prevent the destruction of the skirt by the friction of the hoop, and consists in the application of a material—viz., leather, that will resist and prevent the friction alluded to, and that will at the same time form an ornament as a trimming to such articles of dress. *Patent abandoned.*

350. J. MILLER and W. STRUTHERS. *Improvements in securing the corks, stoppers, or lids of bottles, jars, and other similar vessels.* Dated February 7, 1863.

Under one modification or system of arrangement two holes are formed in the neck of the bottle or jar during the progress of manufacture, or while the bottle, jar, or other similar vessel is in a sufficiently softened state to admit of the material being easily pierced. These holes are by preference made in the thickened part or rim which forms the mouth of the vessel, bottle, or jar; and they are made opposite to one another, so that when the vessel is filled, and the cork or stopper is inserted, a short length of wire, a pin, or other retaining medium may be easily passed through the cork. *Patent abandoned.*

351. M. HACKFORTH. *Improvements in shades or reflectors for lighting purposes.* Dated February 7, 1863.

This invention relates to a new manufacture of shades or reflectors for lamps or lights of all kinds, and consists in forming them of porcelain or china. These materials afford an economical reflector or shade, which can at all times be easily cleaned from dirt and other impurities by simply washing them with water. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 20, 1863.

1549. G. Brixley, Maida-hill. Improvements in apparatus and implements for cleaning spoons and forks.

Dated June 27, 1863.

1614. T. Dunn, Windsor Bridge Iron Works, Manchester, engineer. Improvements in the construction and maintenance of the permanent way of railways.

Dated July 27, 1863.

1865. G. Haseltine, 12, Southampton-buildings, Chancery-lane, civil engineer. Improvements in coal oil lamps. (A communication.)

Dated July 28, 1863.

1872. A. A. Antoine Baron de Rostaing, Paris. An improved method of manufacturing iron and steel with cast iron taken in the subdivided state.

Dated August 1, 1863.

1909. E. Sutton, Palace-road, Well-street South, Hackney, silversmith. Improvements in fastenings for cigar cases, portemonnais, bags, and other like articles.

Dated August 10, 1863.

1971. R. J. Cunnack, Helston, Cornwall. Improvements in the manufacture of cartridges for blasting and projectile purposes.

Dated August 11, 1863.

1975. E. Myers, 2, Millbank-row, civil engineer, and H. Forbes, 6, Aberdeen-place, Maida-hill. An improved rotary pump.

Dated August 13, 1863.

1997. J. Ellis, Liverpool, millwright and engineer. Improvements in machinery for scouring, cleaning, and polishing wheat, rice, malt, grain, and other seeds.

1999. H. Winchcomb, 3, China-walk, Lambeth, London, labourer. Improvements in street letter-boxes and bags for the reception of post letters.

2001. T. Ashwin, Birmingham, accountant clerk. A new or improved dress fastening, which said fastening may also be applied to the fastening of braces, belts, and other bands, and to other like purposes.

2003. J. Henderson, Bradford, Yorkshire, carpet manufacturer. Improvements for preparing yarns for printing.

Dated August 14, 1863.

2008. C. Schiele, Manchester, engineer. Improvements in fans, pumps, and machinery for propelling air, fluids, or other substances by centrifugal force.

2011. E. Taylor, Salford, machinist. Certain improvements in machinery or apparatus for churning.

2013. F. J. Jones, Aldermanbury, London, manufacturer. Improvements in locks or fastenings.

2014. M. H. Lishman, Stockton-on-Tees, accountant. Improvements in machinery for punching and for marking plates in which holes are to be punched.

2015. M. Siegrist, Ewell, Surrey, gentleman. Improvements in railway brakes actuated by the pressure of the atmosphere.

2017. J. Wain, Manchester, mechanic. Improvements in machinery or apparatus for doubling or twisting yarns or threads of cotton and other fibrous materials.

Dated August 15, 1863.

2019. J. W. Hoffman, Rydon-street, Middlesex. Improvements in apparatus for producing optical illusions for stage effect in theatres or exhibitions.

2021. G. Yates, Oswaldtwistle, engine driver. An improved means or method of indicating the number of tubs or other measures or quantities of coal or other substance or material drawn from pits or mines.

2025. R. Smith, Hyde-road Paper Staining Works, Manchester, and J. Booth, Gorton, Manchester, manager. Improvements in the manufacture of paper-hangings.

2027. F. Flavell, Welton, Daventry, machinist. Improvements in shakers for thrashing machines.

2029. T. Brooks, Wyld's Rents, Long-lane, Bermondsey, engineer. Improvements in means or apparatus for the production of charcoal and other products from refuse tan and other woody substances.

2031. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved apparatus for printing. (A communication.)

2033. E. H. Bentall, Heybridge, Essex, agricultural implement maker. Improved machinery for thrashing corn and other grain or seeds.

2035. A. W. Parker, Bristol Soap Works, Bristol. Improvements in the manufacture of soap.

Dated August 17, 1863.

2037. A. M. Dearn, Greenstead Works, Colchester, engineer. A new centrifugal disc mashing machine.

2039. H. A. Bonneville, 24, Rue du Mont Thabor, Paris, and 38, Porchester-terrace, Bayswater. Improvements in the processes and preparations employed in spinning wool. (A communication.)

2042. T. Loftus, Preston, mechanical engineer. Improvements in apparatus for attaching to steam boilers and flues for the consumption of smoke.

2043. J. S. Crossland, Ashton-under-Lyne, engineer. Improvements in lubricating, and in arrangements and mechanism for lubricating the bearings, journals, or steps of spindles, shafts, axles, and other mechanism.

Dated August 18, 1863.

2045. J. Arthur, 1, Robert-terrace, Chelsea. An improved apparatus for the prevention, cure, and relief of hernia of every description, together with prolapsus uteri, uterine hemorrhage, hernia humoralis, and as a general support for enlargement of the abdomen from whatever cause proceeding.

2047. J. Brennand, Burnley, cotton spinner. An improved construction of firebars and apparatus connected therewith.

2049. T. Dobb, Rotherham. Improvements in chimney tops, which improvements are also applicable to coverings for ventilating shafts or flues for mines and other places.

2050. A. Cruickshank, Glen Park, Lanark, gentleman. Improvements in the manufacture or production of food for cattle and all other domestic animals, poultry, and game, and in the machinery or apparatus employed therein.

2051. J. Yates, Rotherham, iron master. Improvements in the manufacture and fitting or securing of armour plates, blocks, or bars, and in the machinery or apparatus employed therein, parts of which improvements are applicable to heavy forgings generally.

2053. R. A. Brooman, 166, Fleet-street, patent agent. An improved method of, and apparatus for, treating molasses, syrups, saccharine juices, and other products. (A communication.)

2055. C. H. McCormick, Chicago, United States, manufacturer of reaping machines. Improvements in reaping machines.

Dated August 19, 1863.

2057. W. Jackson, mechanic, 4, Spring-terrace, York-road, Lambeth. Improved arrangements of the parts in sewing machines using shoemakers' wax thread suitable for heavy boot or other leather work to which it may be applied.

2059. T. Howard, Hyde, Chester, cotton manufacturer. Certain improvements in machinery for spinning cotton, flax, wool, silk, and other fibrous substances.

2061. G. T. Bousfield, Loughborough-park, Brixton. Improvements in apparatus for feeding weft in hair cloth looms. (A communication.)

2063. G. Bonelli, Turin, engineer, and H. Cook, Gloucester-square, Middlesex, gentleman. An improved mode of, and apparatus for, producing by the aid of photography optical illusions of moving animals and bodies.

Dated August 20, 1863.

2066. W. and J. Galloway, Manchester, engineers. Improvements in steam boilers, and in steam and water gauges for the same.

2067. S. Hallsworth, Elland, near Halifax, and T. Platt, Fairfield, near Manchester. Improvements in the manufacture of certain colouring matters known as Prussian blue, Berlin blue, Paris blue, China blue, and Turnbull's blue.

2069. J. Fleming, Newlandsfields, Renfrew. Improvements in preserving the colours of dyed fabrics.

2070. J. Platt, Oldham, mechanical engineer, and W. Richardson, mechanical engineer. Improvements in machinery or apparatus for cleaning cotton and wool from seeds, burrs, and other extraneous matters.

2071. J. Platt, Oldham, mechanical engineer, and W. Richardson, mechanical engineer. Improvements in machinery or apparatus for winding narrow laps of wool.

2072. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the manufacture of cartridges. (A communication.)

2073. C. D. Hammond, Charlotte-street, Bedford-square, doctor of medicine. Improvements in apparatus for the treatment of certain bodily ailments.

Dated August 21, 1863.

2074. J. F. Hill, 23, Little St. Andrew-street, Upper St. Martin's-lane. An improved ventilating gas lamp or gaselier.

2075. J. Eccleston, Manchester, organ builder. Improvements in apparatus for economizing or regulating water power used for blowing organs or harmoniums, which improvements are also applicable for other purposes where an irregular motive power is desired.

2078. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in expressing and filtering oil from seeds, and liquids from other substances containing the same, and in apparatus employed therein. (A communication.

2079. W. Evans, Belgrave-street, Commercial-road East. An improved artificial fuel.

2080. R. Griffiths, Mornington-road, Regent's-park, engineer. Improvements in the construction of retorts or ovens for extracting oil from certain descriptions of cannel coal or other bituminous substances.

2081. E. Pope, Clonmel, Ireland, gunmaker. Improvements in breech-loading firearms.

Dated August 22, 1863.

2083. T. Pegram, 22, Cardington-street, St. Pancras, photographic artist. A plate holder for the photographic camera, adapted to carry different sized plates, each plate being on the same plane and in the same focus.

2084. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in closing powder canisters and other vessels. (A communication.)

2085. A. Watson, King-street, London, engineer. An improved method of, and apparatus for, inserting pictures in and withdrawing them from photographic albums.

2086. R. A. Brooman, 166, Fleet-street, patent agent. A new metallic alloy. (A communication.)

2087. L. E. C. Martin, 32, Albion-street, Hyde-park. Improvements in apparatus for heating and purifying water.

2088. S. Moore, Liverpool-street, Bishopsgate-street. Improvements in the means of, and apparatus for, electro-plating, said apparatus being also applicable to medical purposes.

2090. W. Benson, Leeds, machine and tool maker, and P. W. Greenwood, Leeds, mule spinner. Improvements in preparing and spinning wool and other similar fibres.

Dated August 24, 1863.

2092. A. Jobson, Darlington, Durham, colliery agent. Improvements in machinery for drawing or discharging coke ovens and loaking coke waggons.

2094. C. S. Grasset, Larnoca, Cyprus, Turkey. An improved double McCarty gin or machinery used for cleaning cotton from its seeds.

2095. A. Capello, 4, Rue du Repentir, Marseilles, currier. An improved method of, and apparatus for, glazing morocco leather.

2097. H. F. McKillop, Belvedere, Kent, captain in the Royal Navy. Improvements in cleansing ships' bottoms.

2098. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in air and gas engines. (A communication.)

Dated August 25, 1863.

2100. G. E. Lewis, Birmingham, gun manufacturer, H. Walker, Birmingham, machinist, and J. B. Wayne, Birmingham, machinist. Improvements in breech-loading firearms.

Dated August 26, 1863.

2104. T. Hopkins, jun., White Hart-place, Kennington-cross, coach beader. Improvements in carriage door handles.

2105. J. Taylor, Gomersall, Leeds. Improvements in the manufacture of soap. (A communication.)

2108. T. Westhorp, Falcon Works, Bromley. Improvements in machinery or apparatus for preparing cut rope, strands, or yarn for carding into oakum.

2109. R. Johnson, Manchester, iron and wire manufacturer, and G. Bedson, manager. Improvements in pointing wire rods or wire, in order to facilitate their introduction into draw plates.

2110. W. E. Newton, 66, Chancery-lane, civil engineer. Improved apparatus for extracting coal ores or other minerals or substances from mines, which apparatus may be also employed for raising and lowering the workmen and their tools or implements. (A communication.)

2111. J. Platt, Oldham, mechanical engineer, and W. Richardson, mechanical engineer. Improvements in stoves or grates.

2112. J. Fry, Chesham, Buckingham, engineer. Improvements in mashing machinery used in making fermented liquors.

2113. D. Blake, Manchester. Improvements in shaping and punching metallic articles, and in the machinery or apparatus to be employed therein. (A communication.)

2114. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in obtaining and applying motive power. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, September 8, 1863.

1022. J. Cornes and J. C. Davis. Lawn mowing, rolling, and collecting machines.

1056. W. Hudson and C. Catlow. Looms.

1061. S. Crabtree. Balling motions.

1062. G. Hall and J. Wells. New explosive compound.

1069. T. Moore. Laying down, protecting, and controlling submarine cables.

1077. W. Tarr and E. Farr. Pianofortes.

1078. W. E. Gedge. Permanent advertisement. (A communication.)

1081. H. Worms. Elevating guns.

1082. M. Barland and E. H. C. Monckton. Withdrawing milk from cows and other mammiferæ. (Partly a communication.)

1087. J. Wibberley. Winding cotton, silk, wool, or other threads on spools or reels.

1093. J. Appleby. Propelling ships and barges.

1094. J. H. Johnson. Rotary engines. (A communication.)

1097. W. Clissold. Fulling woollen cloths and washing and cleansing woven fabrics.

1102. J. W. Gibson and W. Turner. Springs.

1104. J. Purley. Breech-loading firearms.

1105. S. J. Partlett. Straining and drawing off liquids.

1112. B. G. Sloper. Separating metals from earthy and other matters.

1115. J. H. Johnson. Manufacture of wrought iron and steel. (A communication.)

1138. J. Park. Communicating motion to machinery for manufacturing paper pulp.

1147. J. B. P. A. Thierry. Arrangement or construction of furnaces.

1154. J. H. Bailey. Mechanical movement for producing an impelled current of air for lamps, and which may be used for other purposes. (A communication.)

1156. W. Clark. Coating wrought or other iron to protect it from corrosion or oxidation. (A communication.)

1247. J. Beaumont. Condensing machines.

1273. F. P. Warren. Attaching copper or other sheathing to iron vessels.

1277. W. H. Clapp. Rail or holder for coats or other articles.

1293. E. Barlow, J. Ashworth, jun., J. Newhouse, F. Hamilton, and W. Hope. Lap machines for preparing cotton and other fibrous substances.

1360. V. Baker. Ordnance.

1420. J. G. Jones and R. Ridley. Apparatus for working coal and other mines.

1618. J. Chatterton. Lining iron and other tubes and hollow vessels.

1650. F. Ransome. Coating or preserving iron ships or vessels

1753. L. M. Bornique and J. B. Vidard. Railway carriages.

1754. L. M. Bournique and J. B. Vidard. Improved waggon or truck.

1857. P. E. Gay. Boring apparatus.

1968. P. M. del Rio. Obtaining motive power.

2012. E. B. Wilson. Blast furnaces.

2055. O. H. McCormick. Reaping machines.

2061. G. T. Bousfield. Feeding weft in hair cloth looms. (A communication.)

2069. J. Fleming. Preserving the colours of dyed fabrics.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed September 2, 1863.

640. J. Isherwood.
653. P. Hugon.

LONDON, FRIDAY, SEPTEMBER 18, 1863.

GUNS FOR THE NAVY.

THE present American war is distinguished by a series of the most important experiments in ordnance ever conducted—experiments the value of which cannot be over-estimated, because they are carried out under all the exigencies of practical warfare, and are in this respect infinitely superior to anything we have done at vast expense at Shoeburyness, and elsewhere in England. It is extremely unfortunate that all the reports we have of the performance of American guns are wanting in detail; and, although the main facts may be correct, we are unavoidably compelled to draw our deductions, in a great degree from analogy, in the absence of minute information. Nevertheless, we have at our command certain salient points, from which much valuable information may be derived, and many circumstances reach us with an amplitude, sufficient to entitle them to consideration as proved facts, calculated to guide us in our future proceedings.

Although both England and France have done much toward the introduction of heavy ordnance into their forts and navies, the goddess of peace has hitherto prevented us from practically testing the capabilities of guns intended to throw shot, ten or twenty of which would make up a ton. In America the case is different; and we find that the resources of the military engineer and the naval architect, have rendered a recourse to enormous ordnance all but indispensable; and compelled by practical difficulties to throw theory almost wholly overboard, the rival Governments have each distinguished the real value to be attached to range and accuracy, both as distinct from, and combined with, smashing effect and penetrative power. On land, rifled guns of long range and extreme accuracy are rightly deemed of the utmost value, and we find in consequence that American parks of artillery are usually distinguished by the presence of numerous guns, sufficiently like those of Whitworth and Armstrong to be regarded as nearly identical. None of these field-pieces are heavy, or intended to throw shot of any considerable weight; but, being well served, they have done tremendous execution at ranges which would be looked on as fabulous fifty years ago. A just appreciation of what was required from the "Monitors" and iron-clad steamboats, has secured to them an armament, the great characteristic of which is immense smashing power at a considerable range, without any great pretensions to accuracy. Our readers are too well acquainted with the performance of these guns to require any elaboration of the results at our hands.

Hitherto we have been unsuccessful in the introduction of any guns throwing shot much exceeding 100lb. weight. This arises from a misapprehension of the mission which very heavy ordnance is calculated to fulfil; from a faulty principle of construction following as a consequence; from defective materials, and imperfections in the mode of formation. In all these respects, our practice differs materially from that of the Americans. We attach little or no value even to a 200lb. gun if it be not rifled. The moment we obtain a smooth-bore of the kind, it is sent to the shops to be rifled—destroyed in consequence—pronounced a failure, and all large guns included in a sweeping condemnation. Our American friends, on the contrary, are content with the smooth-bore, well knowing that sharp rifling, heavy shot, and sufficient powder to attain a long range, are incompatible in the present state of the iron manufacture: hence their papers teem with reports the truth of which we see no reason to doubt, of the performance of 150lb. and 200lb. guns, spoken of, too, with a familiarity which shows that their use is, if not universal, at least general. It will be urged that the "Monitors" are armed with heavy rifled guns as well as smooth-bores; but we must remember that the American rifling is very different from ours—in fact, the system of grooving applied to most of their heavy cannon would scarcely be considered to deserve the name here, so slow is the twist.

It is extremely erroneous to conclude that all these guns are made of wrought iron. Even without the positive evidence on the subject placed at our command; we have the negative information, derived from our own failures, to prove that the manufacture of heavy guns from wrought iron is uncertain in the extreme. The American forges are certainly superior in no way to ours, in dealing with large masses of iron; and the Ordnance Department of the United States was so well impressed—as far back as the year 1841—with the importance of perfecting the manufacture of cast-iron guns, that able officers were appointed to every cannon foundry under contract with the Government, to conduct experiments, and see that all the resources of science and art were employed to produce the best possible ordnance. Some brands of American cast iron are infinitely superior to anything we can produce here. Inspection has increased the average strength of cast-iron cannon from 23,638 lb. to 37,774 lb. of transverse strain per square inch of section. The principle of re-melting is largely carried out, in some experiments the transverse strength of the iron having doubled by four meltings. This principle, combined with a careful admixture of different samples, and the exposure of the melted iron to a very intense heat for considerable periods, is found so far to improve its quality, that a sample was obtained at the Greenwood Foundry, N.Y., the density of which was 7·304, and its tensile strength 45,970 lb.! When we state that our best irons seldom exceed half this—23,000lb. being a high average—we are in a position to understand why cast-iron ordnance succeeds better in America than in Great Britain. Bronze guns are little used, except for the smallest pieces, its great expense and the uncertainty of the quality produced, condemning it for heavy ordnance. Major Wade's experiments in 1850 showed a difference in the density of various samples, taken from the same gun, equal to 20 lbs. to the cubic foot, the variation in tenacity being as 100 is to 236. A large proportion of the cast-iron ordnance is constructed on the "Rodman" principle. The guns are cast hollow round a central core, through which a stream of cold water, entering at the bottom, flows continuously, until the gun has become much cooled. Two 8-in. guns, cast the one hollow the other solid, were discharged repeatedly. The one cast solid burst at the 73rd fire, while the other withstood 1,500 rounds, and was pronounced practically indestructible with service charges. We have already stated that the heaviest guns used in the American Navy are, as a rule, either smooth-bores, or, if rifled, the grooves have an extremely moderate twist, the general principle of construction being to impart just such a velocity of rotation, and no more, to an elongated projectile, as will secure it from turning over in its flight. When the shot is made short in proportion to its diameter, very little suffices for this, and the gun is thus saved from the strain due to sharp rifling. The range is maintained with a smaller quantity of powder, and the accuracy of flight is preserved sufficiently for practical purposes. Range is imperially affected by the resistance of the atmosphere. The resisting surface area of the Armstrong shot is to the 68-lb. spherical projectile as 10 is to 50, while the expansive range of the powder is nearly 24 to 15. These are the conditions which secure range; to which rifling is really, in the abstract, inimical. Were it possible to discharge a conical shot, with a length of four or five diameters, from a smooth-bore, its range would be nearly double that of the Armstrong gun; and though this is to a certain extent impracticable, there is nothing, probably, to prevent the construction of a 100-lb. gun, which would pierce the "Warrior's" side at 1,200 yards, with a charge which even a good cast-iron gun might sustain many hundreds of times without injury. It would only be necessary to use a shot two or three diameters long, fitted so accurately as practically to prevent windage, while five or six grooves, making perhaps one-tenth of a turn in the length of the gun, would secure the end on flight of the projectile. It is very unlikely that such a gun would have sufficient accuracy to pick off a field officer at a range of a couple of miles, nor is there any reason that it should. We strain every nerve to supply our ships with arms of precision, forgetting that the conditions essential to the proper exercise of their powers can never be secured at sea. The officers on board the "Excellent," when experimenting on rifled guns by firing at a fixed mark, found "that there being no wind, and the tide keeping the vessel steady, they were sure of hitting it. Immediately the wind was a little too strong for the tide, and the vessel moved about; there was a considerable difference in the precision of the firing, although the water was as smooth as glass." Smooth seas and balmy breezes are rather the exception at sea, and neither Whitworth nor Armstrong would stand much chance of hitting a vessel even a mile off in a gale. The proper place for long range guns of great precision, is in the fort, the battering train, and the park of artillery. On board ship they are out of place, simply because we cannot avail ourselves of their real points of excellence. The 68-lb. is considered defective, because it wants range and accuracy. In smashing power it stands pre-eminent. The wisest course is to impart the advantages of a modified system of rifling to an arm which we cannot really dispense with; such guns would thus be rendered capable of discharging conical projectiles much higher, and better calculated for long flights than spherical 68-lb. shot, without any considerable sacrifice of initial velocity. Iron plates 4½ in. thick would prove a poor defence at even 1,000 yards from such ordnance.

The principal strain on the material composing a gun is indirectly due to the force required to overcome the *vis inertia* of the projectile. The power required to start a heavy shot into rapid motion, in a space of time inappreciably small, is something enormous, and would seem to imperatively dictate a recourse to some expedient, which will put the shot gradually in motion; several have been resorted to. In America, Eaton's gun has proved very successful. This gun, which is of considerable length, is loaded with a cartridge filled with an extremely slow-burning powder next the shot, the rest of the charge is made up of the quickest powder which can be obtained. The charge is ignited in front, thereby starting the shot into motion. A 6-lb., at 5 deg. elevation, has

thrown its shot 2,457 yds.; at 10 deg., 4,000 yds.; at 2 deg., 1,100 yds.

The armament of our Navy becomes, if possible, of more importance day by day. Ship guns will now have to perform work such as they never had to perform before. Field artillery requires little change. The same work has to be performed by it now which it accomplished fifty or one hundred years ago. It will have to be done at greater ranges, that is all. If we draw the proper distinctions between the services, we shall at once see the folly of sacrificing weight of shot and penetrative power to the attainment of a precision of fire, which, for its proper development, absolutely demands a fixed basis. In guns of great size, grooved just enough to secure the leisurely rotation of shot carefully made, and so fitted that windage is impossible, will be found the real weapon for the Navy. We have evidence before our eyes of the actual performance of such guns on the American continent. The lesson is too valuable to be suffered to slip from us unimproved. We search in vain for the record of any ordnance experiments which decide the minimum amount of twist, requisite to secure the proper rotative velocity of a projectile. We believe the day is not far distant when such knowledge will be invaluable, for on it depends in a great degree the success of all large guns. Without elongated shot, we cannot have range, or penetration at distances. Without rifling, we cannot use elongated shot. The heaviest ordnance has hitherto failed when rifled; and in the reconciliation of these apparent incompatibilities, will be found the most serious problem which the science of gunnery every presented. We believe its solution lies in so modifying the rifled system, that the communication of a moderate rate of rotation may no longer increase the resistance to the motion of a projectile through the bore of a gun, to such an excessive degree as to lead to its immediate or ultimate destruction.

BOILER EXPLOSIONS.

The professional attainments of the Astronomer Royal are sufficient to entitle his expressed opinions on scientific subjects to more than ordinary consideration. We regret extremely that the report of his Paper, read before the British Association, and placed by us a week or two ago in the hands of our readers, is so extremely meagre, that we must for the present, perforce, receive it in the light of a series of assertions, rather than as something more than a theory deduced from proved facts. We prefer, therefore, to suspend our judgment for the time, in the hope that valuable details of the experiments by which Mr. Airy has arrived at his conclusions may, ere long, be at our disposal. It is not wonderful, that, of all the remarkable phenomena which attend the application of the powers of nature to the arts, steam-boiler explosions should have met with most attention. Their frequent occurrence, their fatal and destructive results, and the mystery in which they are enwrapped, chained the attention of the philosopher, almost from the first introduction of the steam-engine; and our magazines, journals, and scientific literature generally, for the last 50 years, have contained more absurdities penned on this subject than on, perhaps, anything else in the circle of science.

It is not our intention to weary our readers by going over oft-trodden ground. One theory, and one only, is gradually making its way into general acceptation. This theory is so well expressed in a pamphlet on Steam-boiler Explosions,* published in 1860, that we simply reprint the paragraphs which contain it. Mr. Colburn astributes violent boiler explosions to—

1. The rupture, under hardly if any more than the ordinary working pressure of a defective portion of the shell of the boiler; a portion not much, if at all, below the water line.

2. The escape of the free steam from the steam-chamber, and the consequent removal of a considerable part of the pressure upon the water, before its contained heat can overcome its inertia and permit the disengagement of additional steam.

3. The projection of steam, combined as it necessarily must be with the water, with great velocity and through a greater or less space, upon the upper sides of the shell of the boiler, which is thus forced completely open, and perhaps broken in pieces.

4. The subsequent disengagement of a large quantity of steam from the heated water now no longer confined within the boiler, and the consequent projection of the already separated parts of the boiler to a greater or less distance.

When a theory is generally received as correct in the scientific world, we usually find very many claimants for the honour of its origination. The present is not an exceptional case, and we have gone with some care into a mass of conflicting evidence on the subject, simply with the desire that truth might be made apparent. Years ago, we find Harshman and others, contending that the violence of an explosion was due, indirectly, to the quantity of water contained in a boiler. Harshman's theory was however, simply absurd. He considered that some mysterious electrical action developed the "polar forces" (whatever they were?) in the water; and, rejecting all that science said on the relations between the water contained in a metallic generator, and electricity; floundered into a sea of doubt and uncertainty. Harshman was, however, an able expositor of the doctrines, nearly identical with his own, held by many others; and it is simply for that reason that we have singled him out from a number. The first rational exposition of the causation of an explosion—properly so called, and distinct from quiet rupture—is to be found in the pages of the *Engineer*, in the latter part of the year 1859. As Mr. Colburn has since identified himself with this exposition in the pamphlet we have quoted, we feel no hesitation in attributing to him the origination of the theory—that once rupture has commenced above the water line, "a great additional power is released, sufficient to complete the explosion and give it all the violence by which such explosions are usually characterized." The *Engineer* theory, however, went no further at that time, than stating that the percussive action of the large quantity of steam evolved from the heated water, was the proximate cause of that tearing and rending of the plates which usually takes place. Mr. D. K. Clark, in February, 1860, followed up Mr. Colburn's theory, and supplying the one item in which it was apparently defective, suggested, in a letter addressed to the Editor of the Mechanics' Magazine in that month, "that the sudden dispersion and projection of the water against the bounding surfaces of the boiler was the great cause of the violence of the results." Mr. Colburn deeming these views correct, incorporated them with his own theory, giving Mr. Clark, in his pamphlet, full credit for the suggestion; indeed, republishing Mr. Clark's letter from the Mechanics' Magazine; and thus the theory at present received is due to Mr. Colburn in the first place, and to Mr. Clark in the second.

Now, as we understand this theory, the propulsion of the water in masses of greater or less size against the upper plates, is supposed to take place; and that it is to the momentum of these masses that the destruction of the plates is due. If the theory is to be taken with this understanding, then we believe that Mr. Colburn's theory is injured, perhaps, rather than benefited by the addition of Mr. Clark's. Every atom of which the water contained in the boiler consists, equally repels its fellows, under the action of, so to speak, the atmosphere of heat which pervades the mass. On the sudden release of pressure, we cannot conceive why one portion of the water would be more readily converted into steam than another; and consequently—though we can conceive the dispersion of the water into a very fine mist—we cannot understand its propulsion anywhere in masses. We have performed some experiments on very small boilers, with flat unstayed heads of tin plate. These heads were invariably blown out bodily, and every drop of water dispersed; not so much in steam, as in a fine mist, which, ascending to a considerable distance, usually became absorbed by the atmosphere without descending again. We are strongly disposed to attribute this dispersion of the water *not to the production of interstitial steam, but to the direct action of the heat stored up within the water.* It is by no means improbable that very little steam, so called, is really produced in the first moment of an explosion, but it is not difficult to conceive that the particles of water, retained in union only by external pressure, may on its removal be violently forced asunder to a short distance—when compared with the state in which they exist in steam—yet with a force sufficient to account for the most violent results ever produced. If we take Joule's estimate of 772 foot-pounds as the equivalent of a unit of heat, and reflect that half a ton of coal is often consumed in raising the water to the working temperature, we can conceive the vast amount of power then stored up ready to be released in the thousandth part of a second. This store of power is nothing but a store of heat; and we know of no reason why the water may not be separated into the atoms of which it is composed with all the violence of a terrible explosion, without any necessity for its conversion into true steam.

Professor Airy states that one-eighth of the whole volume of a body of water was evaporated in lowering the temperature from 293 deg. to 212 deg. Now, if we suppose that the particles of the water evaporated were separated from each other to a distance, sufficient to produce an increase of volume 1,800-fold, there is nothing to prevent the separation of the particles composing the whole body of water to one-eighth of this distance with precisely the same mechanical effort. The water thus expanded would not be true steam, yet the expansion would be the result of the entire mechanical force of the heat stored within the water, and, being exerted in an inappreciable space of time, would produce the most tremendous effects in its expansion. The case would be precisely similar if we suppose the water within a boiler increased in volume, say, one hundred times. We can easily imagine the result.

* Steam-boiler Explosions. By Zerah Colburn. London: John Weale. 1860.

STAMP END IRON WORKS, LINCOLN.

The greater part of the skill, dexterity, and judgment with which the productive power of labour is anywhere directed or applied seem to have been the effects of the division of labour. Such are the words of Adam Smith, the apostle of free-trade, and the founder of the science of political economy. To illustrate this principle, that great thinker traced out the various stages in the manufacture of a common pin. He could scarcely have anticipated that—60 years after the publication of his "Wealth of Nations"—the manufacture of a particular form of the steam-engine could be chosen for a similar illustration. A walk through the

Stamp End Works would, however, convince any engineer that this great principle can be as completely carried out with an engine as with a common pin. It seems to be held by many that the chief advantage derived from a complete division of labour merely consists in the ordinary increase of skill to any man long employed at a special job. This increase of skill, however, does not confine itself to the operative, but also extends to the men at the head of the different departments, and of the business as a whole. Again, a variety of work—preventing the adoption of an organized routine—causes a great loss of time in passing from one job to another—a loss of time, indeed, the amount of which, though great, it is impossible to ascertain from the books. On the other hand, numerous special machines can be profitably constructed and employed to manufacture details of which there is a repetition; and these special tools not merely lighten and shorten labour, but also greatly improve the quality and accuracy of the work. Instead of a skilled workman labouring at a great expense of skill and exertion, an unskilled operative merely directs the execution of the job; one man thus does the work of many; and indeed, most machines of this kind can be pointed out as being in themselves the sources of large incomes to the proprietors. The mere fact that a firm is able to devote its undivided attention to one or two classes of work is of itself an indication of special and general progress—special, as it is a universal suffrage vote for the quality of the articles delivered—general, as the division of labour is always the attendant of a high civilization; a pretension to universal science and ability was only acknowledged in the dark ages; while England herself is the country *par excellence* where the division of labour is the most completely carried out.

There are few manufacturing engineers so fortunate as to get a complete repetition of work—that *summum bonum* of the manufacturer—the sure road to fame and wealth—the only means of combining cheapness with good work. The Stamp End establishment, however, is able to almost entirely confine itself to the manufacture of portable engines and thrashing machines. Now there is no other form of the steam-engine, in the manufacture of which the division of labour can be so fully carried out as with portables. The locomotive, for instance, the elder brother of the portable engine, is not, numerically, in such demand. It is also seldom that an exactly similar type of locomotive is required in large numbers in succession. Orders are not often given out for more than a dozen similar locomotives at the same time. Such exceptions as the 50 locomotives manufactured some time ago at the Atlas Works, Manchester, are few and far between. When one of these exceptions does occur, and if a fair price be given, a fortune can be made by such an order, as the fruitful principle of the division of labour can then be carried out to its fullest extent. Towards the immense number of portable engines in use in different parts of the world—10,000 of which are estimated to be in use in England alone—the Stamp End Works have contributed, up to the end of last August, no less than 5,395 fixed and portable engines. It has been questioned by some people whether this establishment has really turned out such an astonishing number of engines, and in so short a time. Now, by special favour, we have been furnished with authentic proofs of the matter. Every engine, as it leaves the shop, receives a number, and this number is carefully registered in a book, together with the name of the customer, and all the particulars of the engines, such as the position of the tubes, and, in fact, an account characterising every working part. In case it be wanted to repair one of the 5,395 engines—and any engine, however well made, must be repaired at some time or other—the makers, on being simply furnished with its number, can instantly identify the engine; the detail ordered is at once sent to any part of the world where it may be required; and it can be at once applied to the engine in want of repair. This complete system for quickly and cheaply effecting repairs would be a point in favour of the Stamp End engines, even if they were not of a superior shape to most of the other engines in the market. Several unprincipled small makers completely copy the Stamp End engine, even to the smallest split-pin; and coolly state that "their engines are exactly like Clayton and Shuttleworth's." We doubt, however, whether any of these servile imitators have such a system for repairing their copied products. To those interested in agricultural statistics, the following table we compiled from the books, with the dates and numbers of the engines delivered each year, may be valuable. The largest engines made are those of 20-horse power; the smallest of 3-horse power, nominal:—

DATE.	NUMBER.	HORSE-POWER.
1845	1	8
1846	2	16
1847	8	73
1848	15	87
1849	55	316
1850	74	420
1851	126	611
1852	209	1153
1853	282	1608
1854	389	2117
1855	445	3074
1856	507	3611
1857	423	3174
1858	378	2837
1859	514	3941
1860	533	4075
1861	566	4409
1862	543	4276

Up to the end of last month 395 engines were made in the year 1863. Last week—the week ending August 29th, 1863—16 new and 2 old engines were turned out of the works. Of thrashing machines, 13 new and 3 old ones were delivered. Four straw elevators (Hayes), 3 flour-dressing machines, and 5 corn-mills were also completed. From 60 to 70 engines, and as many thrashing machines, are generally in the store-shop waiting for delivery. It is noticeable that the average size of portable engine now sold is 8-horse power; in 1855, 6-horse power, and in 1851, 5-horse power engines were most in demand. The call for 10-horse power engines is evidently due to the general adoption of steam cultivation, to which these engines can be easily applied. The manufacture of thrashing machines has advanced in a nearly parallel line to that of the engines. Last year they sold about 500 thrashing machines, making up a total of 4,500 Engines and thrashers form the staple of the Stamp End trade, but portable corn mills—the first of which was made in 1846—are also manufactured.

It will be seen by the above table that the importance of these works dates from what is a very short period in the life of an engineering establishment. Messrs. Clayton and Shuttleworth began manufacturing on an extremely small scale in 1842; in 1849, only fourteen years ago, they exhibited their first portable engine and thrasher at the Royal Agricultural Show at Norwich. From the year 1852, only ten years ago, did their establishment assume somewhat of its present position, and now they are the largest makers in the whole world of engines and thrashers, with off-shoot establishments at Vienna and Perth, and with extensive agencies in every civilized country. The excellent show made by this firm at the great Exhibition of 1851 added greatly to their prosperity. The sound character of the Stamp End workmanship became known to the public; its quality was recognised by the jurors of the Exhibition of 1851, and the firm received two medals for their engines. In common with most of the other exhibitors last year, two of the indiscriminately distributed medals also fell to the lot of the Stamp End firm. Marks of distinction in which so many thousands participated could not be of much value. We may, however, state that such engineers as Mr. Humphries, Mr. Penn, and Mr. Maudslay have testified their approval of the Stamp End make of engine—as exemplified in the engines they saw at South Kensington—by lately sending several orders to Lincoln. The neat little Stamp End engines are now doing duty in all parts of the world; they have thrashed out this year's corn, not merely in the happy homesteads of England, but also in the steppes of Russia, the *puztas* of Hungary, the Canadian prairies, and in the Australian bush. . . .

However much a man may feel bent to ascribe the prosperity of any undertaking of this kind to good luck, it is impossible for an engineer to stroll through these works without seeing that other causes besides have helped to bring forth this unexampled success. In the first place, the situation of the works is exceedingly well chosen. Placed in the centre of an agricultural district, and, at the same time, not too far from the principal manufacturing towns, the position of the establishment must have greatly forwarded its progress—particularly in the earlier stages of its career. The workshops are only a few yards from the Great Northern Railway, and the Manchester, Sheffield, and Lincolnshire line skirts round a great portion of the works. Branches from these two lines run right into the yard, and the line of rails is continued so as to give a complete communication between all parts of the works. A canal from the river Witham, at which point that river begins to be navigable, almost divides the place in two, and there is thus a complete railway and canal communication. The ground upon which the works are built was at one time the estuary of the river Witham; and this former swamp had to be drained and raised up 7 ft. by the addition of materials before the buildings could be erected. The entire area occupied by the works is rather more than 9 acres. The finished engines and machines are packed on the railway trucks from a high platform inclined towards the works—a plan by which the labour of several horses is economized. The different shops are very large and lofty, and are all lighted from the roof. This is the only way to efficiently light up workshops, as in the absence of skylights, the space in the middle is more or less lost. The principal offices are built in a style of absolute magnificence; the building looks more like a nobleman's mansion than a house built for the transaction of the business of a private firm. There are quite large gas-works on the ground, manufacturing 150,000 ft. of gas per week during the six months of the winter season. Nearly 1,000 operatives are employed in all, and with the addition of the clerks and the other officials, the total number of people engaged probably exceeds 1,000. The machines and tools are driven by stationary engines of 120 collective nominal horse power. For several years this establishment has been constantly "making overtime," up to 8 or

half-past 8 o'clock, and sometimes later, so that in reality the actual amount of work work turned out is greater than would be represented by the above number of men. We noticed that the beneficial institution of the Saturday half-holiday was introduced into these works—the men knocking off work at half-past 12 o'clock on that day.

Without attempting to give an exact account of the relative positions of the different workshops—a thing difficult to make clear without a ground-plan—we may state that, with the partiality of an engineer, we first examined the turning, fitting, and erecting shops, in which the fixed and portable engines are manufactured. Now we have been enabled at various times to inspect almost all the first-class shops of England, France, and Germany; but we may confidently state that we have never seen an engine manufactory with such complete arrangements for perfectly doing every detail by means of machine tools alone. Absolutely all the work—of, for instance, the engine connecting-rods—is done by machinery; the file is only used to take the slight burr or "arrage" off the edges of the straps and brasses. After carefully examining a finished connecting-rod we took at haphazard amongst a number in the store, we can state that it was a first-rate piece of fitting, and done entirely without the use of a file. The heads and straps are slotted and shaped; the cottar holes are done in a slot drill; the semi-cylindrical edge of the cottars themselves are shaped in a peculiarly ingenious lathe (by Smith, Beacock, and Tannet)—all the parts being made to case-hardened templets. The bright surfaces are not even draw-filed; in fact, they do not require it. We believe that the Master Workman of England—Mr. Whitworth—was the first to so completely dispense with the file. The eccentric-straps are made in a peculiarly advantageous way as regards exactitude and speed. The two halves are cast together, and turned up, then slotted in two, leaving a small space to be filled up by a packing piece for taking up the wear. The outsides of the eccentric clips are shaped in a kind of filing machine, in appearance like a small slotting tool, but fitted with a rough species of file, working up and down. The work is slightly drawn back by the machine during the return stroke of the tool. The system for finishing the cylinders is also excellent. The cylinders for double-cylinder engines are always in one casting, and the regulator valve is also cast on, thus doing away with unnecessary joints. These double cylinders are bored out on a specially-made boring lathe; the casting being fixed on a cross-slide, traversing parallel to the face plate. After one cylinder is bored out, the second can be immediately adjusted by merely sliding it across up to its centre. Both the single and double cylinders are first of all bored out in a very neat horizontal boring lathe, made by the firm itself. After being fixed on two special brackets with cones (clamped to the flanges), the valve-faces are planed out in a machine. The faces of the cylinder flanges are then turned up true in a lathe. Any mechanic can see that this system must make an accurate job, and without much expense. Not even the *contours* of the cylinder flanges are chipped; they are slotted out in a slotting machine with two tools. The top tool cuts during the downward motion, and the second tool below slots out the flange at the other end of the cylinder during the up-stroke of the machine. Any burr, or slight tear, is thus towards the inside of the cylinder, and the exterior of the flange then merely requires to be draw-filed. In common with all the other details which have to be fitted to the outside of the boiler, the bottoms of the cylinders are carefully planed to the arc of the outside of the boiler-shell. The work is fixed on the bed of a planing machine, the tool of which is made to travel radially in a portion of a circle of the same diameter as the boiler. All chipping is thus done away with, and what is a most expensive job by hand is done by a machine. The planing machine is made to do this job by means of a contrivance uniting simplicity and efficiency in a degree that amounts to a stroke of genius. The tool-box is attached to a bar above, swinging in a centre like a pendulum. The tool-box—fed horizontally along the cross-slide of the machine in the usual way—is constrained to gradually traverse in the arc of a circle determined by the length of the attachment of the bar from the centre pin above. The various lengths of the bar are adjusted in a vertical slide at the top. The stuffing-box glands are slotted out in a machine, while being exactly traversed underneath by means of a contrivance similar to that of a copying lathe. The slide bars are accurately drilled and fitted to a special bracket. The use of special brackets and chucks for drilling, tapping, turning, and planing is a most efficient means of obtaining good and cheap workmanship; it is a means too much neglected in some quarters. All the machine and engine cranks, as they are turned in the lathe, run in an eccentric steadying head; any jar is thus prevented. We noticed a very fine lathe—made in Leeds to a special order of the firm—of such a size that a 12 ft. fly-wheel could be fixed, and turned up on the face plate. The shafting of the turning and tools, and other straps is carried in a remarkably efficient, elegant, and, as we think, original manner. The main shaft is supported on a bearing in the centre and on the top of a handsome column. The counter shafts on each side of the column are supported on arms, carrying a wooden plank in the usual way. When we say that these columns are elegantly shaped, we do not mean that they are furnished with vulgar and hideous ornaments (!) like the large pillar, for instance, supporting some gas lights in front of King's Cross station. We mean that they are formed with neat and flowing lines, and without any of those abrupt breaks in the continuity of outline, so displeasing to any one cursed with good taste. In this part of the works, we counted 60 lathes, 9 slotting, 9 screwing, and 10 shaping machines, as also 20 drilling and 7 boring machines, 3 planing and 3 nut-shaping machines, besides one wheel cutting, one filing, one centering machine, and several other tools. All the working drawings are varnished, stretched on frames, and carefully kept in a particular store furnished with a long rack. Each drawing is numbered, and has its own particular place in company with its companion detail drawings of the same class of engine. The two turning shops are each 110 ft. by 56 ft., with galleries for the fitters. About 120 turners and 140 fitters are employed in this part of the works. The engines being put together in the erecting shop, are shifted about by means of a powerful travelling crane. Every engine, on being finished, is carefully tested on the friction brake. This is not merely the case with the portable engines—five of which are generally tried at a time under a shed—but also with all the fixed engines. The latter are adjusted on a strong wooden framing, placed under the steam-pipe feeding one of the shop engines—a connection being formed with the engine to be tested by means of some gas-piping. The work of the erectors is thus subjected to a thorough practical test, before leaving the shop. We do not believe that this complete system of testing the work is adopted at any other agricultural engineering establishment in England. Judging by the number of men employed, the coal burnt, the oil consumed, and the expense of the general arrangements for testing the engines, we should say that Messrs. Clayton and Shuttleworth spend at least £2,000 per annum in this department. When engines are erected by piece-work, such a system is the only means of obtaining a complete check over the men. We noticed, among the engines over the testing pits, a portable one for irrigating some of the cotton districts in Egypt. Two force-pumps were worked by a double crank shaft parallel to the axis of the boiler. The engine could be easily adjusted for ordinary purposes by disconnecting the gearing driving the crank-shaft of the pumps. Several portable engines working Appold's centrifugal pump are also being constructed for irrigating some land for the Pasha of Egypt.

The large smithy is a very fine shop, 180 ft. by 80 ft., and lighted from the top. About 100 smiths are now working overtime at 56 fires in all. The hearths are not provided with the usual iron hoods now so fashionable—a happy thing for the men during the hot summer of this year. Brick hoods, of course, do not radiate the heat so much as those of iron. It has sometimes occurred to us that the ordinary plate-iron hood might be turned back and partially filled with water, in order to prevent the usual radiation of heat so uncomfortable to the men. The perfect organization of the machine tools enables a complete adoption of the modern system of forging in blocks; thus reducing the expense of the smith's-work, while leaving more to the cheaper work of the machine tools. The engine cross-heads are thus first forged in the shape of a simple cube; then slotted out, and finished, on a special chuck, in the lathe. Four steam-hammers were at full work.

We were greeted with the usual din on entering the boiler shop—a noise, as is well known, literally deafening in its effects on all old boiler-makers. We counted 2 plate-bending machines, 4 drills, and 4 punching and shearing machines in this shop. One of Garforth's steam-rivetting machines is in full work, for rivetting up the flues and shells of stationary boilers and the barrels of portable engines. Perhaps, in course of time, some enterprising tool-maker may make a machine capable of closing every rivet in a boiler; and the dull thud of the steam-rivetter will then supersede the noisy clatter of the hammer. During the erection of the high tower for the reception of the crane holding the flues up to the rivetting machine, a man, now at work in Lincoln, actually fell from the top to the bottom—a distance of more than 50 ft.—with scarcely any injury. He fortunately alighted on a soft part of his body, which thus—buffer-like—broke the fall. Some flush boilers were being made for traction engines. We were informed that the firm lately constructed several fire-boxes of steel, which they had to replace with fresh ones of iron. The steel was found too brittle, especially at the tube plates.

The iron foundry is a large shop, 106 ft. by 75 ft.; with two five-ton cupolas; casting enough iron from 100 moulders (men and boys). Only twelve pattern-makers are employed—a strong testimony to the demand for the well-known staple productions of the works. The six cranes are all fixed against the two opposite walls. It is worthy of note that a particular mixture of different irons is melted for the cylinders; being run into pigs and used as required. This is the only way to get a good silver-like metal for a cylinder, and it is a plan also adopted at the Gorton foundry, Man-

chester. There are also a brass foundry and a malleable iron foundry. The malleable castings are cast from common metal; but are then baked in a material appearing to be principally composed of hematite iron ore. The entire operation lasts from five to six days, and the castings are kept a portion of the time at a dull white heat. They are then cleaned in a machine similar to those used for taking the rust off scrap iron. Clayton and Shuttleworth were the first to make Goucher's beater of malleable cast iron—the inventor himself having used an impracticable arrangement, consisting of a bar wound round with wire.

The manufacture of thrashing machines has quite distinct features from those of engine-making. It requires more special skill, and a thrasher is a more complicated machine. Almost any petty engine-maker can fit up a small engine, which will do its work in a tolerable way, even if it does show a voracious appetite for coals. The experience required to make a good thrashing machines, is undoubtedly more uncommon. We believe it to be generally acknowledged that Messrs. Clayton and Shuttleworth turned out the first really practical thrashing machine. The division of labour and the employment of special machinery is carried out almost as completely with these wooden machines as with the iron engines. A very complete collection of wood-working machines are in full employment. In fact, almost all the woodwork details are done by machinery; hand labour being of course employed to erect the machines. Two of Messrs. Greenwood and Batley's copying lathes cut out the whippletrees, shafts, and wheel-spokes for the thrashing machines. Another machine shapes out the cylindrical ends of the spokes. We also noticed a band-saw, a planing machine with a horizontal spindle, a planing machine with vertical cutters, and several other wood-tools; all from Messrs. Worssam, of Chelsea. A table, fitted with vertical revolving cutters, is used for shaping and boring out the felloes of the wooden wheels. The thrashing machine erecting shop is 40 ft. wide by 320 ft. long, and 200 "machine wrights" are therein employed. Fourteen machines were being made. A large collection of oak and teak for the framing, and of ash and other wood, is kept in seasoning for years before being used. The value of the timber thus stored is estimated at several thousand pounds. A great number of Hayes's straw elevators are made by the firm. Hayes's elevator consists essentially in a large wooden trough, about 4 ft. 6 in. wide, traversed by an endless band armed with iron spikes, carrying off the straw as it leaves the shakers of the thrasher. Campain's straw elevators are also occasionally made. More than a thousand thrashers have been already here fitted with Bruckshaw and Underhill's elevator. The firm has introduced an additional small fan to the delivery tube of this apparatus, in order to aid the cleaning action of the elevator blast. Clayton and Shuttleworth are the proprietors of "Coulson's patent hangers"—consisting of ashen springs, to which are suspended the reciprocating parts, such as the riddles. Experiments with steel suspension rods, attempted to be used for the same purpose, were at the outset tolerably successful; but the first frost caused them to snap. Coulson's ashen springs are also used to communicate motion to the riddle. We noticed the new beater now used by this firm instead of Goucher's. The beater plates are grooved with lines running in a direction parallel, and at a pretty quick angle, to the axis of the beater. Many of the thrashing machines are sent out with gutta-percha bands, furnished by the Company of that name.

Several new workshops are in course of construction—namely, a shop for lagging and painting the engines, and another for painting the thrashers. A covered station is also being built over the branch line from the Great Northern.

In conclusion, we may express a hope that our readers will have derived from the above imperfect account, some of the pleasure we experienced during our stroll through these well-arranged works; a pleasure greatly heightened by the courtesy with which we were received by everybody—from Mr. Joseph Shuttleworth himself (the managing partner), to the humblest labourer.

AMERICAN TORPEDOES.

Some days since, says the *New York Herald*, the enemy made a systematic effort to blow up and destroy the gunboats and transports in Stono Inlet by means of torpedoes. Fortunately, no serious damage was inflicted upon any of the vessels by these infernal machines of destruction; but the escape was quite narrow enough for comfort. One torpedo exploded a little astern of the "Pawnee," and blew her launch, which was towing astern, to fragments. A few moments later a tremendous explosion occurred on Bird Key, a few rods below the "Pawnee," occasioned by another torpedo sent down at the same time. From facts since developed, it is certain that the rebels sent down on that night at least ten of these inventions of the devil, three or four of which exploded, and four of which were picked up. One drifted through the fleet of transports and up the Folly River, and exploded under the bows of the mortar schooner "C. P. Williams," but occasioned no damage. The torpedoes are precisely like those we have found in the Light House Creek, and go off at the slightest concussion. The method adopted in sending them down and securing results is rather ingenious. The boat picked up in the Stono the day after the explosions occurred was fitted up for torpedo business. It had a long and wide plank fastened across the gunwales, upon which the torpedoes were placed. From certain marks upon the plank it was evident that ten of the machines had rested upon it. The torpedoes are launched upon an ebb tide and sent down in pairs, connected by a rope 50 ft. or 60 ft. long. On each of the machines a rudder is attached —one fastened hard a-port, the other hard a-starboard. By this means the bows of the torpedoes have a tendency to move on divergent courses, and the line is straightened out. As they float down the tide, the anchor chain of the vessel which is to be destroyed, catches the rope about in the middle, and the torpedoes are borne down the current to the length of their cable, when they swing around and strike the side of the vessel. The concussion explodes them, and the natural consequences attending the explosion of 80 lb. of powder under a vessel follow. They did not work in the instance referred to, but they may yet do damage. Precautions have been adopted to prevent any serious damage to the vessels from further visits of those devilish inventions of the enemy.

THE COMBINATION SYSTEM OF SHIP-BUILDING.

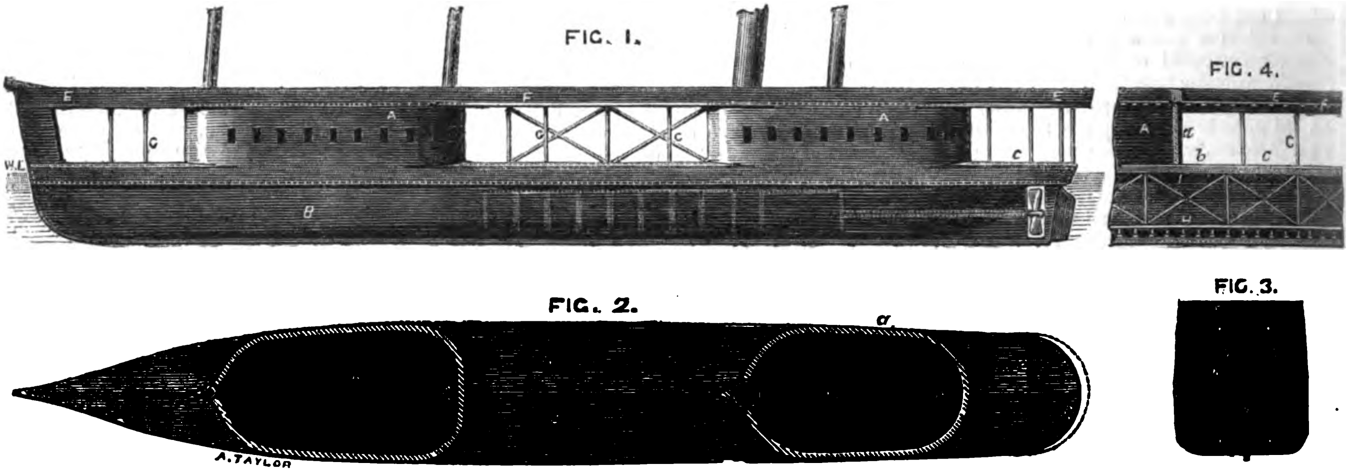
Shipbuilding in this district, says the *Newcastle Chronicle*, has reached of late a new phase in its progress—an attempt to secure all the advantages of wood and iron by combining these two materials in the construction of merchant vessels. This system, though practised in the Thames, the Clyde, and the Mersey, is comparatively new to this district, for, if we mistake not, Sunderland is the only one of our northern shipbuilding ports where it has been brought into practical use. It is somewhat to be regretted that the shipbuilders of the Wear took no pains to bring this subject before one of the sections of the British Association, with a view to discussion and comment. Although a proportion of "the wise" who went over to Sunderland had an opportunity of inspecting vessels built on this principle, the bulk of our learned visitors had not the opportunity; and therefore, we may be excused the reproduction in these columns of some account of the system.

It was first introduced on the Wear by Messrs. G. S. Moore and Co., and afterwards adopted by Mr. Peverell, those two firms continuing to build exclusively on the combination principle. Mr. James Laing and other builders of iron vessels, who possess the necessary machinery, also build on this principle when required. As to the mode of construction, we take the description of Mr. Moore's plan, which is this:—The keel is of wood, and laid in the usual manner, while the stem and sternpost, also of wood, are fastened thereto, precisely as in a wood-built ship. The framework is of iron, like that of an ordinary iron-built ship, and its component "ribs" are all rivetted into an iron plate on the keel. This plate is of sufficient width to take in the garboard strakes, which are bolted through the keel, and also through the plate and frame. To secure greater strength for this framework of iron, it is trussed on the outside with flat iron bars, extending from the keel plate to the sheer strake, these bars being placed diagonally, 5 or 6 ft. apart, and rivetted to each frame. The beams are also of iron, fitted in their places, and secured to the frames by stringer plates and angle iron. A strong and rigid skeleton of iron having been thus produced, the next operation is to clothe it with a waterproof skin that will best enable the ship to resist the power of the element in which she finds her future home. The combination builders eschew, for various reasons, the system of iron-plating, and adopt the planking of teak or other wood, half an inch thicker than the thickness required by Lloyd's for a wood-built ship. This planking is fitted to the framework and diagonal trussing, and secured to the frames by bolts of yellow metal driven from the inside, and clenched upon rings of the same metal upon the outside plank. The vessel can be then coppered to prevent fouling, and finished in the style of ordinary timber-built vessels.

The great lightness and buoyancy secured by this mode of construction, as well as the economy of internal space by the substitution of iron for the thick and massive framework of timber-built ships, must be evident to every one. The corrosive action of moisture in this combination of wood and iron, which at first formed a difficulty in the way of combination building, is now entirely obviated by coating the iron and leaving the framework, internally, quite uncovered. Thus a free current of air passes over it continually, and it can be painted as often as necessary to ward off oxidation. The more serious difficulty of galvanic action between the copper fastenings and the iron of the framework, has also been overcome by the plan patented by Messrs. Moore. Each copper bolt is furnished with a collar of an incorrodible composition. This capsule being then soldered to the collar, the bolt becomes hermetically sealed, and safe from external action. The adoption of iron framework also relieves the shipowner from the dread that dry-rot may attack the internal timbers, and the shipbuilder from the difficulty, so frequently experienced, of obtaining good beams for first-class ships and crooked timber for frames. Moreover, there is no shape, or curve, or angle, that iron framework may not very easily be made to assume.

The disadvantages of timber-built ships are, the frequent liability of the frame-timber to rot, and consequent great expense of repairs, and the loss of internal space for cargo through the thickness of the timber in the vessel's framework. The undoubted value and advantages of iron ships are counterbalanced somewhat by their liability to internal oxidation, and by the infinitely greater obstacle presented by the fouling of the bottoms which obviates the fast-sailing properties which they would otherwise possess. An advantage in all these respects is claimed by the combination system. Objectors may doubtless be able to point out defects and weak points, but the great question is, which of the three systems can claim to possess the fewest of these; The recognition which the combination system has already received, augurs well for its more extensive adoption when it becomes better known and its merits are inquired into. The fact of its including the internal economy of space—the great advantage of iron ships, and avoiding by means of copper sheathing their great defect, are important points in favour of combination. There is no doubt combination ships will be much valued until the prevention of fouling on iron hulls can be accomplished, for it is well known that an iron steamer which has been a short time at sea cannot cope in point of speed, with copper-bottomed wood vessels such as the "Alabama." Rapidity of construction, and the fact that the planking can be as easily caulked and repaired as that of wood ships, are further advantages claimed for the new system; while combination ships are also said to hold together better when stranded, and thus afford to sailors and passengers a greater security of life than iron ships which (as in the case of the "Royal Charter") break up rapidly.

CLARK'S ARMOUR-PLATED SHIPS.



CLARK'S IMPROVEMENTS IN ARMOUR-PLATED SHIPS.

The following improvements in armour-plated ships have been recently patented by Mr. W. Clark, engineer, London:—According to this invention, war-ships are built having the main body or continuous part of the hull but little above the load line, say, some 3 ft. or 4 ft., or it may be only to the load line; so far the mould of the ship is much as in ordinary; from this level the hull of the ship is carried up in sections, say, in two sections or parts (for a ship 400 ft. in length) of about 100 ft. each in length, the one part commencing, say, some 30 ft. or 40 ft. from the stem, and the other about 20 ft. from the stern. The part of the lower body unoccupied by these raised sections or structures will be a kind of deck, which is covered over with strong iron plates to give the necessary strength to the hull and to resist the force of exploded shells or the graze of shot, to which alone it would be subject, being nearly or quite horizontal. In building these vessels a light upper deck may be carried over the entire area of the ship, which deck is carried between the raised parts of the hull on girders stretched from the one to the other, and if necessary supported by pillars from the exposed plated deck below. Besides covering the raised parts of the hull with armour plates, the patentee covers the main body from end to end with armour plates, say, to the required depth of 5 ft. below the water line and over the whole of the lower part of the hull rising above water, which may be to the extent of 2 ft., 3 ft., 4 ft., or even 5 ft. For a ship of five or six thousand tons burden a saving in the weight of armour-plate to the extent of some 400 to 500 tons will be effected. The high parts of the sides are alone pierced for guns.

Fig. 1 represents, in side view, an armour-plated ship constructed with the upper and flush deck.

In this illustration are represented two gun-chambers A, as rising up from the lower part of the hull B, B, but their number is not imperative, and they may be otherwise disposed—that is to say, they may be further forward or aft, or of larger or smaller dimensions. If greater buoyancy is required at the bow, for instance, it may be advisable to place the fore chamber farther forward, or it may be better still to enclose the forward open part of the ship, but which it is preferred to do in light framing and plates easily penetrable by shot and shell, from the effects of which the ship would be protected by her plating.

Between the part B and the gun-chamber the upper deck E is supported on girders F and pillars G, as also between and aft of the gun-chambers; these may be further strengthened by longitudinal and transverse diagonal stays, as seen in the side view and cross section. The gun-chambers A may, of course, be pierced for a greater or lesser number of guns, according to the capacity or requirements. The rudder-head entering the vessel below the water line will require to enter through the stuffing-box, and may be worked below the open deck C, or the steering gear may be carried forward and up to the upper deck E, within the after gun-chamber. Fig. 3 represents a midship section of fig. 2, and fig. 4 a partial longitudinal central section of the same.

In order to prevent the sea washing over the upper deck, it may be necessary to carry the deck much higher from the water line (say 25 ft. or 30 ft.) than in ordinary ships, but for which this form and construction of ship will be readily capable, as having less weight above the water line, and being less subject to rolling motion than vessels of an ordinary build.

LOCKING-UP FORMS OF TYPES.

The following improvements in printers' chases have been recently patented by Mr. Robert Ward, of Newcastle-on-Tyne. The invention has for its object improvements in locking-up or fastening forms of type or other printing surfaces. For these purposes, in place of employing loose wooden wedges acting on side-sticks or foot-sticks, as heretofore, a long wedge of any suitable material, by preference in one piece, but this is not essential, is placed between two foot-sticks or two side-sticks, and such wedge is set up by a screw, which is formed with a head having holes therein by which it can be readily turned whilst in the chase, in which the "form" of type or printing surfaces is required to be locked-up or fastened. The head or outer end of the screw rests against a block, whilst the screw itself enters a female screw formed in the larger end of the wedge; hence, when the screw is turned, it will force the wedge more and more in between the two foot-sticks or the two side-sticks so as to cause them to separate, and thus lock-up or fasten the "form" in the chase.

BRITISH ASSOCIATION.

Mathematical and Physical Science.

LADD'S ELECTRO-MOTIVE ENGINE.

The electro-motive machine exhibited and described by Mr. Ladd consisted of two coils forming a powerful electro-magnet, revolving on an axis parallel to the axes of these coils, and at equal distances between them. On the stand, four pillars, forming coils, were planted in the circumference of a circle round the revolving electro-magnet, and at such a distance from it as to permit its free motion. By a simple contrivance, similar to the commutator, the electric current was so transmitted and reversed as to make each of the pillar coils a magnet, with the pole it presented to that of the revolving coil as it approached it, of the opposite name, south or north, but the instant it passed, reversing it into one of the same name; thus, while advancing, it is attracted, but, the instant it begins to retire, repelled; and so a constant motive force is applied to keep it revolving. The engine exhibited was mounted with bevel wheels, carrying an axle, on which a cord could wind up a weight of some pounds. It was also furnished with a friction brake, by which its power, which was, even with only two Grove's cells, considerable, could be exactly measured.

ON THE ELECTRICAL RESISTANCE AND THE ELECTRIFICATION OF GUTTA PERCHA AND INDIA RUBBER UNDER VARYING PRESSURES, EXTENDING TO 300 ATMOSPHERES,

By Mr. C. W. Siemens.

The pressures were produced by a powerful hydraulic press. Mr. Siemens found, by experiment, the resistance of gutta percha, or, in popular language, its insulating power, increased as the pressure increased, and the rate of increase was found to be greater the higher the pressure. At 300 atmospheres the resistance was nearly three times that observed at atmospheric pressure. When the pressure was removed, the resistance immediately fell to nearly its original amount, and, after some time, regained the original resistance exactly. The resistance of india rubber, on the contrary, was found to decrease with an increase of pressure, but the rate of decrease tended to become constant; when the pressure was removed, a kind of rebound occurred, for the resistance immediately rose to more than its original amount, but, after some time, again fell to its first condition. It might be thought that this effect in india rubber was due to the introduction of water into its mass under high pressure, whereas gutta percha might be supposed to resist this kind of percolation. This view was, however, shown to be untenable; since, when a wire was first covered with india rubber and then with gutta percha, the change of resistance due to the increase of pressure was a mean between the results obtained with gutta percha and india rubber separately. The effect on the apparent resistance of the insulators by continued electrification, first published by Mr. Fleeming Jenkin at the Aberdeen Meeting of the Association, was next alluded to. Mr. Jenkin found that the decrease of the current passing through the gutta percha, due to electrification, was constant at all temperatures, and independent of the change of resistance due to this cause. Mr. Siemens had found the same result with the change of resistance due to change of pressure.

DAWES'S SOLAR EYE-PIECE.

Communicated and exhibited by Dr. Lee.

Mr. Dawes has introduced his admirable solar eye-piece, which possesses the advantage of being applicable to any existing telescope. The solar phenomena are, therefore, more within our ken than formerly as to their shape and habits, or successive changes, and particularly as to their effects; but their physical constitution remains unfathomable, like the question, Whence come the perpetual beams of light and heat of the orb itself? Yet these particulars, the theme of endless plausible cogitations and ingenious suggestions without proof, though still among the unrevealed mysteries of nature, may finally submit to unremitting researches. For instance, the solar spots can now be safely pro-

nounced to be no longer an object of idle curiosity, like the casual clouds of our atmosphere. The few landmarks hitherto recorded begin to indicate a regular progress of position in them, with periodical maxima and minima in their amount. Thus, in the years 1845-46, the groups of solar spots extended to about 40 deg. north of the Equator, and to 30 deg. [illegible] it, leaving a central blank band from 8 deg. [illegible] 5 deg. south. This state of arrangement is [illegible], with the exception that the prepon-[illegible] present on the south side of the [illegible] in 1853 and 1854, the spots were distri-[illegible] deg. north to about 20 deg. south, de-[illegible] till early in the year 1856, when [illegible] minimum, and the equatorial [illegible] clear; but spots appeared in both [illegible] 20 deg. to 40 deg. Their parallels are [illegible] contracting. So much for their [illegible] for their *motion*. Their daily drift in [illegible] a general equatorial current 30 [illegible], in the direction of the rotation, and [illegible] of nearly the same breadth is [illegible] beyond it, in each hemisphere. In the [illegible] we are greatly indebted to Mr. Ca[illegible]; but now we must turn to Major-[illegible] Sabine, with thanks for the light that he has shed on the mysterious correspondence between the solar and the terrestrial magnetic disturbances; for a decennial period is therein indicated, as well as another connected with the earth's orbit, which brings us to the present wondrous result of well-directed investigation. Every inquiry which leads to our information respecting the physical condition of the great centre of our system is of the highest scientific value; and as there is some danger to the eye in closely watching the solar spots, faculæ, luminous stata, and other phenomena under a hot glare, every invention to prevent injury while scrutinising the sun is both useful and valuable. Urged by necessity, the Rev. Mr. Dawes planned an eye-piece which, under his direction, was constructed by Mr. Dolland. Its peculiarity consists in having a metallic slide, with perforations of different sizes, which crosses the eye-tube at right angles, just at the focus of the object-glass; and though the slide is greatly heated while viewing the sun, the conduction is cut off by interposing a plate of ivory. The pe[illegible] vary in diameter from 0·5 to 0·0075 of an [illegible]. Moreover, as observed in the "Speculum Hartwellianum" (p. 28), this admirable eye-piece possesses the advantage of being applicable to any existing telescope. The indefatigable inventor has now constantly used it during a period of upwards of ten years, with success, and most interesting results, as to a stratum on the solar disc, and the rotation of a remarkable spot through an arc of 100 deg. in six days! Solar investigations are, therefore, more within our reach than formerly, especially as photography and practical philosophy have brought their powerful aid to bear on the investigation.

Prof. Phillips, after acknowledging the value of the ingenious invention of Mr. Dawes, described the method by which the eminent optician Cooke had succeeded in separating the heat of the solar rays from the luminous portion before their arrival at the focus. The eye-piece constructed by him was a prism of 45 deg. and a right angle, with one of its faces presented to receive the light after leaving the object-glass; the luminous rays are then received on the back of the prism at a larger angle than that of total reflection, so that fully 95 per cent. of them are thus got rid of. By this simple contrivance the utmost comfort is secured to the observer engaged in examining the sun.

Mechanical Section.

DISCUSSION ON THE REPORT OF THE COMMITTEE ON GUN-COTTON.

Sir Wm. G. Armstrong said it was impossible to listen to the report which had been read without being very much impressed with the great promise there was of gun-cotton becoming a substitute for gunpowder; but at the same time there were certain peculiar anomalies about it which he certainly should like to have cleared up, and until they were, they could not feel that perfect confidence in the results that they wished to do. In the first place, with regard to the heat evolved, they were told that, with such a quantity of gun-cotton as would produce a given quantity of gas, a certain initial velocity was imparted to the projectile, and that the heating effect upon the gun was much less than when a similar velocity was produced by an equivalent quantity of gunpowder. The absence of heat in the gun implied an absence of heat in the gas. Where was the projectile force to come from, if there was no heat in the gas? He could not, for his part, conceive how it was possible of explanation. The next point that occurred to him was with regard to the recoil. It was stated that the recoil was very much less. That was ascribed to the absence of solid inert matter in the charge, which, in gun-cotton was next to nothing. If the recoil was only two-thirds that of gunpowder, it would require, in order to account for that difference, a much larger quantity of solid matter than there really was in the case of gunpowder. The report stated that the use of gun-cotton enabled them to reduce the length of the gun. It was quite certain, however, that with a short gun they could not get an equal initial velocity as with a long gun. If the initial velocity were increased there was more danger of bursting the gun than with gunpowder. Because if they got any velocity, or an equal velocity with the shorter gun, it must be concluded that it was done by virtue of a greater initial pressure and an earlier action upon the shot. That necessarily implied a greater strain upon the gun at the first explosion, and that would necessitate the employment of stronger guns. He should have expected a smaller velocity by a shorter gun, for the action of the gas was necessarily shorter than in a longer gun. The heat question, however, was to him the greatest puzzle of all. How they could have the propelling power without heat in the gas, and if they heated the gas, how they escaped heating the gun, he could not understand.

Professor Pole said he was quite unable to give any explanation of the difference of recoil. If the shot left the gun with the same velocity as when fired with gunpowder, it was natural to suppose that there must be the same quantity of recoil.

Mr. Siemens having briefly spoken on the dynamical question involved in the matter, suggested that the greater heat imparted to the gun in the case of gunpowder might be owing to the greater amount of solid matter, which taking up the great heat of the gases under a pressure of some 400 atmospheres imparted a portion of the same by radiation to the side of the gun; while in the case of gun-cotton gases only were produced, which could only impart heat to the gun by the slower process of conduction, and left a larger margin of heat to be developed in force by expansion.

Admiral Sir E. Belcher thought that the reason the gun was not heated by an explosion of gun-cotton might be because the gases had not time to heat the gun owing to the rapidity of the explosion, which was slower in the case of gunpowder; or that it might arise from the greater amount of fouling in the case of gunpowder.

Capt. Maury said this report was something more than interesting, because it was so exceedingly suggestive; and it appeared to him that it afforded them an element of security by giving the preponderance on the side of defence. Ever since steam had been applied to purposes of naval warfare, it had been considered a matter of very great doubt by many professional men how far ordinary steamers and men-of-war, where forts were to be passed at the mouth of a river, were capable of sustaining the fire of such forts and passing up the river. And to show that there was ample time for them to do so, they had only to recollect the fact of steamers having fought forts for several hours. In the Crimea and at Charleston the steamers had remained under fire for several hours—a much longer time than was necessary to enable them to pass the forts and go higher up the river into a place of safety where they could do damage to the enemy. Iron-clads had rendered this much more easy than it had previously been. If then their principal defences failed them at the mouth of a river in this way, the question was whether they should not have recourse to mining for the destruction of the invading vessels? He himself had been engaged upon the subject. He found this difficulty in employing gunpowder, that in order to be sure of destroying the vessel as she passed in a given line by means of gunpowder, the magazines must be in actual contact, or very nearly in actual contact with the side of the vessel; otherwise the probability was that the vessel would not be destroyed. Last week they had the intelligence of a vessel having had a mine exploded under her on the James River. That magazine contained several thousands of pounds of powder. The vessel did not know that the mine was there; but the mine did not destroy the vessel. It merely threw up a column of water, which washed some of the men overboard. His own conclusion was that to make sure of destroying a vessel after she had passed the forts, they must mine the channel in such a manner that the vessel must come in contact with one or other of the mines. It was found that wooden vessels to contain the powder would not do. They would not confine the powder long enough to produce a sufficient force. It was necessary to make them of stout boiler-iron. It would not do to leave the magazines on the top of the water, and it would not do to put them at the bottom, for then there would be a cushion of water between the bottom of the ship to be destroyed and the magazine, which would protect the vessel. In short, they had to anchor them beneath the surface with short buoy-ropes, at a depth proportioned to the kind of vessel expected to come up. But when they made the magazine of boiler-iron they had to have buoys to float it so large that they were always in danger of being carried away by the vessels crossing the line of magazine. The plan was to place those magazines in a ring in such a position that the vessel in passing would have to come in contact with at least one and probably two of them. It was necessary to place those magazines of powder so that when you saw the vessel in that range you had only to bring the two poles of the galvanic battery together and make the explosion. There was, as already stated, a difficulty in using gunpowder. But since gun-cotton had the remarkable effect of destroying a vessel—he did not know her strength—at a distance of 18 ft., and that not vertically, but laterally, the question arose whether they might not fortify and protect those channel ways by placing a ring of gun-cotton magazines along the bottom; but, at any rate, if that was not necessary, they could float them at any depth, and out of reach of the vessels generally using the channel. That appeared to him to be one of the most important uses of gun-cotton, and it was one which would give safety to cities which were some distance from the mouths of navigable rivers. He trusted that in the event of the Committee continuing their labours, they would address their attention to this important point.

Admiral Sir E. Belcher stated that the explosion of powder under water was once done under one of his own vessels to clear away ice. He placed it upon the ground, thinking that its explosion would blow the ice clear of her bows without touching the vessel. There was, however, sufficient water to form a cushion, and when the explosion took place it only produced a great wave upon which the vessel rose.

Professor Pole said what they wanted was something to show the varying pressure of the gases in the gun; in fact, an indicator diagram.

Mr. J. Scott Russell set himself to clear away the many difficulties which attended this very difficult subject. How was it that in gunpowder and in gun-cotton where there were equal quantities of gas put in, the gas in the case of gunpowder was raised to an enormously high temperature, and came out at an enormously high pressure, showing that they had gas enormously expanded by heat; whereas in the case of gun-cotton the gas came out quite cool, so that you might put your hand upon it, and the gun itself was quite cool? He (Mr. Russell) had a theory. Steam was a gas, and steam expanded just by the same laws as other gases did. A great deal of the gas of gun-cotton happened to be steam. Let them conceive 100 lb. of gun-cotton shut up in a chamber that just held it. They had got there all the gases that had been spoken of, but they had also got 25 lb. of solid water—about one-third of a cubic foot of water—in that chamber. What did they do with it? They put fuel, they put fire to it. They heated the whole remaining pounds of patent fuel. If, then, they considered the gun-cotton gun as the steam-gun, they got rid of two difficulties. They would have, first, the enormous elasticity of steam; and, secondly, they would get the coolness of it. They all knew that if they put their hand to expanded high pressure steam, it had swallowed up all the heat and came out quite cool. He believed that the gun-cotton gun was neither more or less than Perkins's old steam-gun with only this difference, that you bottled up the fuel and water, and let them fight it out with each other. They did their work and came out quite cool. He hoped, however, that it was understood that he did not dogmatise. He put all he had said with a note of interrogation upon it.

Prof. Tyndall said he thought that a note of interrogation ought to be put to what Mr. Russell had said.

Copper ore of a rich quality has been found in British Columbia. A vein of native copper has been discovered within ten miles of Victoria.

HUGHES' IMPROVEMENTS IN TELEGRAPHIC APPARATUS.

These improvements, recently patented by Mr. D. E. Hughes, electrical engineer, Old Broad-street, City, relate—1, to means for regulating or governing the motion of apparatus employed when recording telegraphic communication. Upon one of the main axes of such apparatus the patentee applies a fly or balance wheel, and opposite the end of this axis, but held somewhat inclined to it, is fitted an elastic and weighted rod capable of vibrating in a rotary direction when acted upon by an arm or connection from the main axis referred to. The vibrations thus obtained regulate and render uniform the motions of the apparatus without the necessity of an escapement. The position of the weight on the vibrating rod is capable of being regulated to the speed desired. To prevent breakage of this vibrating rod by the extent of its vibrations, a pad or friction surface is brought into operation upon a friction band or surface as the vibrations increase, in order to use up the surplus force exerted.

The improvements relate—2, to means for facilitating the ready change from one class or character of recorded sign or indication to another, as from letters to figures. For this purpose the periphery of the type wheel is arranged with the desired different signs thereon in alternate order, and this wheel is affixed to a hollow shaft or boss which receives the hollow shaft or boss of a correcting or adjusting wheel, having teeth on its periphery corresponding with those of one set of signs on the type wheel, or the intermediate positions thereof. The outer end of an arm from the axis of the type wheel passes into a recess in a lever turning upon an axis carried by the correcting or adjusting wheel, and this lever is formed at its opposite ends with projections adapted respectively to fill up spaces opposite those between teeth of the correcting or adjusting wheel. The pressing in of one end of this lever will cause the teeth of the correcting or adjusting wheel to be coincident with one set of signs on the type wheel and the pressing in of the opposite end of the lever causes the type wheel to be moved partly round on its axis, so that intermediate signs are then coincident with the teeth of the correcting or adjusting wheel. One or the other end of this lever is pressed inwards at the times desired to effect a change, when the apparatus is set in motion by the passage of a current of electricity brought into operation by acting on one or the other of particular keys corresponding with the relative position of the type and correcting or regulating wheels.

The improvements consist—3, in connecting the armature of an electro-magnet, through a small local battery, to one wire of the electro-magnet, and in connecting the other wire of the electro-magnet with a stud or projection in position to be acted upon by the armature when that is raised. By these means, upon the passage of a current of electricity into the electro-magnet, the armature is at once released, when the current of electricity, in place of continuing through the coils of the electro-magnet, flows by way of the armature and through the local battery to the main wire; at the same time, the tendency of the local battery is to restore the magnetism in the cores of the electro-magnet.

These improvements relate—4, to the means of insuring a sufficient flow of electricity for considerable lengths of wire, and when working with high speeds to the type wheel, that the duration of contact of the contact surface employed may be equal to the passage of three or more letters of the type wheel.

Fig. 1, of the accompanying drawings, represents a side view, partly in section; and fig. 2, a plan view of parts arranged according to the first part of the improvements.

a indicates parts of the framing; b, a fly or balance wheel affixed on one of the main axes of the apparatus employed in recording telegraphic communications; and, su posing these improvements applied to apparatus such as described in the specification of Letters Patent granted to Mr Hughes, bearing date the 27th of April, 1858.

HUGHES' TELEGRAPHIC APPARATUS.

FIG. 2.

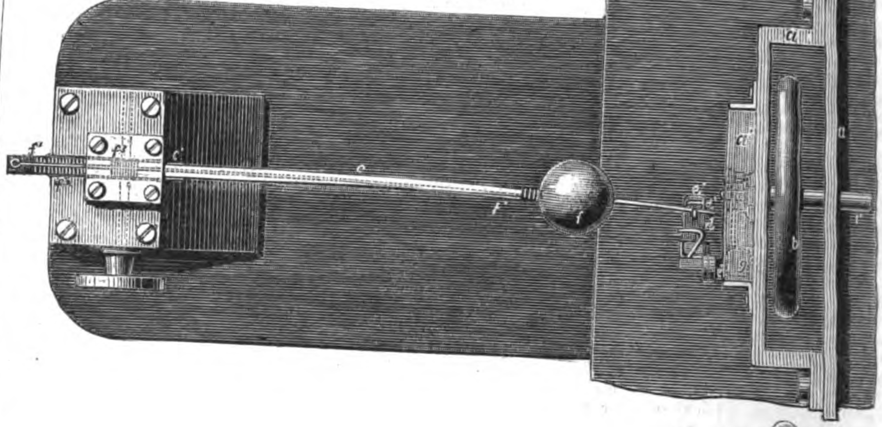


FIG. 1.

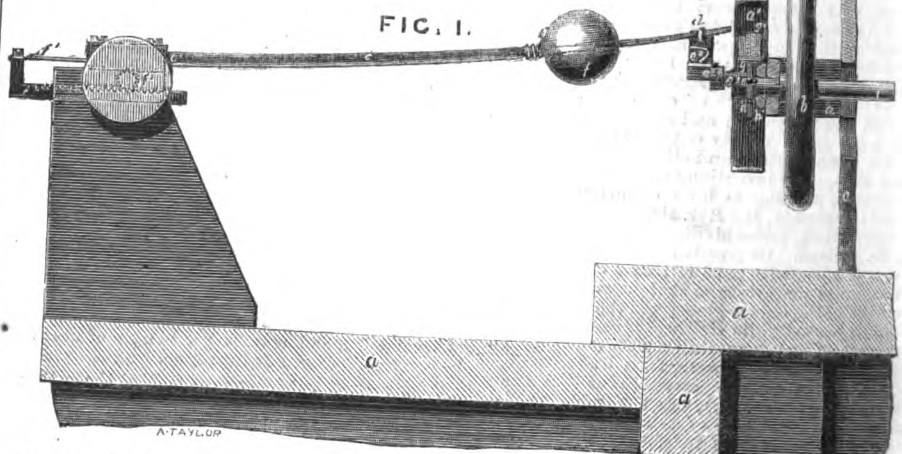

FIG. 5

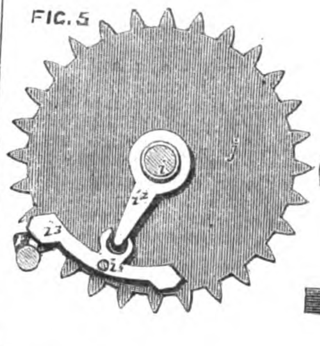

FIG. 3.

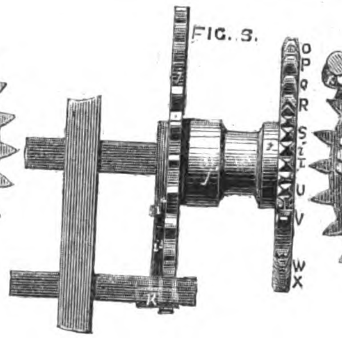

FIG. 4.

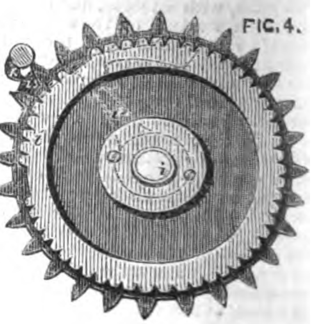
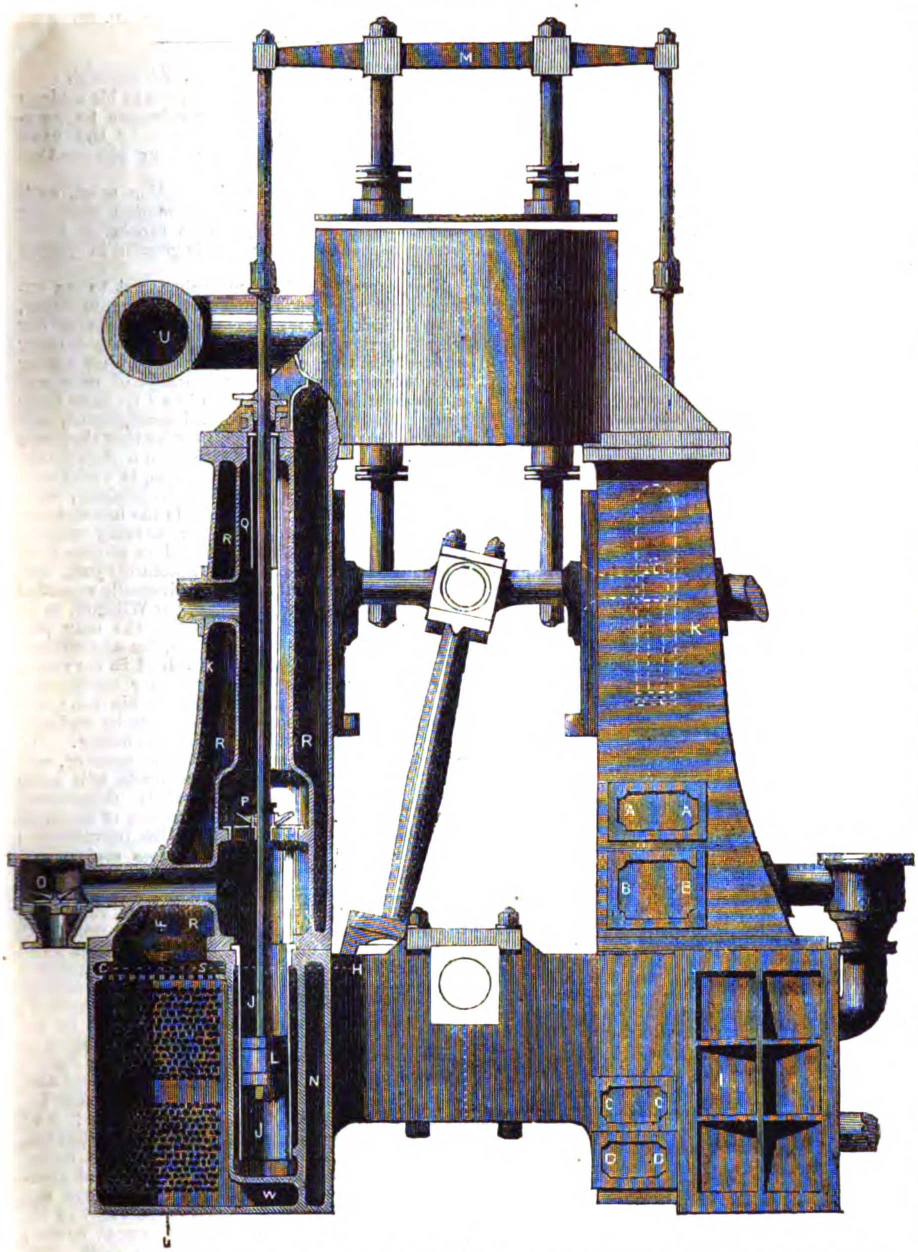


No. 938, such fly or balance wheel will represent the fly or balance wheel Z there referred to, as affixed on the axis I^1 of that apparatus, but this may be varied; c is an elastic rod, one end of which is fixed stationarily at c^1, whilst the other end passes through an eye d^1, attached to the piece of thick leather, or other suitable elastic material d, which is affixed to the boss e between the plates e^1 and e^2 affixed thereto, by which the end of the leather d carrying the eye d^1, will, when the apparatus is at rest, lie on the plate e^1, and when the apparatus is in motion the leather d will be restrained by the plate e^2. The boss e carries a pin or axis, which turns in a hole formed for it in the end of the arm affixed to the axis I^1; f is a weight capable of sliding on the elastic rod, and of being held in any desired position thereon by its being affixed to the rod f^1, to which is affixed a rack, the teeth of which are taken into by the teeth of a pinion, by which that rack is moved so as to move the weight f along the rod c. The boss e also supports the arms g and h; the arm g is furnished with a pad g^1 of cloth, leather, or other suitable material, which in the rotary vibrations of the outer end of the rod c is brought to bear against the inside of the stationary rim a^1 affixed to the framing a, and the arm g is drawn towards the flange a^1 by means of the spring h^1 acting on the arm h. By this means, as the fly or balance wheel b revolves, motion will simultaneously be given to the weight f, which, by acting on the rod c, and thence through the strap or band d upon the boss e and the friction arm g, will cause an increase of friction upon that arm, in proportion to the amount of force exerted by the tendency to increase the arc of vibration of the rod c, resulting from any increase of motive power exerted upon the apparatus, by which the effect of such power will be rendered uniform. By altering the position of the weight f along the rod c, the number of vibrations of that rod in a given time will be varied, so as to regulate and render uniform the speed of the mechanism to which it is connected in relation to another or other instruments with which it may be desired such mechanism should work in unison.

Fig. 3 shows a side view, fig. 4 a front view, fig. 5 a back view of parts arranged according to

MACE'S MARINE ENGINES.



the second head of the invention. i is the type wheel, the periphery of which is formed alternately into signs of a different character, as letters and figures, and in place of this wheel being formed on or affixed to the same boss as that to which the correcting or adjusting wheel is affixed, the type wheel is affixed to the tube or hollow axis i^1, which receives upon it the boss j^1 of the correcting or adjusting wheel j. To this hollow axis i^1 of the type wheel i is also affixed the lever or arm i^2, the outer end of which is received into a recess, as shown in the lever i^3, which is capable of moving on its axis of motion i^4, carried by the correcting or adjusting wheel j. The effect of a depression of either end of this lever i^3 towards the centre of the wheel j is to cause the type wheel i to make a slight movement on its axis in relation to the correcting or adjusting wheel j, in a direction dependent upon which end of the lever i^3 is depressed, and the amount of movement thus obtained is equal to the distance between one sign and the next, or from one character of sign to the other on the type wheel, and the depression of one or the other end of the lever is is obtained by causing the cam or tappet k to act at the time desired, in manner described in former specifications.

MACE'S IMPROVEMENTS IN MARINE ENGINES.

THE following improvements in marine engines have been patented by Mr. Charles Mace, engineer, Sunderland. In constructing inverted cylinder steam-engines suitable for driving screw propellers and other uses, according to this invention, the main bed of the engine is formed into a hollow box frame of a suitable form, and of sufficient size to receive the arrangement of horizontal tubes of a surface condenser. In this condenser the tubes are placed horizontally, but slightly inclined, and the tubes in each are disposed in a line with the keel, and consequently with the driving shaft of the engine. It is preferred that the circulation of the condensing water should be by mechanical means and through the thin metal tubes of the condenser, whilst the steam is brought in contact with the exterior surface of such tubes; but this action may be reversed. The condensers form the bed of the engine, and the hollow columns which rise above and are fixed to the condensers form the supports of the cylinders; the air-pumps are formed in the columns that support the cylinders, and are worked from cross-heads either above or below the cylinders; the pump-rods work through suitable stuffing-boxes, as shown in the accompanying drawing, which is a front elevation, partly in section, of a steam-engine, with two steam-cylinders and condensers arranged or combined according to this invention.

I, I, are the hollow boxes or bed plate of the engine containing the tubes, constituting the surface condensers; the tubes in the condensers are arranged parallel to the keel and to the main shaft of ths engine; J, J, are pumps in the columns K, and such pumps descend below the upper surfaces of the boxes I, as shown. The pump-rods ascend through stuffing-boxes, as shown; and such rods may be either worked by a cross-head M above the cylinders, or by continuing the lower cross-head in the manner shown by dotted lines in fig. 1, so as to have the pump rods fixed thereto. The lower cross-head of each steam cylinder gives motion by a connecting rod to a crank of the driving shaft of the engine. The lower cross-head of each steam cylinder is connected to two piston rods of such cylinder, and the cross-head is guided at its ends, as is shown in the drawing; the hollow boxes constituting the bed of the engine are connected by cross-beams which carry the driving shaft of the engine. L, L, are the buckets of the pumps; O, O, are suction valves; P, P, the delivery valves; Q, Q, are air-vessels formed in the upper parts of the columns; R, R, are exhaust passages formed in the columns leading from the steam cylinders to the condensers; S, S, are the exhaust passages into the condensers; T, T, are perforated plates to diffuse the steam into the condensers; U, U, are the steam pipes; V, V, are the foot valves of the air-pumps; W, W, are the passages from the vacuum spaces to the foot valves of the air-pumps; X, X, are the delivery valves to the hot well N, N; and Y, Y, are the circulating water spaces of the condensers; A, A, are the delivery valve doors; B, B, are the bucket doors; C, C, are the delivery valve doors to hot well; and D, D, are the foot valve doors. In working the pumps the down-stroke of the buckets L draw off the water from the condensers. The up-stroke of the buckets closes the suction valve O, O, and forces the water through the delivery valves P, P, and thence into the sea when the engines are used propelling a ship or vessel. In order that the condensers may be used in the event of any defect in the tubes, the patentee introduces ordinary injection apparatus, and then uses the condensers in the usual manner of ordinary injection engines.

THE STEERING SCREW-PROPELLER.

A SERIES of very interesting experiments was carried on last week at Sheerness, by order of the Admiralty, to test the value of a steering screw-propeller applied to the "Charger" gunboat, the invention of Mr. W. J. Curtis, C.E. The peculiarity of this screw is that a ring forming a universal or ball-and-socket joint, is placed within the hollow boss of the screw, which is thereby connected with the main shaft, the centre of gravity of the screw and the centre line of the rudder intersecting the centre line of the main shaft, so that the entire weight of the screw is borne by the shaft; and by means of the tail or spindle of the screw projecting from the boss working in the rudder, whatever may be the movement of the rudder, it communicates an equal movement to the screw, which therefore becomes not only the propelling but also the guiding power of the ship. Furthermore, by this invention the retarding action of the rudder and likewise the vibration are removed, while the speed of the vessel is increased. The "Charger" gunboat, having been handed over to Mr. Curtis for the purpose of making experiments, was on Wednesday taken for trial at the measured mile off Maplin Sands, the result being that the mean of the runs to and fro was 8·698 knots an hour, as contrasted with 7·751 knots obtained at Portsmouth previous, showing a gain of ·531, or about half a mile, in favour of the steering screw, while the indicated horse-power showed 113·30, against 145·25 obtained at Portsmouth. It was felt by those who witnessed the experiments that, had the engines been in a more efficient working state, the gain would have been still more considerable. On Thursday a competitive trial of speed took place between the "Charger" and the "Spanker," twin boats, having been built upon the same model and

lines by the same builders, and each containing engines of 60-horse power. The distance run was from a buoy off the "Formidable," flagship, at Sheerness, round the Nore Light and back, a total distance of about eight miles. In this distance the "Charger" beat the "Spanker" by 17 minutes, being 25 per cent. gain, or equivalent to about a mile and a half per hour, the whole run being made by the "Charger" in one hour and one minute. This gain is evidently obtained by avoiding the retarding effect of the rudder, as it was found that, to keep the vessel in her course, the helm never varied more than from 3 to 5 deg. The full circle was made in 2 minutes 40 seconds, helm starboard 50 deg., the diameter of the circle being 120 ft., measured by a line paid out from the stern of the ship. The circle to port, helm 40 deg., was made in 2 minutes 30 seconds, diameter the same, the length of the vessel being 115 ft. By working the screw astern and putting the helm over 40 deg. the vessel can be turned in about half the time above stated and in a radius of only one-third its length, measuring from the screw itself. The screw can be applied in the dead wood of the ship, and lifted as in the ordinary way, so that the vessel may be governed either by the rudder or screw, or by both, at the option of the commander; also, if found necessary or desirable, the rudder may control the movement of the vessel by the momentum after the engines are stopped; but all that has been sought or could be expected by a first trial is the establishment of the principle of the invention, which is considered to be proved beyond all question. Its value to large ships must be apparent, whether for war or commercial purposes.

A FRENCH IRON-CLAD.

THE "Magenta," one of the most celebrated vessels in the French navy, is described as a line-of-battle ship—that is to say, she has nothing in common with those strange-looking machines, those "Monitors," &c., invented by the Americans. When seen from a distance in the midst of a squadron, she might in some measure be taken for an ordinary vessel, only lower in the water, but a nearer approach discloses some unknown features. Higher out of the water forward than aft, she presents the appearance of an enormous black mass, insensible to the action of the waves on which the other vessels near her gracefully move, no streaks indicating her rows of teeth, scarely any masts, very sharp both at stem and stern, terminating at each end like a wedge, and having at her bows an immense spur or ploughshare—those are the differences shown at the first glance, but when you go on her deck they become still more apparent. Her masts are those of a steam corvette, with only the rigging indispensably necessary to keep them standing. In combat everything is reduced to the lower masts. The boats, instead of being suspended to davits outside, are on deck, which is flush from stem to stern, and no guns are to be seen, with the exception of two bow-chasers. Nearly amidships, by the side of the funnel, is an iron-clad shot-proof kind of turret, which contains the means of communication with all the other parts of the vessel for the transmission of orders for working her, and for the fire of her guns. In action every one goes below, and this turret alone is occupied by the captain, another officer, some signal men, and a few sharpshooters. It is from this turret that all the orders are given. From the upper deck you descend into the gun decks, two in number, each having 24 rifled and breech-loading guns. Those pieces throw 60 lb. shot with an ordinary charge of 6 lb. of powder. All the armed part of the vessel, down to below the water-line, is iron-clad, but the casing does not extend quite to the stem or to the stern, as in the "Gloire" and "Normandie" frigates, the object of the change being to lighten the vessel. The parts not iron-clad are used—those aft for the cabins of the officers, and those forward for the quarters of the crew, the cooking, and the hospital—an innovation of material importance as regards the health of the sailors. In the iron-clad vessels first built everything was sacrificed to solidity, and the openings left for giving air and light were so few that those vessels were regular ovens. Every one remembers what the crew of the "Normandie" suffered when so placed under the burning sun of Mexico. The engine of the "Magenta" is similar to that of the "Napoleon," and is of about 2,700-horse power. Under full steam, she can make from 13 to 14 knots an hour. Her screw has six blades. The consumption of coal is 130 tons a day, and she can stow away from 700 to 800 tons. Moreover, her spur weighs 15 tons.

TO CORRESPONDENTS.

LUCIAN TWEED.—It means simply that he lodged his specification, which, of course, appeared in the list of Provisional Specifications. All the specifications are published, whether protection is or is not granted about six months after they are lodged. 2. Because it is not novel, or has been published or patented before, or is not likely to be of benefit, or because it is not patented by the real inventor or his legal assignee.

A.S. (Manchester).—We believe it is patented all over the Continent and in America.

RECEIVED.—H. R. E., S. T., C. C., J. H., J. C.

STEAM BOILER EXPLOSIONS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I have read your report of the Astronomer Royal's Paper, read at the British Association, on Boiler Explosions, and, had it not been from inability, I should have been present, which would have saved any remarks from me here, as I should have given this explanation before the section. I have also been surprised at the articles on this subject in your contemporary, the *Engineer*. The explosive properties of water, when under a high temperature, are well known to most practical engineers; and if your pages were examined, it will be found that this subject has been explained so far back as 1827, and in other scientific publications, which have been published from time to time, if I remember right, by Mr. Gilman and others. The celebrated Mr. Parkins, the engineer, constructed a steam-engine to be worked by highly-heated water, when set free, and allowed to explode into a copper vessel, and then to the cylinder and piston through pipes connected with the collecting chamber. In 1851, Mr. W. Fairbairn delivered two lectures at Leeds on boiler explosions, which I attended. Mr. Fairbairn fully explained the explosive property of highly-heated water, and illustrated it by an experiment in the lecture-room. I have more than once explained the principle, before coroners' inquests and juries, when examined by them as to the cause of the boiler explosion they were inquiring into. One of my reports, of which I have now a copy before me, will explain all that need be said upon the subject.

REPORT.

"The shell or outer diameter of the boiler was torn and crumpled as though it had been paper: this, to many people, appears marvellous, who express their surprise that the steam contained on the upper side of a boiler, in what is termed the chamber and steam-room, should have such immense force; but it is not so much by the force of the steam proper as the highly explosive property of the water, when heated to a high degree of temperature and then instantly relieved from that temperature and pressure by the boiler giving way; hence follows the awful destruction, by the water exploding, as though it was ignited gunpowder."

I have known when the manhole lid has been removed suddenly from a boiler in which there has been steam pressure, and has emptied the boiler of water through the manhole. Not very long since, at Hull, the weight from a safety-valve lever was suddenly removed and the pressure released; the consequence was an explosion of the water. It has long been understood by even the fireman that the damage done by the explosion of a steam boiler was principally occasioned by the explosion of the water. Those who have noticed the steam let out of a boiler have also noticed it lowering the water from 2 in. to 6in. according to the pressure, thus proving the large quantity of water ready to escape in the form of steam when the resistance has been removed. I confess it has been amusing to read your contemporary on this subject, as though he had discovered something—placing himself the first, and the Astronomer Royal the second.

I remain, sir, yours respectfully,

J. HOPKINSON

Britannia Works, Huddersfield,
September 15, 1863.

[We have inserted Mr. Hopkinson's letter, though we are at a loss to understand its object. The simple assertion that hot water is explosive without stating why it is so, is worthless. If Mr. Hopkinson understands the solution of the problem, the fact of his suppressing it is anything but commendable, as by publishing it he would have conferred an important boon on the scientific world.—ED. M. M.]

SIR W. ARMSTRONG *v.* PATENTS.

SIR,—Sir W. Armstrong's remarks in his address to the British Association, with reference to inventors and patents, are characterized by the usual plausible superficiality displayed by him on that subject.

He said that the seeds of invention exist, as it were, in the earth, ready to germinate whenever suitable conditions arise, and no legislative interference is needed to ensure their growth in proper season.

Now, carrying out his metaphor, not to an extreme, but only to a fair and most legitimate extent, I would ask Sir William—Did the seeds of our wheat, barley, oats, turnips, and potatoes occur *naturally* in the earth; and did, or do, they spring up *spontaneously* to satisfy the wants of man, and of the animals dependent upon him? Or have these seeds been the subject of careful development, and always of careful cultivation, in order that they may produce what is wanted? And when a man grows a field of wheat, or of any thing else, is everybody to be allowed to help himself to the produce, without money and without price? Is the interference of Government in order to ensure to every man the fruits of his lawful labour—mental or physical—in place of being most expedient, absolutely just, and perfectly necessary, as hitherto universally regarded —to be viewed, at the bidding of Sir William, as an entire mistake? Most assuredly the man who would argue, as Sir William does, for the absurd results as are thus seen to be involved in his views, may be a very clever, or a very lucky mechanist; but that "a screw" must be loose in his own intellectual and moral mechanism, seems to be perfectly clear, and the sooner it is rectified the better. The patent laws are most creditable to our country, and most beneficial; and they will be made still more so by being improved; while their destruction would be an act of thorough barbarism, of the most disgraceful injustice, and of the vilest ingratitude; for what, it may be well asked, does society not owe to its discoverers and inventors? They pioneer the way, fight in the van, and are the great advancers of civilization. The patent laws, therefore, so far from being abolished, ought to be made still more effective by due modification, by proper scrutiny, and by their quick and cheap administration; while the ideas of Sir W. Armstrong on the subject —involving, as they do, ingratitude and robbery of, I hesitate not to say, the deepest dye—must be regarded as symptoms of as strange a hallucination as ever afflicted the human mind, leading as it does a man in the position of Sir William to become the open, the unabashed advocate of the grossest injustice, and of the most shameful illiberality! And I beg leave, therefore, to tell Sir William that the sooner he recants his present opinions, the better will it be for his own reputation, morally and intellectually. It will be observed that I have not alluded to any motive of a merely selfish sort as influencing Sir William to adopt his present course, believing that his conduct arises from most erroneous ideas of what would be best for the public interest. But he may always rest assured that the public interest will ever be best promoted, in the long run, by doing justice to all, and especially to those who discover and invent what is beneficial to mankind. He may rest assured that nothing great could be expected of a nation who could be guilty of injustice and ingratitude to its benefactors—as it would indicate a low, and degraded tone of moral and intellectual feeling, from which I trust, and have no hesitation in saying, the British public will ever be exempt; for a blacker day for Britain could not be conceived than when it should be otherwise.

Edinburgh, Sept. 13, 1863.

H. K.

Miscellanea.

During the recent meeting at Newcastle, opportunity was taken of an excursion of the British Association to the Marsden rocks by steamer, to exhibit the properties of Clifford's boat-lowering apparatus. The experiments were perfectly successful.

The *Phare de la Loire* states that two steamers are being constructed at Nantes, the object and destination of which are surrounded with mystery. The vessels are 80 metres long, are to have two engines of 400-horse power, will carry 22 guns, and their guaranteed speed is to be 14 knots an hour.

Speed would appear to be one of the main objects aimed at in their construction, as they are remarkably narrow, and their stems are said to be as sharp as the blade of a razor. A very suspicious circumstance in connection with them is that they are to be delivered up at sea, 20 leagues from Belle-Isle. It is generally believed, the *Phare de la Loire* says, that these vessels are intended for the Confederates.

We have received a pamphlet, just published, entitled, "A Southern Clergyman's Exposition of the Oath of Allegiance." We beg to inform the author and publisher of the pamphlet that the MECHANICS' MAGAZINE is a scientific and not a political journal. We have, like most men, our opinions and sympathies on the American revolution—the greatest revolution that ever shook a nation or a continent. We have, however, little or no sympathy with a class of men who are endeavouring to build up an iniquitous empire on the ruins of freedom, and still less sympathy with clergymen who blasphemously appeal to the sacred sanctions of Christianity in behalf of such a godless work.

The "Kirkham," 1,061 tons registry, with about 187 miles of the Indian telegraph cable on board, left Gravesend, on Friday, for the Persian Gulf, her precise destination being Bagdad. This is the second portion that has gone out, and the remaining lengths will be conveyed in three sailing vessels and a steamer. The entire length is upwards of 1,200 miles, and the weight about 5,000 tons.

A new blue has been produced, less costly than indigo, which may affect a large class of interests in India.

While we, as a Government, are about to make an experiment with the application of the double screw to a steam tug of 35 tons, the Federals in North America have, we are informed, resolved upon constructing four ships of 330 ft. in length, to which they intend to fix twin screws. We know that Lord Lyons and Sir Alexander Milne never lose an opportunity of forwarding useful information to the Foreign Office and to the Admiralty; but we should be more pleased if we were certain that their labour was not wasted. We are still dependent upon our old 95 cwt. or 8 in. gun, while the Americans are provided with—as we have often previously stated—15 in. guns of 20 tons weight, and capable of throwing shot of from 420 to 450 lb.; and while they will shortly be able to turn their longest ships almost upon their own axis, we still require a space nearly as large as Spithead, in which "to wind" our "Warriors," "Black Princes," &c.

The 24th company of Royal Engineers, at Aldershot, have lately been carrying on a series of siege works on the banks of the Basingstoke Canal. A number of models on a scale of one-sixth of elevated, sunken, and half-sunken batteries were constructed, and also trenches and communications. A number of model magazines were also made. A course of lectures on the subject of siege works, &c., delivered by Capt. W. A. Frankland and Mr. Hill, R.E., was well attended by the company. These operations are understood to be preparatory to the erection of siege works on a full scale, which it is intended to erect on the vacant ground between the North and South Camps. These latter works will be carried on very rapidly, orders having been issued for the men to work night and day, as in actual warfare. Large quantities of gabions, fascines, &c., have been made by the Engineers, and now stand ready for use.

We learn from the *Army and Navy Gazette*, that the Newhaven experiments were brought to a close on Friday evening last, after successive discharges from the 110-pounder, 70-pounder, and 40-pounder breech-loading Armstrongs. We regret to say that, under somewhat quicker firing of the last day, the defects of lead-coated shot and fine grooving were made only too apparent, the whole of the rifling of these guns leading on their becoming warm, and impairing the accuracy. As happened in the previous practice with the full charge of 12 lb., several of the shells burst at the muzzle, and one in the gun itself, cutting up the grooving, while others of the shells were stripped of their lead coating, and fell short. Last Thursday's experiment, which was conducted partly to try the fuzes, showed that the 110-pounder could not be depended upon in the hour of greatest need in a close hand-to-hand combat, and established also the fact that the peculiar nature of the Armstrong rifling rendered it very difficult, if not impossible, to obtain a safe fuze for the gun. Colonel Boxer's time-fuzes, with the "Moorsom" hammer, were not tried, owing to his not having perfected some of the minor details.

Though commanding a squadron composed of some of the most powerful ships in the Navy, Admiral Dacres, at a banquet given by the Glasgow Corporation, has expressed an opinion highly favourable to the use of war vessels of a much smaller class. He illustrates his remarks by a reference to the "Alabama," and stated that it was to such vessels as her that we must look for a clearance of the seas in actual warfare.

The *Siecle* publishes a despatch from Brest, stating that the "Florida" has been provisionally seized at that port, at the suit of a shipowner named Menier, of Brest, who claims an indemnity of £100,000f. for one of his vessels, seized by that cruiser.

A large massive cylinder, 6 ft. 5 in. bore, 16 ft. stroke, and weighing 40 tons, was cast at the Elswick Engine Works Foundry, on Wednesday week. The running of the metal occupied five minutes. It is for a steam hammer for the Russian Government. Several ladies and gentlemen were present during the operation. Captain Noble, Mr. H. M. Brunel and friends, and Mr. George Cruddas were amongst the spectators.

Last week a new locomotive for mineral traffic, constructed by Messrs. Dick, Stevenson, and Dick, for Robert Baird, Esq., Limerigg Colliery, passed along the street from their works to the Hallcraig Station of the Monkland Railways, propelled by its own machinery and attended by an admiring crowd. The only occasions where steam required the help of manual labour was in making sharp turns. A few turns taken along the rails put the efficiency of the machinery to a test which it bore satisfactorily.

The patent tanked ship "Jane," Captain Dawson, arrived in the Mersey on Saturday from Philadelphia, with a cargo of crude petroleum oil in bulk, belonging to the Liverpool and Romsey Oil Refining and Chemical Works Company (Limited). This is the first iron tanked vessel with petroleum that has arrived in Liverpool. The "Jane" was specially constructed for carrying oil from America to the company's works at Romsey, where it is discharged into hermetically sealed floating tanks, which are moored in the river, thus preventing the smell and waste from leakage so much complained of in Liverpool. The vessel, made the passage in twenty days.

On Monday one of the steam rams, concerning which so much has recently been said, was towed out of Messrs. Laird's dock at Birkenhead, and taken into the Morpeth Dock Basin, where it is understood the remainder of her fittings will be completed. It is expected that her trial trip will take place in a few days. It is but right, however, in the meantime, to state that her builders do not affect any mystery or secrecy with regard to what is going on in their works. On the contrary, they have invited Admiral Dacres and the officers of the Channel fleet to visit their building-yard, and inspect all that is going on there—a privilege which has been availed of to a considerable extent. A similar privilege as to inspection has also been conferred on the officers of the fleet by the Mersey Steel and Iron Works.

A course of experiments is now in progress in the Royal Arsenal at Woolwich which promises important results. A 32-pounder cast-iron service gun, strengthened on Capt. Palliser's plan, has been tested by firing a double-proof service charge, of 36 lb. of powder, and a cylinder gradually increased in size. The gun was fired upwards of 100 rounds without manifesting the slightest signs of giving way, and burst at the 107th round. The result is considered exceedingly favourable, and has been reported accordingly to the War Department. A number of cast-iron service guns have been consequently placed at Captain Palliser's disposal, to be bored and altered in accordance with his principle, and to be similarly tested at the Arsenal proof butt at Woolwich. Captain Palliser, it appears, has for many years, applied himself, to the study of cast-iron ordnance. His plan consists in removing a portion of the existing metal from the interior of the gun and inserting a combination of steel and irom tubes in such a manner as to relieve the outer cast-iron case from all strain, whereby the gun acquires all the advantages of the present wrought-iron ordnance. Capt. Palliser, it is understood, maintains the principle that steel and wrought-iron tubes of limited thickness can be so inserted into cast-iron skins or outer portions of the existing service guns as to relieve the structure from all strain, and that only a small portion of the gun is required to resist explosion, the remaining portion being useful merely to prevent recoil. Several guns are being prepared on Capt. Palliser's plan, and, should the issue of further experiments be such as to establish more fully the correctness of his theory, the cast-iron guns now in store in vast numbers may be utilised with economy and advantage.

We learn that a target-shield, for the embrasures of casemated batteries, is about to be constructed to test a plan submitted to the War Department by Mr. Chalmers, the inventor of the ship-armour target, which proved so successful last April. Mr. Chalmers was indebted to the generosity of Sir Morton Peto for his first target; but this, we believe, is ordered by Government.

We have authority for stating that the capital necessary for carrying out the Atlantic Telegraph enterprise in the best manner has now been provided. Tenders and specimens from eight contractors have been received in reply to the company's advertisement. These were all submitted to the scientific committee appointed by the directors, and consisting of Captain Galton, R.E., Professor Wheatstone, Professor Thomson, Mr. W. Fairbairn, and Mr. Joseph Whitworth. This committee have sent in their report, unanimously recommending the Board to accept the tender of Messrs. Glass, Elliot, and Co. The directors have accordingly accepted Messrs. Glass's tender, and entered into a contract with that firm, whereby the latter are bound to manufacture a cable of the best description, to be approved by the scientific committee and the Board. They also undertake to lay the cable across the Atlantic in 1864. The manufacture of the cable has already commenced.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 357, 372, 389.*
BOILERS AND FURNACES, 358.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 373, 378, 382, 396, 416.
SHIPS AND BOATS, including their fittings, 377, 401, 407.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 359, 381.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 419.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 354, 361, 366, 367, 371, 375, 380, 390, 392, 393, 398, 408, 410, 415.
BUILDINGS AND BUILDING MATERIALS, 363, 370, 374, 384, 413.
LIGHTING, HEATING, AND VENTILATING, 364, 368, 395, 399, 414.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 360, 379, 383, 386, 387, 394, 400, 403, 405, 409, 417, 418.
METALS, including apparatus for their manufacture, 353, 355, 365, 369, 385, 388.
CHEMISTRY AND PHOTOGRAPHY, 376.
ELECTRICAL APPARATUS—*none*.
WARFARE, 362, 406, 411.
LETTER-PRESS PRINTING—*none*.
MISCELLANEOUS, 352, 356, 391, 397, 402, 404, 412.

352. G. REDRUP. *Improvements in machinery for the cutting of shives, bungs, corks, spiles, and vent or other pegs, and also in machinery for manufacturing the knives or cutters employed therein, such machinery being also applicable to the manufacture of trenails and other cylindrical and conical articles.* Dated February 7, 1863.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

353. D. GROUCUTT. *An improvement or improvements in the manufacture of iron for making nails.* Dated February 7, 1863.

This invention consists in so manufacturing strip iron for the manufacture of nails as to avoid the waste caused by trimming, and to make the iron fibrous in the direction required for making nails. This the inventor effects in the following manner:—He takes a pile or faggot of good iron, and passes it through bolting or breaking down rolls, and immediately as it issues from these rolls he passes it without reheating through heavy suitably grooved rolls, driven at a high velocity, by which it is drawn out to a considerable length, perfectly parallel, very tough, and of much greater width than has hitherto been produced. In this state it is ready to be cut up into nails, and the fibre will be in the suitable direction for such purpose. *Patent abandoned.*

354. B. Dobson and E. Barlow. *Certain improvements in carding engines.* (A communication.) Dated February 9, 1863.

This invention consists in certain improvements upon the carding engines for which letters patent were granted to George Wellman on the 11th day of September, 1860, No. 2190. In the specification of the patent above referred to, the machinery described acts successively upon each alternate top card or flat to clean it, thus cleaning all the top cards or flats an equal number of times. Now the present invention consists in so modifying the machinery that the flats near the "licker-in," or the working and clearing rollers, when such are employed, are cleaned oftener than those near the doffer.

355. H. G. Williams and R. Price. *An improved machine for crushing and amalgamating auriferous quartz, and pulverizing and washing ores.* Dated February 9, 1863.

For the purpose of crushing the quartz, the inventors use an iron cylinder or barrel, mounted horizontally in bearings at each end, and inside this cylinder or barrel is or are placed one or more balls; the cylinder or barrel is then caused to revolve by suitable gearing. The inner surface of this cylinder or barrel is corrugated, or has alternate ridges cast on it, so that, upon its being set in motion, the ball or balls is or are carried a little distance round with the cylinder, until the centre of gravity of the ball or balls falls outside the projecting rib or ridge, when it of course immediately rolls over the temporary obstruction, and adds the effect of a blow to the simple weight of the ball, which greatly increases its crushing or pulverizing power upon whatever material may be placed in the cylinder to be acted upon. There is also mercury introduced into the cylinder with the quartz, by which the metal contained in the quartz is amalgamated with the mercury, at the same time that the crushing is taking place. *Patent abandoned.*

356. J. Macintosh. *Improvements in obtaining and applying motive power.* Dated February 9, 1863.

This invention consists in the rapid generation of power by the aid of oxygenous fuel, composed either of collodion, coke, coal, wood, nitrate of soda, or coke and nitrate of potash; in some cases sulphur may be used, or the chloride of potash, and, if desired, put into form with adhesive substances, such as mineral or vegetable pitch, resins, paraffin, gutta percha, caoutchouc, or glue. The prepared fuel is put into closed tubes or furnaces with valves for the escape of the gaseous products of the combustion, which may be used alone or in combination with steam, air, or other fluids in giving motion to the machinery. This oxygenous fuel may be put into ordinary steam boilers, which fuel, when ignited, instantly produces power to give motion to engines; or it may be used for other purposes where immediate power is required, or as an auxiliary. *Patent abandoned.*

357. D. Law and J. Downie. *Improvements in traction engines or common road locomotives.* Dated February 9, 1863.

This invention is not described apart from the drawings. *Patent completed.*

358. J. Goucher. *Improvements in regulating the admission of air into the furnaces of steam boilers.* Dated February 9, 1863.

This invention consists in regulating the admission of air into the furnaces of steam boilers by means of a spring or weighted piston, acted upon directly by steam from the boiler, and connected by a rod with a valve or damper in the furnace door. According to the pressure of steam in the boiler, so will the valve or damper be more or less closed. *Patent completed.*

359. H. and J. Smith. *Improvements in drills or machines for depositing seed and manure.* Dated February 9, 1863.

This invention has for its object to arrange and construct the several parts of the machine in such a manner that the tins or funnels for conveying the seed or manure down to the coulters may hang straight down, and be less liable to become damaged or put out of order than heretofore. *Patent abandoned.*

360. W. B. Rooff. *An improved respirator.* Dated February 9, 1863.

This invention consists of a respirator, partly an improvement upon that patented by the present inventor, dated the 21st day of September, 1848, No. 12,273. The inlet tubes or passages are made to communicate with a chamber or receptacle, into which can be placed at pleasure air-purifying materials, or a piece of sponge, or other suitable material for holding medicinal preparations which impregnate the atmosphere before entering the lungs. A system of valves is used similar in action to those described in the patent dated as above, by which the exhaled air is not allowed to pass through the chamber containing the medicinal or purifying agents, but gives up its heat to the metal tubes, which heat warms the inspired air before it reaches the purifying or impregnating chamber on its way to the lungs. *Patent abandoned.*

361. J. Crosby and J. B. Smith. *Improvements in carding engines for carding and drawing flax tow, in part applicable to carding cotton and other fibrous substances.* Dated February 10, 1863.

This invention is not described apart from the drawings. *Patent completed.*

362. T. Hill. *Improvements in the arrangements employed for the protection of markers at rifle butts.* Dated February 10, 1863.

This invention has for its object the better protection of the markers when engaged at rifle butts or targets, in combination with the means employed of indicating the score, and position of the shot-mark upon the target, whilst the marker is in the act of wiping out the same, for which latter purpose letters patent were granted to the present patentee, dated July 12, 1862 (No. 2007), in connection with pits of improved construction sunk in front of the target for the protection of the marker. The present improvements are applicable to rifle-butts or targets where mantlets or shields are employed for the protection of the markers, the mantlet or shield being placed close to the target, and so arranged and constructed that the marker can readily see where the target is struck, and then by means of the brush and signal combined wipe out the shot-mark, and at the same time indicate its position to those at a distance without exposing himself to danger. For this purpose a mantlet is erected on one side of the target of any suitable shot-proof materials, the side or edge nearest the target being formed with a wing or wings placed at an angle inwards towards the marker, and having a small window protected with strong plate glass, and, if necessary, covered with wire gauze or other suitable material, through which the marker can readily see the face of the target. Near to the edge of the target a splash-board is placed, and between the wing of the mantlet and this board a narrow space is left so that the marker whilst looking through the window or opening for the sight can pass the combined brush and signal through the space, and thus readily wipe out the shot-mark, and at the same time indicate its position upon the target in the manner described in the specification of the former patent before referred to, but in which arrangement the marker is protected by a pit that is sunk in front of the target. *Patent completed.*

363. R. Burley. *Improvements in handles for hammers, mallets, picks, mattocks, and similar tools.* Dated February 10, 1863.

This invention consists, according to one modification, in making the handle of two or more longitudinal pieces of wood, of the same or of different kinds, glued or otherwise cemented together. *Patent completed.*

364. M. Wigzell. *Improvements in machinery or apparatus and method to be used in the manufacture of every description of candles, tapers, and other lights.* Dated February 10, 1863.

By the machinery or apparatus employed by the patentee he makes the candles, tapers, or other similar lights complete, that is to say, so that they will pass out of the machine with wick points, and of any required length, diameter, or shape, and at any speed that the machinery grease or other material or materials can be worked; and he places the wicks in the candles whilst the candles are being made, as well as by the other methods herein stated; and by the said machinery he makes the candles and other lights principally by pressure, that is to say, he forces the grease or other material when either cold, hot, or in a semi-cold or hot state, through tubes or apertures, so as to form them into any required shape or size, with or without wicks, and when they are thus formed, he cuts them into any required length, and points them by a pointing apparatus that is attached to the machine. Or he shapes the ends by forcing the grease into moveable pointing dies attached to the machine; or he points the candles in a separate revolving, cutting, or pointing apparatus after they have been made with the wicks in them. *Patent completed.*

365. M. Cartwright. *Improvements in combining plastic substances with metals.* Dated February 10, 1863.

This invention consists in combining by grinding together a solution of vulcanized india rubber, or plain india rubber or gutta percha, and metal leaf or metal in a state of finely divided powder. Instead of a solution of india rubber or gutta percha, the patentee sometimes uses kampticon, parkesine, dissolved amber, gum copal, or other suitable vehicle, or two or more of these substances combined. After grinding the materials together, he sometimes subjects them to heat for the purpose of hardening, and in some cases of "curing" them. *Patent completed.*

366. J. F. Bottom. *Improvements in means or apparatus for dressing lace and other fabrics.* Dated February 10, 1863.

This invention consists in substituting for the ordinary frame endless bands, straps, or chains with pins as the means of holding the fabric to be dresed by giving sideway tension to it. Such bands, straps, or chains are supported and guided in moving along the opposite sides of the apparatus, whilst at the ends of the apparatus they pass over suitable guide pulleys or rollers, so that having passed over the pulleys or rollers of one end, they pass underneath to the opposite end, and they may be of lengths adapted to the longest length of fabric required to be treated; and the fabric in place of moving to and fro will be constantly moving in one direction. *Patent completed.*

367. W. Whitaker. *Improvements in apparatus and processes for steeping, boiling, washing, bleaching and dyeing fibrous materials or slivers, stubbings, rovings, yarns, or woven fabrics of the same.* Dated February 10, 1863.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

368. A. Corneau. *An improved hot-air stove.* Dated February 11, 1863.

This stove is made for the purpose of burning pit coal, but it can also be fed with coke. The fire is kindled at the top, and descends as the burning progresses. From this new arrangement it results that the carburetted gases are completely burnt as they flow through the layer of burning coal which produces an evident saving of coal, because the inflammable gases are burning and producing heat whilst in other similar apparatus they are utterly lost. *Patent completed.*

369. H. Donald. *Improvements in machinery for shearing, punching, and rivetting metals.* Dated February 11, 1863.

This invention consists, according to one modification or system of arrangement, of an ordinary punching and shearing machine combined with a machine for cutting or shearing angle iron, and for punching or rivetting metal plates, the machines being so arranged that they may be worked either jointly or separately as required. On the sole plate of the ordinary punching and shearing machine is arranged the vertical framing of the machine, and the steam engine which gives motion to the moving parts. On the overhead crank shaft,—which is driven from the engine—is fitted a pinion, which gives motion to an intermediate wheel on a horizontal shaft arranged parallel to the crank shaft. On this second shaft is a pinion which drives a spur wheel, fitted on a shaft which extends across the centre of the machine, and operates the main lever of the angle iron machine. This machine is carried upon a suitable sole plate arranged at right angles to the punching and shearing machine. Extending up from the sole plate are two strong standards, which support the main lever carrying the shears; these standards extend each way in a lateral direction, and are recessed on each side to receive the lower cutters or blades of the shears. Below these recesses openings are formed in which horizontal punches traverse to and fro. The main lever has cast on it a short transverse shaft, which is carried on bearings arranged in the standards; its outer end extends over the contiguous shear cutter, and a corresponding cutter is fitted to the lever over the inner recess. These shear blades or cutters are of an angular form at the lower edges, so that they do not come down flat on the plate to be cut, but divide it from the outer edge first, and gradually advance, similar to the action of a pair of scissors. The inner end of the lever extends towards the contiguous punching machine, and is connected to a strap encircling an eccentric which moves to and fro upon a feather formed on the main driving shaft of the punching machine. The eccentric is made with a segmental opening in it, so that when moved slightly along the shaft by means of a hand lever, a crank pin fixed in the face of the contiguous spur wheel takes into the segmental opening, and communicates motion to the lever. Below the bearing portion of the lever there is a prolongation in which is fitted the pads that act on the rams of the punches, and cause them to operate alternately. *Patent completed.*

370. E. T. Hughes. *Improvements in apparatus for drilling wood, stone, iron, or other materials.* (A communication.) Dated February 11, 1863.

This invention relates particularly to the instrument known as a brace, used by joiners and other mechanics; and the improvements consist in attaching to the brace a spring, by means of a small screw; the said spring is slightly hollowed at one of its ends to receive a pin having a hollowed part to allow the passage of the bit or drill, which pin by means of the spring is forced through the socket of the brace, so that it may enter the groove cut in the head of the bit or drill, in order to secure the said bit or drill in the socket, and prevent its falling out. This is a great advantage, as well as a saving of time, and when the bits or drills have to be removed or replaced the hollow part of the pin is made to correspond with the hole in the socket. The sockets can be made of various forms, and either bored or slotted internally to gauges so that any kind of bit or drill corresponding with its intending socket may enter it easily. *Patent completed.*

371. J. Duckworth. *Improvements in the manufacture of paper.* Dated February 11, 1863.

This invention consists in mixing with the fibrous pulp commonly used in paper-making a suitable proportion of a grey or slate-coloured material found principally in the coal mines of Lancashire and other parts of Great Britain generally covering the seams of coal. The said mineral is principally composed of alumina, common clay, and shale, and is ground or pulped in any suitable manner. By this admixture the paper is made cheaper, of finer quality, and more susceptible of glaze than by the ordinary modes employed, and also forms various shades of colour without the aid of other colouring matters. *Patent completed.*

372. D. Radcliffe. *Improvements in valve taps.* Dated February 11, 1863.

This invention relates to that class of taps which have the valves closing with the stream or current of the water or other fluid they are intended to control; and although taps constructed according to this invention are specially suitable as ball taps, and lever-handle taps, they may be variously used or employed. The body of the tap—which may be of any desired form—has a seating therein for an ordinary or other valve, the spindle of which is carried through or elongated from both sides of the same. To the end of the spindle at the back of the valve there is secured by screw nuts or otherwise a diaphragm made of a sheet of india rubber or other flexible material, the circumference or edges of which is or are tightly secured between flanges or otherwire, and over this diaphragm there is a blank cap—that is, a cap without openings of any kind therein. Between the valve and the diaphragm the supply connection is made, so that, when the tap is closed, the fluid presses both on the back of the valve and on the diaphragm. That part of the spindle on the other side of the valve is in the nozzle or outflow passage, and it is to this part that a ball lever, weighted lever, or other arrangement to operate the valve is connected, thus rendering it necessary when the tap is being opened that the spindle and the valve should be moved in a direction against the flow of the fluid supply, and the diaphragm forced against the blank cap herein before mentioned. The connections of the operating lever may be made in any convenient manner, either to the end of the spindle outside the nozzle or discharge way, or to the said spindle through the sides of the said nozzle or discharge way. *Patent abandoned.*

373. C. P. Carter. *Improvements in road-making.* Dated February 11, 1863.

The inventor casts, moulds, or forms iron or similar hard metal into blocks or pieces of various shapes and sizes, and then places them together so as to form a road, consolidating the same with stone, concrete, or other material into a compact surface, having, however, good foothold for horses and other cattle. *Patent abandoned.*

374. R. Saunders. *Improvements in pavements and floors, which improvements are also applicable to stairs and steps.* Dated February 11, 1863.

This invention consists in using double angle iron, or iron or other hard metal, bent, rolled, or otherwise prepared, so as to form a trough or receptacle, which receptacle the patentee fills with wood or other material, he

prefers to make the surface of the wood to overlap the top edges of the metal; or he can use the wood thus shaped without the trough or receptacle. He causes each of the troughs or receptacles, fitted as aforesaid, to have spaces between them when laid down, in order to facilitate surface drainage: or he places wood blocks or timbers together, connecting them by iron or metal connections, so as to form a mass or masses of pavement of equable surface. He sometimes places sleepers beneath the said troughs or receptacles filled as aforesaid. Or he uses brick-work, stone-work, or cement in substitution for the sleepers. *Patent completed.*

375. W. SYMINGTON. *Improvements in weaving and in apparatus therefor.* Dated February 11, 1863.

The patentee claims using a single leaf of heddles or healds in combination with jacquard harness, or other equivalent means, in the weaving of muslin or leno curtains, or similar fabrics. *Patent completed.*

376. R. A. BROOMAN. *Improvements in photographic apparatus.* (A communication.) Dated February 11, 1863.

This apparatus enables the manipulator to operate in full light upon damp collodion, to sensitize the glass, and to finish the proof in the light. The apparatus does not alter the negative now used, but it serves as an auxiliary to it. In the apparatus the following characteristic elements are combined:—The employment of two vertical and independent bath vessels, arranged to allow of the glasses being easily plunged therein; one vessel, containing the bath of silver for sensitizing the damp collodion, may be of gutta percha, hardened rubber, or other material having no action on the bath; the other, containing the iron bath for developing the picture, should be of yellow or orange-coloured glass; if made of any other material, it should be lined with yellow coloured glass. There is a frame for holding the glasses to be exposed, capable of being opened and closed at bottom by withdrawing or inserting a sliding bar. There is a second frame for holding the collodionized glass in the former frame, which second frame is styled the plunging-frame, because it is used for introducing the glass into the bath vessels, entering also with it; it is insulated from the first frame, and may be passed through it; a piece of catgut is attached to the plunging frame to raise and lower it into and out of the baths. *Patent completed.*

377. E. HUMPHRYS. *Improvements in apparatus for steering ships.* Dated February 11, 1863.

For the purposes of this invention, the inventor employs hydraulic power, there being a cylinder and piston connected with the tiller, and giving motion thereto, the cylinder being supplied with water or liquid under pressure from an accumulator or chamber, in which it is kept at a constant pressure, and into which the liquid is pumped by the engines of the ship; so far the arrangement does not differ from what has before been practised. According to this invention, however, on the bridge of the vessel or other place from which it is desired to steer the ship, and at a distance from the steering cylinder, the inventor places a slide valve contained in a chamber, and this is connected with pipes which are led away to each end of the distant cylinder. The valve chamber also communicates with the accumulator. The valve is connected to the steering lever, and is moved by it, so that, when the steering lever is moved towards either side, it allows the water or fluid to flow from the accumulator to the steering cylinder, so as to produce a corresponding motion of the rudder. When the valve allows the water or liquid to flow to the cylinder on one side of the piston, it allows it to escape from the cylinder on the other side of the piston, but when the steering handle and valve are placed centrally, the liquid is locked in the cylinder, and the rudder is held stationary wherever it may have been placed. The two pipes are laid from the valve chamber to the steering cylinder in a groove in one of the deck planks, and the groove is covered with metal plate, so that the pipes may be out of the way of injury, and yet readily accessible; and in the same grooved plank a rod is placed which moves with the rudder and actuates an indicator placed near the steersman. *Patent abandoned.*

378. H. WYCHERLEY. *Certain improvements in the construction of, and mode of applying, wings or dirt screens over the wheels of carriages.* Dated February 11, 1863.

The patentee claims the "distinct" use of auxiliary springs secured to the axle for supporting the wings or guards of carriages, in contradistinction to their being supported or connected with the bodies of such carriages. *Patent completed.*

379. F. OPPENHEIM. *Making a plastic compound for dental purposes, to be used instead of wax, gutta percha, or gums, in taking the impression of the mouth.* Dated February 12, 1863.

This invention consists in taking white French chalk, china clay, or any other mineral, provided it be not injurious to the mouth, reducing it to an impalpable powder, adding a little colouring matter, and mixing it thoroughly with oil until brought to the consistence of putty or dough, and employing it in the way well known to dentists for taking the impression of the mouth, instead of the wax, gutta percha, gums, or other substances used hitherto. *Patent abandoned.*

380. E. KEMP, J. NEEDHAM, and O. ROBINSON. *Certain improvements in self-acting mules for spinning.* Dated February 12, 1863.

This invention is designed to dispense with, and supersede the use of, the sector, as hitherto employed in mules to actuate the fallers, and consists in a novel arrangement and combination of apparatus. Upon the inclined surface of the copping rail a small bowl runs, which is attached by means of a stud or bracket to one end of a lever, having its fulcrum on the framing of the spindle carriage, the opposite end also being furnished with an adjustable bowl which comes beneath and presses against a projection attached to a vertical lever connected with the faller shaft, such pressure being caused by the action of the first bowl on the inclined surface of the copping rail as the mule carriage runs in. Whilst the fallers are guiding the yarn and shaping the cop, the adjustable bowl is retained under the said projection, thereby affording steadiness and certainty of action to the fallers, the release of such bowl being effected by means of a horizontal bar sliding in bearings on the top of the spindle carriage, such bar being in a line with the lower end of the vertical lever, and so arranged that, when the carriage runs in, it shall displace the vertical lever, and thereby allow the fallers to rise, placing them again in position for action. *Patent abandoned.*

381. A. MORTON. *Improvements in lawn-mowing machines.* Dated February 12, 1863.

This invention relates to improvements in lawn-mowing machines, and consists—1, in the arrangement of the driving gear. For this purpose the inventor fixes on, or casts in a piece with the side frame of machines, an internal toothed circle, which works a small pinion mounted on the crank pin of a crank mounted on and revolving with the main axle of the machine, which crank pinion is thrown out or into gear by a sliding clutch in the usual way. This crank and pinion again take into a second pinion mounted loose on the main axle outside the framing; of a piece with or fixed to this pinion is a larger spur wheel which takes into an intermediate stud wheel, transmitting the motion to a pinion fixed on the axis of the revolving cutters. By this arrangement of the gearing, a high speed is obtained in the cutter with a simple and compact arrangement of the gearing. The second part of the invention consists in the use of india rubber, gutta percha, leather, or any other suitable substance or composition as a material for the formation of the toothed gearing or surface communicating the motion which it transmits without noise. *Patent abandoned.*

382. W. CLARK. *Improvements in the bearing surfaces of shafts and other axles.* (A communication.) Dated February 12, 1863.

This invention relates to the application of hard metal spheres for transmitting the load weight of journals and shafts. These spheres are contained in a suitable box, and the journal, in its rotating, produces a rolling movement in the whole of the spheres, thus creating a rolling friction in lieu of the ordinary sliding or rubbing friction of journals and shafts in their bearings. *Patent abandoned.*

383. S. H. PHILLIPS. *An improved fastening for purses, portmonnaies, pocket-books, bags, reticules, and such like purposes.* Dated February 12, 1863.

The inventor proposes to take a flattened tube of thin sheet iron or other metal, in which he places a slip of brass or other metal forming a slide, and having cut therein a slot through which a pin projects being inserted and fixed through the sides of the tube; the slide projects beyond one end of the tube, and extends somewhat below the middle portion thereof, and then compresses a small spiral spring fixed near the opposite end of the tube, the spring maintaining the position of the slide against the pin which prevents the slide being pressed out of the tube. The central portion of the tube is pierced with an aperture, half of which is closed by the slide, and the remaining half exposed by reason of a rectangular space cut in the slide. This portion of the fastening is to be fixed within the front lining of the bag, purse, portmonnaie, or other article, and a lock plate should be fixed outside a suitable aperture therein, being arranged to expose the aperture in the tube within. To the flap of the purse, bag, or portmonnaie a projecting stud or pin is fixed, having a notch cut therein on one side, and its extremity presenting an angular or wedge-shaped surface. It will be obvious, when the stud is pressed into the lock-plate by the closing of the flap, that it will enter the orifice in the tube, and, coming in contact with the side of the aperture in the slide, will force it towards the spring, the slide then running back into the notch and fastening the bag or purse. *Patent abandoned.*

384. S. LAMB and J. SPINK. *Improvements in machinery for tenoning, grooving, sawing, and otherwise cutting wood.* Dated February 12, 1863.

The following are among the prominent features of this invention:—In constructing a tenoning groove and sawing machine, the inventors employ two parallel axes, so arranged that the distance between them can be adjusted, each axis for this purpose being mounted on a slide on the main frame. The slides are capable of being traversed by screws, each slide having two screws, one near each of its ends, and these screws are turned simultaneously by means of bevelled gear from an axis at right angles to them. These parallel axes carry the tenoning cutters; the cutters for cutting the flat of the tenon are of ordinary construction; but to cut the shoulder of the tenon, in place of employing straight cutters sharp at the end, as is usual, the inventors employ discs of steel sharpened all round; these are each connected with the cutter head by a central screw, so that, when by use one portion of the cutting edge of the disc has become dull, another portion can be brought up by turning the disc partly round, and this without in any way interfering with the adjustment of the machine. In order that tenons may be cut in which the shoulder on one side of the piece of wood is further from the end thereof than the shoulder on the other, they make one of the cutter heads to slide longitudinally on its axis. In order to obtain this adjustment, they prefer to employ a screw passing through the head, and entering a hole tapped in the end of the axis, and they clamp the head in its proper position when it has been adjusted. According to this invention, they mount the cutter axis in conical bearings, there being two cones on each axis to run in the bearings, and one of these cones is adjustable, so that it can be set up to compensate for wear. The table for presenting wood to the tenoning cutters is capable of being moved to and fro on guides fixed at right angles to the cutter axes. *Patent abandoned.*

385. G. H. BIRKBECK. *Improvements in processes or means employed for separating or extracting silver or other metals from lead.* (A communication.) Dated February 13, 1863.

This invention refers to a former patent dated October 23, 1861, No. 2643. The employment of a bath of sulphuric acid, the inventor states, is preferable to that of muriatic acid, because of the formation of chloride of silver, which is difficult to decompose by heat without loss. The bath of sulphuric acid, on the other hand, gives place to water charged with sulphate of zinc, and gives it up at a profit on the cost of the process in case of any demand in the locality for this sulphate. In the absence of such demand, it can be converted into oxide of zinc, if it is more marketable. The second part of these improvements relates to the economy of zinc employed, and consists in restoring to the desilvering boiler, for the subsequent operations, a certain quantity of zinc bearing lead; that is to say, lead susceptible, on account of its small proportion of silver and its great proportion of zinc, to take up a part of the silver or lead of the said boiler. *Patent completed.*

386. S. M. INNES. *Improvements in the construction of pianofortes.* Dated February 13, 1863.

This invention consists in constructing pianofortes so that by their mechanism they will enable performers to play any piece of music written in any key of sharps or flats, as if it were written in any lesser number of sharps or flats, or even in the key of C, the actual key not being changed, but by the employment of stops a change takes place, and all or as many as are required of the notes of the black keys are produced by the white ones or natural keys, and the accidentals (if any) in keys from one to five flats and one to five sharps, can be produced by striking the half note below for flats, and above for sharps, the naturals being played in flat keys as a flat, in sharp keys as a sharp, accidental sharps and flats as usual. For keys of seven flats and seven sharps, the key-board is moved up half a tone for sharps, and down half a tone for flats, the accidental naturals being played on the half note above in flats, and the half note below in sharps. For keys of six flats and six sharps, the key-board is moved as for seven flats and seven sharps, and the seventh flat is made natural by pulling out a sharp stop, and the seventh sharp likewise by pulling out a flat stop. Also a moveable key-board is used, which can be shifted at pleasure (to use with or without the aforesaid) raising or lowering, as desired, the pitch of the music to be played, to suit the pitch of instruments and voices. *Patent completed.*

387. W. E. GEDGE. *Improved table apparatus for promoting the comfort of persons at sea.* (A communication.) Dated February 13, 1863.

This apparatus, which may be of any shape, and as ornamental as may be desired, is constructed as follows:—On two upright supports fixed to the table, and sufficiently above it to avoid touching it in the come-and-go motion, is a moveable axle to which is suspended a stand or tray, on which are placed the bottles, glasses, or other objects, and a weight in the shape of a moveable cylinder is carried at the lower end of vertical pieces for the purpose of always preserving the equilibrium of the entire apparatus when tossed about by the rolling of the ship. The axle of the apparatus must be placed parallel with the sides of the ship; nevertheless, when the inconveniences of pitching are to be avoided, the axle may be placed slightly slanting athwart-ship. The principle of this arrangement is, therefore, suspension rendered applicable—firstly, by the reduction of the radius of the segment described as much as possible, so as at the same time to reduce the come-and-go motion almost to nothing; secondly, by the position of the balance weight, the axle of which is parallel to the axle carrying the stand or tray, and is placed well in the centre of the lower extremities of the perpendicular pieces carrying it. The duty of this weight is not only to prevent the apparatus swinging about, but also to prevent it from capsizing; its weight must therefore be in proportion to that which the épergne or stand will have to carry. *Patent abandoned.*

388. J. JONES. *Improvements in the manufacture of lead, tin, and other metals, or amalgamation of metals of a like fusible nature, into sheets of any required thickness and length, and also coating one or both sides of pipes and sheets of lead and other metal, or amalgamation of metals, with tin or other substances, and in the apparatus connected therewith.* Dated February 13, 1863.

The patentee claims—1, The use of a vessel for containing the molten metal to be formed into sheets, which is closed at the top, and causing it to move on the piston or ram by hydraulic power, in place of moving the piston as heretofore, so as to allow the sheets or tubes of metal or amalgamation of metals to be formed by pressing the metal through dies in the side or sides of the vessel containing the molten metal, or through dies placed on the head of the fixed piston and passages formed there through, to allow the sheets to be delivered from one or both sides of the piston below the container, substantially and in the manner and for the objects described and set forth. 2, The use of a fixed or moveable piston fitted with forming knives or dies, and constructed with vertical passages and lateral ports for the formation of sheets of lead or other metal, or amalgamation of metals, as described and set forth, or any mere modification of the same. 3, The use of a fixed ram, in combination with moveable container having the dies or forming knives placed in the bottom or side or sides of the container, in place of at the top, as heretofore, substantially in the manner and for the purposes described and set forth. 4, Forcing out the molten metal or amalgamation of metals to be converted into sheets from the container, through suitable dies at or near the bottom thereof in a cylindrical or tubular form, and then receiving it on suitable mandrils, or otherwise cutting it open by fixed or moveable knives, saws, or other mechanical equivalent, and flattening it out into sheets by rollers, or in any other convenient way. 5, The peculiar mode and apparatus for tinning or otherwise coating as formed sheets of lead or other metal, or amalgamation of metals, as described and set forth, or any mere modification of the same. And, lastly, the general construction, arrangement, and combination of the various parts of the apparatus. *Patent completed.*

389. J. F. SPENCER. *Improvements in steam engines* Dated February 13, 1863.

This invention is not described apart from the drawings. *Patent completed.*

390. J. ROBERTSON. *Improvements in apparatus or means for printing woven fabrics by blocks.* Dated February 13, 1863.

This invention is not described apart from the drawings. *Patent completed.*

391. J. GRANTHAM. *Improvements in hydraulic presses.* Dated February 13, 1863.

The object of this invention is to vary the amount of power given out by a single ram in a hydraulic press, although the pressure of water or other liquid may be uniform. The first part of the invention relates to an arrangement by which the power exerted by the ram is increased at a certain distance or distances during the stroke, resulting in an economical process for packing or pressing any material into a smaller bulk, and which requires less pressure at the commencement than at the conclusion of the stroke, and especially useful where an accumulator is employed. In order to effect this object, the patentee constructs both the ram and cylinder in which it works of two or more diameters, each of which is provided with a packing of the ordinary kind. The ram has a telescopic shape, but does not slide within itself; its smallest diameter is first operated on by the water pressure, by which it is forced to a certain distance, when the next diameter is also operated upon, giving an increased force and, so on to the next, according to the number of gradations in the ram, the power being increased proportionately to the increased diameter of the ram. The spaces between those portions of the ram and cylinder formed during the traverse, but not yet supplied with the high pressure, are filled up by means of a flow of water at a low pressure from a pipe fitted with a self-acting valve, which closes immediately the high pressure is turned on, and prevents the water from receding. For the purpose of turning on the water from the accumulator or pumps to the increased diameter or diameters of the ram at the proper time and distance of traverse, the patentee arranges a pipe communicating either direct with the small end of the cylinder, or with a supply pipe, and fits the same with a stop valve and lever. This lever may be actuated in any convenient manner by the traverse of the ram, so as to set on the valve as required. Another convenient method for turning on the high pressure of water is by forming holes or longitudinal or diagonal slots for a certain distance on the side of the ram, so that, when it has traversed such distance, the water pressure may be communicated past the packing from the smaller diameter of cylinder to the next of larger size. The second part of the invention relates to an arrangement in which the power exerted by the ram is greater at the commencement of the stroke than at the conclusion. For this purpose he constructs the ram of a telescopic form, consisting of one ram sliding within another of larger diameter but of less length, the external ram sliding within a cylinder provided with a shoulder or stop; when the pressure from the accumulator or force-pump is applied, it operates upon and actuates both the rams, which traverse together a certain desired distance, until they arrive at a projection or stop, when the pressure actuates only the internal ram, which being of smaller diameter exerts a diminished force and requires less water. *Patent completed.*

392. W. ROBERTSON. *Improvements in machines for spinning and doubling.* Dated February 13, 1863.

This invention is not described apart from the drawings. *Patent completed.*

393. G. WRIGLEY and S. MORRIS. *Improvements in machines for spinning and doubling.* Dated February 13, 1863.

This invention is not described apart from the drawings. *Patent completed.*

394. O. H. HODGE. *Improvements in hat-brims, and in the apparatus or machinery used in such manufacture.* Dated February 13, 1863.

This invention is not described apart from the drawings. *Patent completed.*

395. J. A. SCHLUMBERGER. *Improvements in heating coal tar dead oils, and for producing phenic or carbolic acid.* (A communication). Dated February 13, 1863.

The object of this invention is to effect an economy in the manufacture of phenic or carbolic acid from dead oils, or thick heavy oils obtained from coal tar. To this end it is proposed to substitute lime for the potash or caustic soda which has been generally used for separating the said phenic acid from dead oils. *Patent completed.*

396. S. WHITAKER. *Improvements in indicating the positions or conditions of railway signals and points, and in the apparatus employed therein.* Dated February 13, 1863.

This invention relates to indicating the positions or conditions of railway signals and points. As applied to a lamp or night signal with a view to indicating to the signal man at a distance whether the lamp continues to burn or not, it is proposed to place inside the lamp, in any position which will insure its being heated by the same when burning, a piece of metal of any desired or convenient form, which will readily expand by the heat imparted to it. The expansion or contraction of this piece of metal is made to establish an electric contact, and complete a circuit from a battery through a galvanometer. For example, so long as the piece of metal is expanded by the heat, the current passes through the galvanometer, and the consequent deflection of the needle indicates that the lamp is burning; but should the light become extinguished, the cooling of the piece of metal and its contraction will break contact, and the circuit being interrupted the needle will return to its original position, again indicating to the signal man that the light is no longer burning. According to another part of this invention, it is proposed to connect railway points and crossings with a battery, and with suitable contact surfaces, so that, when the point is open or closed, as the case may be, a circuit will be established through a galvanometer, the needle of which will indicate the position of the points in connection therewith. The same arrangements for indicating the positions of the points are equally applicable for indicating the position of the day signals. By providing an ordinary signal with proper contact points, and connecting such points by wires with a battery and galvanometer at an adjoining station or intermediate point, the setting of the first signal is instantly indicated by the needle to the signal man of the second signal. *Patent completed.*

397. G. HASELTINE. *Improvements in lever horse-power machines, the cog-gearing employed being applicable to other machines.* (A communication.) Dated February 14, 1863.

The nature of this invention consists in a novel construction of the master wheel, and its arrangement in connection with the intermediate gear wheels; in rotating the main shaft with only the stepping for its bearing; in supporting the driver's seat on a standard that may be attached to or detached from the main shaft at the pleasure of the driver; in so constructing the machine that the dust and other foreign substances are excluded without the use of a casing; and in connecting the band wheel shaft with the tumbling shaft in such a manner that both rotate in one direction at unequal rates of speed. *Patent abandoned.*

398. R. BAGALEY. *Improvements in the construction of creels for warping machines, and other machines to which creels are applied.* Dated February 14, 1863.

The nature of this invention consists in making the bushes of creels of box or other hard wood, with a slot in which the spindle or bobbin peg revolves, and with a back to prevent the spindle or bobbin peg from moving endwise. These bushes are let into and secured to the uprights of the creel in the same manner as the glass bushes heretofore employed. *Patent abandoned.*

399. J. C. JEFFCOTT. *Improvements in the production and generation of gases.* Dated February 14, 1863.

The object sought to be obtained by this invention in the production of gas for lighting and heating purposes is, chiefly, the utilization of the heat now not used in steam or other furnaces, and open or closed fireplaces of every description. The means for effecting this object consist in introducing into the furnaces or fireplaces vessels of various forms, composed of cast iron, clay, or other metallic substances, and placed according to the construction of the said furnaces or fireplaces, and made to correspond with the furnaces or fireplaces now in use, or to be used hereafter, for these or other purposes, so as that the said heat may be used. The vessels to be generally used will consist of a retort or retorts, to be placed lengthways or otherwise over or at the sides, or as may best suit the fire bars of the different fireplaces, and in these retorts will be placed the various substances, animal, vegetable, or mineral, from which the different gases are to be obtained by distillation for lighting and heating purposes, and by the heat before referred to and not now used for these purposes. The gases, after being set free, are conducted by pipes to the condenser, which consists of two cylinders, one placed in the other, the outer one holding water; the gas, on entering, goes to the inner cylinder, which it fills, and is then driven by the hydraulic power to the gas holder, in its tank filled with water saturated with lime, and holding the salts of soda in solution, through which it passes, and by this means is perfectly purified and ready to be used. *Patent completed.*

400. W. C. PAUL and A. T. SHORE. *Improvements in the mode of constructing spring mattresses and other such articles for sitting and reclining upon.* Dated February 14, 1863.

For the purposes of this invention, in constructing a mattress or like article of furniture, two separate frames made of wood, metal, or other suitable material, of proper strength, are used and placed one over the other. On the bottom of one of these frames is placed a series of laths, made of deal or other suitable material, reaching from side to side of the frame, and placed at regular distances from each other, for the purpose of fastening and supporting the spiral springs used in making spring mattresses, and which are fastened to the laths by strong wire staples. The spiral springs to be used may be of three different sizes, the largest at the head, the medium in the middle, and the smallest at the foot of the mattress; the springs are arranged in these positions for the better and more easily sustaining the weight of the occupants. The upper frame is to be of the same size and shape as the bottom one, and placed over the bottom one, leaving about 7 in. space at the head, and about 5 in. at the foot. The tops of the spiral springs are all securely fastened to the upper frame by strong and suitable cords drawn from side to side of the frame, and tied on two sides of each spring over which it passes. The same is also done from head to foot, and may be also diagonally from corner to corner, the whole, when tied in this way, forming eight distinct and separate knots on each spring, and thereby firmly fastening all the springs in their proper positions to the upper frame. To keep this frame from turning over on either side, strong webbing is fixed on the corners of the top frame, and drawn down in the middle and fastened to the centre of the bottom frame on each side and end. The top frame and springs are then covered over with strong canvas, and tacked firmly to the frame, forming an even surface to receive the stuffing, which is to consist of hair, wool, cotton, or any other article usually adapted for the purpose, and is finally completed by an outside covering of ticking or other suitable material drawn evenly and tightly over the stuffing, and tacked to the outside edge of both top and bottom frame, and also tufted, or otherwise, as may be required or found necessary. For the purpose of raising the head of the mattress and giving it greater inclination, two leather straps and buckles are placed one at each side near the foot, so as to draw the two frames together, thereby giving the inclination best suited to the occupant, being particularly adapted for invalids. *Patent completed.*

401. J. S. GISBORNE and W. SIMPSON. *Means of rendering ships and other compasses insensible to local attraction.* Dated February 14, 1863.

This invention consists in passing a current of electricity from an ordinary battery through a coil of insulated copper wire wound around a hollow, conical, or semispheroidal compass box, or wound round a hollow, conical, or semi-spheroidal shaped dish encircling the compass box. In either of these arrangements the magnetic needle rests on a centre pin, or, when there are more than one, they are secured to the card or other part which rests on the pin in any usual way at a short distance below a straight line drawn horizontally across the upper termination of the said coil, and below the mouth or termination of the conical or semispheroidal shaped box or dish, the leading features of construction of compasses at present in use being retained. *Patent completed.*

402. H. DEMBINSKI. *A motive apparatus, and processes proper for giving to it a continuous motion and unlimited strength.* Dated February 14, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

403. W. BAYLIS and T. H. HOPWOOD. *Improvements in tongs or forceps for grasping articles out of reach of the hand.* Dated February 14, 1863.

This invention is not described apart from the drawings. *Patent completed.*

404. W. WOOD. *Certain improvements in cutting or producing screws or threads, and in apparatus connected therewith.* Dated February 14, 1863.

This invention relates to the cutting or formation of such screws, worms, or similar helical threads as are termed male or external screws. The apparatus consists in a novel arrangement of, and improvements upon, the well-known "stocks and dies," and is designed to render one "stock" available for three or more "dies." The improvements consist in the employment and use of equilateral triangles, or two four-sided pieces of metal, each side of which is to contain one-half of the screwing "die," so that, when two corresponding sides are brought together, the die will be formed at the middle or division when the two pieces come in contact, the triangular pieces being secured to a back plate by a central screw through each. A second part of the invention consists in a novel arrangement of apparatus for tightening and adjusting the "dies" as now employed in ordinary "stocks and dies," and which is also applicable to the adjustment of the before-mentioned four-sided pieces. At the end of the opening in the stock wherein the "dies" fit, a narrow slot is formed to receive a moveable nut, within which a screw works, terminating in a head which abuts against the back of the sliding "die," so that, by turning the screw out of the nut, pressure is exerted on the die, the nut and screw being readily displaced for the ready substitution of another die. *Patent abandoned.*

405. J. LEWIS. *Improvements in driving sewing machines.* Dated February 14, 1863.

This invention consists, principally, in driving sewing machines by means of coiled springs, or by coiled cords, chains, and weights, instead of driving them by means of a treadle worked by the foot, or by steam, or other similar power, as hitherto practised. *Patent abandoned.*

406. J. H. WALSH. *Improvements in breech-loading fire-arms, and in the cartridge cases to be used therewith.* Dated February 14, 1863.

This invention consists in a mode of opening and closing the breech without depressing the barrel, or thrusting it forwards, and yet allowing the cartridge to be pushed in straight from behind; and in the adaptation of a cartridge extracting power, quite independent of the barrel, and not, therefore, weakening the latter by cutting a slot therein, as is the case with ordinary extractors. The novelty in the cartridge case consists in clothing it with a thin layer of paper, silk, or other fibrous material, attached by a new compound, and in the peculiar arrangement of the nipple cover. The attachment of the hammer to the striking pin is also carried out in a novel manner, so as to draw back the pin without impeding the full blow of the hammer. *Patent abandoned.*

407. J. THORNE. *Improved apparatus for disengaging ships' boats.* Dated February 14, 1863.

This invention is carried out in the following manner:—To the keel of the boat two sockets are firmly bolted, and into these sockets are passed the lower ends of two suspending rods, the ends being formed with long slots, and the sockets provided with bolts passing through the slots in such a manner as to allow of the suspending rods having a certain amount of vertical motion in the sockets, but not of their being withdrawn entirely. At the upper end of each suspending rod is a slip hook, which is kept closed by a guard link attached by a rod to the socket, and sliding on the suspending rod. The boat is supported by passing two hooks attached to two blocks (running in the bight of the davit tackle falls) into the slip hooks at the upper ends of the two suspending rods. The stem and stern of the boat are supported by means of links or rods connecting them respectively to the slip hooks. When the boat is hanging at the davits, the suspending rods are held fast in the sockets by means of two locking bolts, both connected to one rod, the end of which is attached to a lever in the stern or other convenient part of the boat. When the boat is lowered into the water, upon pulling this lever, both bolts are simultaneously withdrawn, when the suspending rods slide in the sockets just sufficient to draw the guard links off the ends of the slip hooks, thus instantaneously disengaging the boat from the falls at both ends. *Patent abandoned.*

408. W. CLARK. *Improvements in the method of, and apparatus for, separating the fibres of straw, wood, and other vegetable substances, and extracting the gummy and colouring matters therefrom, to render them fit for paper stock, or for other purposes.* (A communication.) Dated February 14, 1863.

This invention relates to the separation of the fibres of vegetable substances, and the extraction of their gummy and colouring matters, by subjecting them to the action of water, brought to a temperature at which it boils under a pressure greater than that of the atmosphere, either with or

without the use of alkalies, or of rubbing, grinding, or beating devices, as an aid to maceration. *Patent completed.*

409. A. J. FRASER. *Improvements in window furniture or fastenings.* Dated February 14, 1863.

This invention consists of a metal or other suitable ratchet toothed rack, which the inventor applies to the inside of the window frame; this extends from top to bottom of the sash, one for each sash. This rack has its ratchet teeth so disposed that the horizontal part of each tooth is above. On the window sash he applies a spring bolt, which is so fixed as to abut its end against the rack, and by the pressure of its spring is kept up thereto, and is at the same time free to recede. The effect of this bolt is, that on raising the sash, the bolt slips over the inclined faces of the teeth, freely catching at each one, and preventing the sash again descending from any intermediate distance to which it may be raised, or at the full height. Thus, in opening a window, it is simply necessary to lift the window to the required height. If it be desired to lower the window, it is simply necessary to withdraw the bolt from contact with the rack teeth, and lower it down when closed. A hole is provided in the rack at that point to receive the end of the spring bolt, which shoots into such hole, and prevents the window from being again raised until the bolt is withdrawn, which, of course, can only be done from the inside. If it be desired to fix the window sash open a few inches, so that it cannot be further opened from the outside, he adds another bolt at the top of the sash, which is shot into one of several holes which receive it, and secure the window sash at the height desired. The advantage of this mode of fixing and supporting window sashes are—that the window cannot be opened from the outside, and that the counter-balance weights and boxes may be dispensed with for ordinary windows. *Patent abandoned.*

410. J. and H. HIGGINS. *Improvements in carding engines and in apparatus connected therewith.* Dated February 14, 1863.

The patentee claims—1, separating the impurities from the strippings of working rollers of carding engines, and conveying the cleaned material again to the main cylinder; 2, the application of a knife or blade, or a series of knives or blades, as described, to the clearers of working rollers of carding engines, for the purpose of conveying the impurities detached from such cleaners to the "licker-in," or to a roller where they are collected on its surface; 3, the mode described of driving the coiler shaft, and the employment of a strap which is shifted on to a loose pulley when the coiler shaft is required to be stopped; 4, the application of a second bearing to the brackets or stands of grinding rollers, for the purpose set forth; 5, attaching cylinders or rollers to their ends by contraction of the metal consequent upon cooling. *Patent completed.*

411. F. E. WALKER. *Improvements in the construction of breech-loading firearms.* Dated February 14, 1863.

This invention relates to a new construction and arrangement of the breech or action, and to a new and improved method of locking and opening the barrels of breech-loading guns, with which the cartridges known as the "Lefaucheux" cartridges are used. The improvement in the body of the action is such that the metal portions are so arranged and placed, that the gun-locks employed therewith may be of the bar pattern, "jointed" or fitted to the barrels and false breech, as in the muzzle-loading gun. The action is let into the stock, leaving the wood on each side, so that the locks may be let into the wood also, as in an ordinary muzzle-loading gun. The locking part consists of a steel tumbler carried by a pin, which passes through the body of the action, and the said tumbler has a lever or handle attached thereto, which, when the gun is closed, partly covers the guard of this gun, and by means of this lever giving motion to the tumbler, the barrels are opened or closed. A link connects the lever and the barrels in such manner that, by moving the lever forwards or backwards, the barrels are opened or closed, and when the lever is moved into position with the guard, the gun is locked securely, and in a more simple manner than by the means heretofore employed for this purpose. A safety is employed in combination with the parts previously described, whereby the triggers are firmly locked when the lever and tumbler are out of position, the stop or bolt of the safety being moved back when the lever is moved fully into position again over the guard. A spring catch or other simple fastening may be employed to secure the lever to the guard, or otherwise when the parts are closed. *Patent completed.*

412. J. MORGAN. *Improvements in embalming and preserving from decay human bodies and bodies of other animals; also pickling, curing, and flavouring animal bodies.* Dated February 14, 1863.

This invention consists in introducing into animal bodies preservative fluids, by means of the natural channels of the circulation, whereby structures are permeated by the fluids, whether for preservation for the purpose merely of embalmment, as in the case of human bodies where poisonous solutions may be used for the purpose of the dissecting room, or preservation in sealed cases of glass or other material in place of coffins, to be kept in mausoleums, vaults, or otherwise. It [illegible] consists in preserving, curing, or preparing animal b[illegible]tended to be used for food, such as beef, swine, and all the mammalia and birds (as well as the lower animals in some instances), by impregnating their bodies with salt, salt and saltpetre, salt and muriate of ammonia, or other salts, sugar, treacle, materials for preservative flavouring, colouring, medicating, and other purposes. The patentee proposes by this process to cure and preserve not only the bodies, but the hides of animals where it is desired. *Patent completed.*

413. J. H. JOHNSON. *Improvements in wrought-iron casements, and in the means for fastening the same, which improvements are also partly applicable to the framework of glass doors, conservatories, and similar structures.* (A communication.) Dated February 14, 1863.

In carrying out this invention, as applied to a French casement, the two side frames are rolled of an angled form, and have strips of wood secured to them which fill in the aperture in the masonry to which they are to be applied. The bottom of the sash frame consists of a bar curving outwards, so as to carry off the rain, and is secured at each end to the side frames by rivets, a similar mode of attachment being employed in securing the ends of the top part of the frame, which is in the form of a flat bar, having a raised rib or web rolled thereon near its lower edge on the inner side. Each sash is hinged to the frame by having tubular sockets screwed thereto, which drop into hinge pins in the frame, a hinged piece capable of being turned up when required serving to lock the sockets down upon the pins, or to release them when the sash is to be lifted off its hinges. The bottom bar of the sash is connected with the vertical bars by a mortise and tenon joint, and a somewhat similar plan is adopted in the upper bar, which plan is also used for the intermediate bars. The bottom bar curves outwards so as to throw off the rain, and a flat grooved bar is rivetted to it, which closes against and interlocks in the bottom bar of the window frame, a strip of india rubber being interposed to keep the sash weather-tight. The outer edges of the vertical sash bars are rebated, so as to close over two faces of the side bars of the frame, and the two adjoining vertical sash bars are bevelled in order to fit accurately together when the casement is closed. A longitudinal groove or channel is made in one of these bars, into which a strip of india rubber is inserted, for the purpose hereinbefore described, a corresponding rib and groove on the opposite bar locking into and bearing upon the india rubber in the groove of the bar last referred to. The window frame is kept closed by an "espagniolette," or French casement fastening, the rod of which is fitted to the sash frame by means of two hinges let into the frame. It is provided at the top and bottom with a hook, which hooks, when closed, engage into corresponding notches in pieces attached to the opposite sash. Through the centre of the rod is passed the spindle or axis of the handle, on the end of which is fitted a latch which, when the handle is in a vertical position, presses upon the vertical bar of the opposite sash, and thereby causes the two sashes to bear throughout their entire length against the sash frames. *Patent completed.*

414. M. OBREN. *Improvements in the construction of gasholders and in the mode of rendering gasholders self-acting.* Dated February 16, 1863.

Great inconvenience (and often danger) arises from closing the wrong valve in changing from one gasholder to another, and more especially from a heavy one to a light one, for, on opening the inlet of the light one the gas from the heavy one passes into it before the outlet of the heavy one is closed. These difficulties may be avoided, and the gasholders rendered self-acting, by fixing to the guide bars of the gasholder, to the columns thereof, or to the gasholder, or to any other convenient and suitable place, stops or guards, either at the top or bottom of the same, to catch the guide rollers or other portion of the gasholder, so as to stop the ascent of the gasholder on reaching the required height; the valves of all the inlets and outlets of the gasholders being open the lightest gasholder will fill first, then the next lightest, and so on in succession, until the whole of the gasholders in action are filled; during the supply the heaviest gasholder will discharge first. This mode of construction or adaptation will answer for any number of gasholders, however far apart, care being taken to stop off each gasholder with sufficient seal, with the exception of the heaviest one, which should not be stopped off at all, so that it may "blow" when all the gasholders are full. The inlets and outlets being all open, any increase in the bulk of a full gasholder in sunny weather will pass through the outlet, and go away with the "make" to the gasholder then filling. *Patent abandoned.*

415. J. W. CROSSLEY. *Improvements in press papers, and in the method or means of drying them and other similar sheets of paper, applicable also for the drying of woven fabrics, yarns, wool, cotton, or other fibrous substances.* Dated February 16, 1863.

This invention consists—1, in having press papers coated or covered with tin foil or other metal in thin leaves or layers, or an alloy of tin and any other suitable metal, or with other alloys, mixtures, or amalgams capable of producing metallic surfaces thereon. The second part of the invention consists in the employment of a series of cylinders heated by steam, or other heating media, and two endless aprons or cloths which pass over or partly around and in contact therewith, in such manner that press papers or other sheets of paper may be placed betwixt and carried or conducted thereby over and around or in near contact with each of the said cylinders in succession by which they are dried. The said series of cylinders or drying machine the patentee encloses to prevent radiation of heat, and he has a chimney or opening at the top (which may be connected by a pipe to the boiler chimney, with openings at the bottom to admit air, which may be first heated), by which means a current will be produced betwixt the cylinders, carrying off the vapours, thereby materially assisting in the process of drying. *Patent completed.*

416. C. D. ABEL. *An improved omnibus.* (A communication.) Dated February 16, 1863.

The patentee claims the construction of omnibuses having a double body or two compartments side by side, and carried by two sets of three wheels, one of each set being of a large diameter and placed centrally, so as to run in grooves formed between the two compartments. *Patent completed.*

417. Mr. C. MCENTEO and T. WITHERS. *Improvements in locks.* Dated February 16, 1863.

We cannot here give space to the details of this invention. *Patent completed.*

418. J. B. WATTS. *Improvements in the manufacture of matchets and swords.* Dated February 16, 1863.

In carrying out this invention, the inventor employs bars of steel of the kind commonly employed for the manufacture of matchets, and known in commerce as matchet steel. The said matchet steel is about the width of the matchet to be made, and is rolled of the form of the middle part of the blade of a matchet. The said matchet steel is cut into the required lengths by oblique cuts or divisions, and one end of each piece of steel is formed into the tang, and the other end into the point of a matchet by means of rolls. The tang is formed at that end of the piece of steel which forms an obtuse angle with the thick or back edge of the said piece of steel. In forming the said tang the inventor employs a pair of rolls, one or both of the said rolls being slightly eccentric to their axes; one of the said rolls has a portion of its cylindrical surface cut away to permit of the introduction of the piece of metal between the rolls. The heated end being passed between the rolls, the thick or back edge is elongated more than the thin edge, and the tang edge is thus made of nearly the same thickness, and of nearly the same length, on both edges. The tang is completed in the ordinary manner. In making the point end of the matchet, he first flattens and tapers the back edge by cross-rolling, and afterwards curves the required part of the matchet. This he effects by means of rolls, the acting surfaces of which are slightly inclined to one another. In inserting the piece of steel between the rolls, the edge which is to be curved of a convex figure is turned towards the ends of the rolls where their surfaces are nearest together. The matchet is finished in the ordinary manner. He forms the points of swords by the process described with reference to the points of matchets. *Patent abandoned.*

419. H. SMITH. *Improvements in apparatus for feeding horses.* Dated February 16, 1863.

This invention consists in arranging and applying apparatus to mangers, or to the troughs or vessels where horses are fed, in order that the food may be gradually supplied by a measured time to such mangers, troughs, or vessels, and so as to allow and ensure a reasonable time for the horses to eat their food. The arrangement of apparatus employed in carrying out this invention may be varied, but it is preferred to have a tube or shoot to each manger or vessel descending from a hopper or other containing vessel wherein the quantity of food for a feed is placed, and from which it is allowed to descend into the manger, trough, or vessel, the descent or speed of supply being regulated by a valve or slide, or other instrument, the action of which may be regulated by a falling weight or spring, or by other suitable means. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated June 27, 1863.

1615. G. Clark, 30, Craven-street, Strand, gentleman. Improvements in the construction of guns and projectiles, and of carriages, platforms, and shields for working and protecting guns.

Dated July 22, 1863.

1834. C. Senior, Dead Waters, near Huddersfield, engineer. Improvements in means or apparatus for closing, punching, and rivetting hose-pipes of leather or other substances, applicable also for punching and rivetting mill bands or driving straps, and similar purposes.

Dated July 28, 1863.

1870. M. Cockerill, 3, Munden-terrace, Hammersmith. The improvement of mortise and other door locks and latches.

Dated August 6, 1863.

1937. J. E. Dowson, 4, Victoria-street, Westminster. A new application of rolled metal plates to the formation of roadways, bridges, tramways, and other structures.

1943. W. Clark, 53, Chancery-lane, engineer. Improvements in taps or stopcock apparatus. (A communication.)

Dated August 10, 1863.

1967. J. A. Fullerton, Manchester, iron merchant. Improvements in the method of fastening hoops for packing bales, and in the machinery or apparatus employed therein.

Dated August 17, 1863.

2038. H. A. Bonneville, 24, Ru du Mont Thabor, Paris, France, and 38, Porchester-terrace, Bayswater. Improvements in engraving. (A communication.)

Dated August 18, 1863.

2044. J. Broadley, Saltaire, near Bradford, overlooker. Improvements in means or apparatus employed in weaving.

Dated August 21, 1863.

2077. R. Thompson, New Charlton. Improvements in machinery for planing curved, curvilinear, irregular, and other forms in iron, steel, and other metals.

2082. J. B. C. Lange, Paris, householder. An improved apparatus for indicating or registering the speed or distance travelled by vehicles, carriages, and such like, which said apparatus is also applicable to engines, water-wheels, and prime motors of any description.

Dated August 25, 1863.

2099. A. Hett, City, doctor of medicine, and F. W. Basset, Camberwell, civil engineer. Improvements in preserving animal substances, and animal and other substances used for food.

Dated August 26, 1863.

2106. J. L. Kessler, Paris, France, engineer. Improvements in apparatus for evaporating and distilling.

2107. S. Fattorini, 3, Rue Joubert, Paris, optician and mathematician. A new division of time, and the application thereof to mathematical and other instruments.

Dated August 27, 1863.

2118. J. Ward, Liverpool, merchant. Improvements in diving apparatus.

2120. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in breech-loading firearms. (A communication.)

Dated August 28, 1863.

2122. G. Davies, Serle-street, Lincoln's-inn, civil engineer. Improvements in the manufacture of iron and steel from the cinders and refuse of puddling and other furnaces, and from certain kinds of ores. (A communication.)

2124. J. Shaw, Junction Implement Works, New Wortley, Leeds, implement maker. Improvements in machines for cutting or reducing turnips or other roots as food for animals.

2126. E. Amourous, 4, South-street, Finsbury, gentleman. Improvements in apparatus for separating solid from fluid fecal matters.

2128. J. Alison, Reigate, gentleman. Improvements in apparatus for tilling land, which improvements are chiefly applicable when steam power is employed.

2130. J. Walls, Farington, near Preston, engineer. Improvements in steam boilers, and in apparatus connected therewith.

Dated August 29, 1863.

2134. T. Williams, Manchester, tobacco manufacturer. Improvements in machinery or apparatus for crushing and flattening the stalks of tobacco and other substances.

2138. D. Speirs, manufacturer, A. Boyd, pattern maker, and J. Kirkwood, weaver and mechanic, Paisley. Improvements in looms for weaving.

2140. F. C. P. Hoffmann, Newgate-street, engineer. Improvements in shears for cutting metal and other substances.

2142. A. Rowland, Glasgow, merchant. Improvements in evaporating fluid solutions, and in the machinery, apparatus, or means employed therein.

2144. L. E. C. Martin, 32, Albion-street, Hyde-park. Improvements in apparatus for generating steam and for generating gases to be used for heating steam boilers, and for other purposes.

Dated August 31, 1863.

2146. H. E. Kramer, Leipsic, Saxony, printer. Improvements in printing in colours pictures or devices to be used in ornamenting porcelain, stoneware, earthenware, or any other substances where the colours can be annealed or melted or burnt in.

2150. W. E. Gedge, 11, Wellington-street, Strand. An improved watch. (A communication.)

2154. G. B. Pettit, Oxford-street, gas engineer. A method of preparing mica and talc in order to render them applicable to articles of wearing apparel and to ornamental purposes.

Dated September 1, 1863.

2162. G. T. Bousfield, Loughborough-park, Brixton. Improvements in the manufacture of illuminating gas. (A communication.)

2164. G. W. Ewens, Sherborne-lodge, Doris-street East, Kennington-cross. Improvements in the manufacture of wadding paper and felted fabrics, and in the preparation of vegetable fibres to be used in such manufactures.

Dated September 2, 1863.

2166. J. Lewis, Manchester, engineer. Certain improvements in machinery or apparatus for preparing and drying clay, and also in machinery to be employed in the manufacture of bricks and tiles.

2170. C. H. Corlett, Güstrow, in the Grand Duchy of Mecklenburg Schwerin, civil engineer. Improvements in valves, taps, or cocks.

2172. F. C. P. Hoffmann, Newgate-street, engineer. Improvements in machines for crushing hard substances, for washing ores and minerals, and for separating earth and earthy matter from solid substances.

1731. R. and W. Hawthorn. Working of railways.
1791. N. Thompson. Boat-building, and machinery for shaping wood therefor.
1807. F. J. Mavor. Horse shoes.
1962. J., J., A., and W. Thorton. Apparatus for producing looped fabrics.
2059. T. Howard. Spinning fibrous substances.
2072. W. E. Newton. Manufacture of cartridges. (A communication.)
2087. L. E. C. Martin. Heating and purifying water.
2095. A. Capello. Glazing leather.
2102. J. W. Friend. Gas meters.
2144. L. E. C. Martin. Generating steam and gases to be used for heating steam boilers, or for other purposes.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed September 11, 1863.

608. P. Adie.
663. J. Cassell.
665. W. R. Mulley.
666. H. Wilson.
672. J. Renshaw.
673. W. Rossetter.
674. F. B. Kraushaar.
675. H. D. and J. W. Taylor.
679. J. Polkinghorne.
680. H. B. Barlow.
687. J. H. Johnson.
692. J. Page.
695. R. Alexander.
699. J. Walworth.
703. T. W. Willett.
709. W. G. Eavestaff.
712. W. H. Atkinson.
713. W. E. Gedge.
715. J. Cox.
719. W. Symington.
720. W. O. Wild and J. H. Randel.
721. W. Donbavand and D. Crichton.
723. R. A. Brooman.
724. F. R. H. Chandler and J. G. Richmond.
727. B. Wren.
729. T. Oldknow.
737. H. O. Haughton.
751. J. Brigham and R. Bickerton.
767. W. Clark.
773. A., J., and J. Topham.
790. M. L. Parnell.
807. J. King and T. H. Marshall.
832. H. Hamer.
833. J. M. Dunlop.
838. M. Henry.

LONDON, FRIDAY, SEPTEMBER 25, 1863.

AMERICAN HEAVY ORDNANCE.

THE construction of heavy ordnance suited to meet all the requirements of practical warfare, presents one of the most difficult problems which task the inventive powers of the men of the 19th century. The solution of any question depends on the accurate understanding of everything connected with it; and even comparative ignorance on any one division of a subject must materially invalidate the results obtained by calculation or experiment from the rest. We know a great deal about the strength of materials, the action of gunpowder, the flight of projectiles, and the exigencies of actual service; but we do not yet know enough, and as a result, we have failed in the construction of exceptional guns. We do not possess at the present moment a single gun capable of throwing a shot over 100 lb. weight, which is thoroughly reliable, or on which we could depend for half an hour in action. Not only the manufacture, but the working of large guns, even of the simplest form, is attended with difficulties of the gravest kind. And these obstacles to the general introduction of heavy ordnance, are increased a hundredfold by complicated breech-loading machinery, deemed indispensable, obtained at a vast expense, and usually found wanting in the day of trial. The largest guns ever used are at present to be found in the American navy. We referred last week to some of the practical details of their manufacture; and the subject is so important, that we willingly return to it, believing as we do that information concerning it, is of very great importance as a guide to our future proceedings.

The breech-loading principle is generally ignored throughout the States. A few small guns on Whitworth and Armstrong's principle, or something analogous, may, it is true, be found in both the contending armies. Our American friends do not believe in them, however, and eschew them when they can obtain anything else. The favourite naval guns are Parrott's and Dahlgren's; the latter are pretty well known. The most usual size is the 8 in. shell gun, with a length of bore of 100·3 in.; weight, 63 cwt. These guns, placed 9 ft. above the level of the water, throw a shell 1,776 yds. at 5 deg. elevation, with 9 lb. of powder. Much less is known of the Parrott guns; and as they are beyond dispute the best in the American navy, we do not hesitate to give our readers some information regarding them, on the accuracy of which we can implicitly rely.

The Parrott guns are usually made of the sizes 100, 200, and 300-pounders. The first has a bore 6·4 in. in diameter, and 130 in. long. The usual weight of this arm is 9,700 lb. The charge consists of 10 lb. of powder, and a conical projectile weighing 100 lb. The rifling consists of ten grooves, one-tenth of an inch deep, and exactly an inch wide. The lands and grooves are, as a principle, made as nearly as possible of the same width, no matter what the dimensions of the gun. The 200-pounder weighs nearly 8 tons, is 136 in. long, 8 in. bore, throwing a 150 lb. to 175 lb. shot with 16 lb. of powder. The bore is rifled with 11 grooves, similar in every respect to those of the 100-pounder. The 300-pounder 10-in. gun weighs over 11 tons, has a bore 144 in. long, and throws a 250 lb. shot with 25 lb. of powder; 14 grooves. The twist of the grooves is rather slow, being—in the 100-pounder, one turn in 18 ft.; in the 200-pounder, one turn in 23 ft. We cannot state the precise twist of the largest Parrott guns; but we believe it to be the same as that employed in the 200-pounder. The range of the 100-pounder is 5 miles, with 38 deg. of elevation, and the service charge.

The Parrott shot is a conical projectile, with rather a sharp head. It fits the chase of the gun pretty accurately, resting on the lands. A dove-tail groove is turned in the hinder end of the shot, about 2 in. wide and rather more than an inch deep towards the forward end. Into this groove is cast a ring of soft brass. The surface of the groove is "pecked" or roughened all over, so that the ring—which is just the size of the bore of the gun—cannot turn on the shot. The explosion of the charge "upsets" the brass ring into the shallow grooves, imparting a motion of rotation to the shot. Any effect similar to "leading" is of course impossible, and the gun is in consequence loaded with as much ease as a smooth-bore, while the brass sabot effectually precludes windage; being upset so thoroughly as to fit the bore mathematically, without any injurious friction. To this, doubtless, the vast range of the gun, with small charges, is directly attributable. Parrott ordnance is invariably constructed of cast iron, usually on the "Rodman" principle, already referred to in our previous number, strengthened with a reinforce, composed of a single-lap welded wrought-iron ring, extending from the breech to within a foot of the trunnions. It must be remembered that the gun is not cut away to receive the reinforce, which is shrunk on hot, turned and finished afterwards. Ordinary percussion fuses have been hitherto used for the shells. The great success of those guns, the facility with which they are loaded, their vast range and great accuracy, entitle them to a first rank as a military or naval weapon, and demonstrate clearly, that enormous charges of powder are quite unnecessary to the performance of a rifled cannon, when the proper conditions, regulating the flight of the projectile and its passage through the bore of the gun, are carefully observed. The employment of large quantities of powder is simply a clumsy expedient to counteract the evils resulting from an improper system of rifling and a faulty construction of shot. Large cannon never can succeed while the powder burned at each discharge is as much as one-third or one-fourth of the weight of the projectile. So thoroughly imbued with this conviction are American artillerists, that they have initiated some very remarkable experiments, with a view to concentrate the force of reduced charges of powder on the projectile with a proportionate diminution of the strain on the gun. A 7-in. gun was loaded with the full charge of powder, made up in a cartridge, 6 in. in diameter; so prepared, that when placed in the gun, a clear space of half-an-inch remained all round, between its circumference and the chase. The shot was then rammed close home on the cartridge, and the gun discharged with the following remarkable result. The initial velocity of the shot remained precisely the same, as though discharged in the ordinary way, while the strain on the gun was reduced nearly one-half as evinced by the pressure plug at the breech! Repetition has only confirmed the truth of the result obtained by the first experiment. The air cushion left between the powder and the bore, apparently protects the gun from the percussive force of the exploding powder, to which the shot is, of course, fully exposed. The entire phenomena afford a remarkable confirmation of the truth of the views expressed by Mr. Lynall Thomas on the action of exploding gunpowder. We have no doubt that the conduction of a similar series of experiments in this country would be fraught with the best results. After all, our Government has done little or nothing to determine the best form for a gun externally, or the real action of the gunpowder exploded within it. All the information we have on these subjects is due, in a primary degree, to private individuals; those having authority confining their attention almost exclusively to the rifling, the shot, and the mode of loading, while the resisting powers of the gun have either been left to chance, or sought for in the use of better material, almost without regard to its proper distribution. Dahlgren literally took a diagram of the forces developed within his first guns by drilling a number of small holes in a continuous line from breech to muzzle, in the side of a gun. Each of these holes was fitted with a pistol barrel or tube, screwed in, of such length that the distances from the bore of the cannon to the ends of the tubes were all precisely alike. These tubes were each loaded with a single ball, which, on the discharge of the cannon, was expelled with a force proportionate to the pressure of the gases at each part of the length of the gun. This force was measured by the depth to which the pistol balls penetrated an oak screen suitably placed to receive them. In one experiment the force was found to equal 3,000 lb. on the square inch close to the muzzle of an 8-inch gun with the service charge of powder and shot. The great efficiency to which American ordnance has attained is certainly due to a carefully conducted series of experiments, commenced years ago and continued to the present moment. The admirable simplicity of the service guns renders them thoroughly reliable, while the cost of their manufacture is extremely moderate.

Quitting the subject of rifled guns, we find much to interest in the colossal smooth-bores which perform their duties on the decks of the "Monitor." These guns are 13 ft. long in the bore, and carry a 15-in. spherical shot, called solid, but really containing a cavity 4 in. in diameter, which secures the solidity of the iron surrounding it by equalizing its contraction. These projectiles weigh 425 lb. The service charge of cannon powder is 35 lb. only, but cake powder is sometimes employed in 50 lb. charges. 15-in. shells weigh 350 lb. The initial velocity of shot thrown from these guns seldom exceeds 1,000 ft. per second; in consequence, they are far more terrible in name than in reality. The turrets in which they are placed are built up of a large number of superimposed iron plates, seldom more than 1 in. thick each. The concussion of heavy shot striking them occasionally drives the nuts off the bolts which bind the plates together, killing or wounding those within the turret as effectually as so much shot. The 15-in. guns are mounted on a heavy wooden carriage, much like the old-fashioned 68-pounder carriage used in our Navy. The wheels run on a kind of railroad, mounted on two powerful balks of timber, which cross the turret diametrically, or nearly so. The forward pair of wheels are fitted with gearing, and the gun is run out, or rather forward, by a couple of men putting this in motion by suitable winch handles. The port is rather high, but only 16 in. wide, so that the muzzle of the gun does not at any time protrude, but is run right up, in firm contact with the inside of the turret wall. Aim is taken by causing the turret to revolve. An iron box, rectangular in section, and about 3 ft. long, contains the muzzle of the gun when run forward. This prevents noise, and preserves the men from

concussion. Between the sleepers on which the gun travels are bolted several longitudinal timbers, side by side. From the under part of the carriage a number of long plates of boiler iron depend, passing between the timbers. A powerful screw, worked by a hand-wheel at the side of the carriage, is arranged to compress these plates on the timbers to any extent deemed necessary. The friction produced is so great, that the recoil of the gun permits of exact regulation, being easily arrested in 4 ft. The guns are invariably of cast iron, reinforced with a single wrought-iron hoop.

All things considered, the introduction of ordnance of this size into our military or naval operations does not seem advisable, the Parrott 10-in. gun being superior in every respect. A 200-pounder shot, moving with a high initial velocity, is capable of smashing any iron plate at short range which can ever be fitted to a ship's side, and the weight of both the gun and the shot is fully as much as we can manage at sea under existing arrangements.

PERMANENT WAY.

Many thousands of pounds are annually wasted in the destruction of permanent way. We do not mean in legitimate wear and tear, but in that unnecessary deterioration which results from the employment of bad materials, the use of needlessly heavy rolling stock, and a faulty system of construction. Our railways date back some thirty years only; the first ten of these we may regard as having been devoted to experiment, from which certain rules were deduced to which our railway companies have adhered ever since, regarding apparently, further improvement as either unnecessary or unattainable. Economy has been sought for in the use of cheap rails, cheap sleepers, cheap chairs, &c., rather than in the adoption of those which, dearer at first, would, by their superior durability, effect a continuous annual saving in the outlay for maintenance. Indeed, this plan was carried to such an extent a very few years ago, that rails were little better than cast iron, being supplied at contract prices which effectually precluded their proper manufacture. Such rails have been known to break in two by being thrown from a waggon to the ground; while their duration, even when laid with great care, properly attended to, and nursed through their trials, rarely exceeded twelve months. This mode of proceeding was soon discovered to be simply ruinous; and a better class of rail, made almost without regard to expense, from good iron, properly piled and faggoted according to specification, is gradually finding its way into general use, with the best results. The first cost of a track laid with good bars is really very little greater than one laid with those of inferior quality, a much smaller quantity of iron sufficing per mile of road; a 45 lb. rail, if good, being fully equal in every respect to one of 60 lb., if bad.

A theoretically perfect track should be composed of rails absolutely hard on their wearing surfaces at least, incapable of deflection, and so laid that subsidence in any way, would be a mathematical impossibility. So long as we consider the permanent way alone without reference to the rolling stock, no difficulty presents itself to the carrying out of these conditions with an extreme degree of accuracy. Heavy rails, very deep, and steeled on the tables, keyed or bolted into large chairs, bedded on solid blocks of stone, carefully rammed and ballasted, would supply just such a track. But the conditions under which engines and vehicles can alone proceed with success, introduce the element of elasticity, which stone blocks and heavy rails do not supply. And in the reconciliation of these contending points lies the real difficulty of the question. If we retain the stone blocks; wood, felt, or india-rubber cushions must be introduced, either between the stone sleepers and the chairs, or between these last and the under surface of the rail. These cushions, in order to discharge their functions, must permit some play in the rail; and this once begun, cannot, by any arrangement yet adopted, be restrained within legitimate limits. Hence a very short time suffices to destroy the elasticity of the cushions. The spring of the system is then converted into jar and concussion, and the rapid destruction of the whole follows as a matter of course. Every plan which has been hitherto proposed for fixing rails to rigid sleepers has failed, and, in consequence, the employment of those which possess enough elasticity to prevent the necessity for separate springs, is all but universal. Timber has thus become as necessary for the formation of the substructure of a line of railroad, as iron for the superstructure; and the selection, preservation, and deposition of this rather perishable material becomes a matter of primary importance.

Considered in the abstract, however, wood is anything but a good substitute for stone, its first cost and rapid decay rendering it very objectionable. Whatever system is adopted, when flat-footed rails rest directly on timber sleepers, they sooner or later sink into them by crushing the fibres. The holding-down bolts, screwed up tightly at first, soon become too long in consequence; and the rail, no longer kept in firm contact with the wood, springs up and down on the passage of every train, acting to some extent as a hammer on the already weakened fibres, which absorb water like a sponge. The under surface is scarcely better off. Seldom or never packed up equally, hollows form between the wood and the ballast, which becomes hardened by the temporary pressure of the sleeper when deflected by superincumbent weight. Water collects in these hollows, and the wood rots from its effects. The crushing of the fibres is aggravated by the longitudinal system, to such an extent, that thin cross-boarding between the sleeper and the rail-foot has been used with considerable advantage; but this introduces an item of expense, and is, after all, but a sorry expedient. In the absence of chairs, it is better in all cases to place the sleepers across the track. A tolerably good line may be made in this way on good ballasting. The Great Southern and Western of Ireland is laid with 92 lb. rails, on this system, without fishes. The Chemin de Fer du Nord has several hundred miles laid with 74 lb. rails—carefully fished however—in the same way. Both these lines are worked by heavy engines—the Engerth Tank engines on the latter being, perhaps, the heaviest in the world, weighing 63 tons. Far more attention is paid to ballasting in France than here, the official report in 1857 showing that 17 per cent. of the whole cost of formation of the French railway had been for ballast. The cost of maintaining a cross-sleeper line laid with Ω rails will bear favourable comparison with almost any of the other systems; but it is seldom so easy on the rolling stock as it should be.

The double-headed rail, combined with cast-iron chairs, is so thoroughly habitual in Great Britain, that we need not dwell on the well-understood imperfections of a system with which our readers are familiar. Regard the matter as we will, we find the elastic sleeper arrangement defective, in that it entails the use of a destructible material, that it permits and indeed presupposes a considerable amount of deflection or yielding in the track without securing its proper elasticity, and that it is expensive both in first cost and maintenance. When rails sink under the tread of the wheels, they add materially to the expenditure of power required for the transport of a given load. In this, we find one reason why light locomotives do more work—especially on a weak road—proportionately, than those which are heavier; the deflection of the rail producing a resistance corresponding with the ascent of a continuous incline. All attempts at the use of a rigid substructure have, however, hitherto failed; and we are, to all appearance, as far from possessing anything like the theoretically perfect permanent way which we have described at the commencement of this article, as we were in the days of Stephenson the elder.

Now this is the case solely because we have for the last thirty years endeavoured to fit the rails to the carriages, instead of the carriages to the rails. We employ heavy vehicles, in the first instance, which so far injure the permanent way that it becomes unfit for those of lighter and perhaps weaker construction. Heavy carriages require heavy locomotives; and the permanent way is thus taxed to the utmost limit of endurance. Heavy rails are considered the only panaceæ, and expenses are increased without making the line really good. Starting with the conviction that elasticity between the wheel and the real support, the ballasting, is absolutely essential, it is not difficult to see that this may be as well attained by making the bearing of the wheel tyre elastic on the rim proper, as by making the bearing of the rail elastic on rigid supports; with this difference, that, whereas the latter is impossible from mechanical exigencies, the other is quite practicable. We must observe that no necessity exists for making the rail elastic, neither does there for making the tyre; it suffices that the rail rest on a spring cushion, and the same is true of the tyre. A case somewhat analogous may be found in the substitution of wheels for sledges. So long as the surfaces of rails are kept smooth and carefully lubricated, so long will a carriage mounted on runners travel along them with ease. These conditions are impossible of fulfilment, and the wheel becomes an expedient by which the friction is transferred from the surface of the rail, where smooth surfaces and efficient lubrication are not attainable, to the axle-box, where they are. Now, if the element of elasticity cannot be secured between the rail and its support, the stone sleeper, it remains to introduce it between the tyre and its support, the felloe of the wheel. The experiments conducted lately on the St. Helen's Railroad demonstrate the perfect practicability of such an arrangement; and it would be well worth while to try an engine suitably fitted, over a mile or so of road laid as rigidly as heavy rails and stone sleepers could secure. The outlay would not be much; and if successful—which we do not doubt—the experiment would be the harbinger of a revolution in railway practice which would lead, in the course of a few years, to a saving in the expenses of maintenance which would tell most favourably on dividends.

BOILER EXPLOSIONS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—I have recently seen leading articles in the *Engineer* and the Mechanics' Magazine successively, upon what has been called the theory of boiler explosions, but more properly the theory of the violence of boiler explosions, in which the origination of the "pro-

jectile theory" (first so-called by myself in the *Encyclopædia Britannica*, and recently adopted under the same name in the *Engineer* of the 5th instant), is attributed in exactly the same proportions to Mr. Colburn and myself; and therefore, of course, any communication from me on the subject may apply equally to both articles. Mr. Colburn, it may be supposed, is the editor of the *Engineer*, and is also the writer of the articles that have appeared in that paper on the subject of the projectile theory; and I should naturally have addressed these remarks to that paper, but for the undignified personalities in which the editor indulges, and for the still more serious offence of suppressing legitimate correspondence.

I am, therefore, in hopes you will allow me to refer Mr. Colburn and the editor of the *Engineer* to my two letters on the projectile theory, which appeared in the MECHANICS' MAGAZINE of the 3rd and 10th May, 1861, and also to your leading article on the subject printed at the same time, on the 10th May. In those letters I endeavoured carefully and exactly to trace the course of the discussion in the *Engineer*, and showed that Mr. Colburn had not contributed in any material degree to the maturing of the theory, of which the first notion was originated by Mr. Harshman, and published by him in a pamphlet in 1855, and afterwards by letters in the *Engineer* in 1859.

To those two letters from me neither Mr. Colburn nor the *Engineer* has yet made any reply. In a note addressed to me, Mr. Colburn has, in fact, acknowledged that I have given him "*nearly all he knew of the action of steam by momentum.*"

I would also remind you, Mr. Editor, that you, in your leading article of May 10th, 1861, assign to me the credit of the prior claim to what is new in the projectile theory, and that you invited Mr. Colburn to show what he could fairly claim in the matter with reference to my correspondence. This he has not yet attempted.

In conclusion, I may remark that when one of two parties to a discussion is the editor of the paper in which it is attempted to be conducted, it is obvious that the editor has the advantage of position. He has his back to the sun without tossing for it. I have in my possession a mass of correspondence with Mr. Colburn on the subject of the projectile theory, and I have frequently proposed to him, as he appeared to consider the discussion and the settlement of the question to be of great importance, to talk over and arrange the matter quietly in the presence of one or two witnesses, who would take notes, and correct subsequent errors of memory, and so terminate this one-sided controversy. The proposal was at first accepted, and subsequently declined by him. The projectile theory was started by me in the course of a conversation I had with Mr. Colburn and his friend, Mr. Holley, of New York, in my office, on the subject of the explosion of the feedwater heater on board the "Great Eastern" shortly after it happened, when I put to them the direct question: How did it happen that the external casing was burst at the same instant that the chimney collapsed? There were two distinct simultaneous failures, of exactly opposite characters. Now the point requiring explanation was this—that an outer shell, subject only to internal pressure, should fail by bursting, as soon as a flue of nearly the same diameter collapsed, seeing that internal pressure is so much more easily resisted by cylindrical vessels than external or collapsing pressures. Neither Mr. Colburn nor Mr. Holley made any reply; and I suggested that the external shell was burst by the steam and water rebounding from the collapsed flue, the sudden enlargement of volume by the collapse of the flue giving rise to a sudden evolution of steam amongst the water, and a sudden dispersion and projection of the water against the inner surface of the casing by the force of the steam. In the number of the *Engineer* following the conversation referred to, Mr. Colburn attempted to explain the explosion in very contradictory terms. But I am reluctant to go over again the ground which I have already traversed in my letters of May, 1861, in the MECHANICS' MAGAZINE, and now briefly revert to that subject, to recall the attention of those who are sufficiently interested in tracing up the history of the projectile theory to the explanations I then made. I submit that the publication of matter in a journal, though one mode of establishing priority of claim, is not the only mode; and I propose to refer the whole question to a competent judge of evidence—say Queen's Counsel, and to accept his decision.—Your obedient servant,

D. K. CLARK.

11, Adam-street, Adelphi, London.
September 22, 1863.

[We are pleased to find that Mr. Clark does not substantially contradict any statement we have lately made with regard to his claim to the origination of the received theory of explosions. Mr. Colburn was the first to *publish* his views of the matter, and it is quite beyond our province to pronounce on their originality. We cannot, in our editorial capacity, recognize any private conversation or unpublished letters as evidence bearing on the case. Mr. Clark may probably have communicated his ideas to many others as well as to Mr. Colburn; but with that we have nothing to do, as we can only interfere in the question of priority of publication. We must beg to differ from Mr. Clark in our estimate of the value of Harshman's theory, which really bears very little relation to the one under consideration. And we have already expressed an opinion on the projectile theory, which shows that we are not prepared to fully endorse it in its present form. —ED. M. M.]

GREEK FIRE.

JUDGING from the outcry which has been raised against General Gilmore by certain partizans of the "so-called Confederate States" for the use of shells which contained "Greek fire," one would think that nothing had been done in this country to patent and perfect such instruments of destruction. It so happens, however, that the Americans are only following our teachings in this particular. Readers of the MECHANICS' MAGAZINE have, for years past, been made familiar with inventions having for their object instantaneous and unmitigated destruction. We do not know of what "Greek fire" is composed, neither do we know the origin of the phraseology. From certain obscure documents of the Eastern Empire, we suppose the designation "Greek fire" means either a rocket, or a liquid combustible material, composition unknown, which, being projected through tubes or in jars, set fire to combustible substances. During the Russian war, Capt. Disney exhibited at a public meeting certain glass shells, which, when thrown against a hard substance, burst, and, in a few seconds, set fire to all combustible material with which they came in contact. Before this, Capt. Norton had suggested a small-arm incendiary rifle projectile. At one time, scarcely a month passed without a little letter appearing in our columns from the last-named gentleman describing some "Beelzebub" machine, which had for its object rapid and certain destruction in war. During the Crimean war, Mr. J. Macintosh called the attention of the Government to the extraordinary efficacy of certain projectiles, which he called "liquid-fire" shells, and to the application of other fiery materials in warfare. A special committee was appointed to inquire into the whole question, and a series of experiments was tried at Shoeburyness, by which inflammable materials were consumed at a distance of 800 yards. In August, 1855, Mr. Macintosh patented another invention. The following passage occurs in the specification:—

"I fill diaphragm shells with coal-tar naphtha, mixed with phosphorous and bisulphuret of carbon, having a bursting charge sufficient to open the shells. When fired, the bursting of these shells scatters the contents in all directions, and the shower of inflammable material, falling among cavalry and troops, ignites spontaneously, causing their immediate disorganization. Fired into shipping, these shells, bursting on deck or below, scatter the inflammable material in all directions, and the spontaneous combustion which arises causes inevitable and irremediable injuries and destruction to the crew, who are unable to escape except by dropping overboard, and the vessel itself is speedily consumed, aid from the crew having been rendered impossible as just described. Fired into harbours, dockyards, or towns, the result is alike destructive and decisive."

The use of such shells may be denounced as inhuman and contrary to the usages of civilized warfare. Is not all warfare uncivilized and barbarous? No doubt the invention of gunpowder and its application to warfare was at one time considered inhuman, as the application of liquid fire is considered by some now. If, however, men will go to war, the more deadly and destructive the modes of warfare are made the better. In the earlier ages victory was generally given to the army which could march the quickest and endure the most. Then, *brute* force was the arbiter in quarrels; now, *science* has superseded brute force. Victory waits, in these days, on intelligence and invention, and not on strength of muscle. Though the "so-called Confederates," as Earl Russell terms them, have exhibited a vast amount of bravery and endurance, they are not as yet a match for the Federals in the "*art* of war." Such a result, in fact, might have been expected. The Southern States have produced a host of orators and able statesmen; the Northern States have been most prolific in invention and scientific discovery. In fact, almost everything done in America in scientific research and improvement has come from the North. The Northerners are masters of the situation, not only on account of their great resources, their superior numbers, and their better cause, but because they are enabled to evoke more assistance from science than their enemies. We have consumed years and millions sterling in endeavours to perfect a system of Armstrong artillery, and are not advanced, according to the report of the last Commission of Inquiry, beyond the old 68-pounder; whereas the Federals, in a few months, have literally done wonders. English artillerists are startled at the results which have been achieved. The Federals have thrown explosive projectiles 15 in. in diameter, seven miles. The south should have calculated on the superior scientific facilities of the North before they submitted their case to the uncertain and bloody arbitrament of battle; and English journalists and caricaturists, now they see the matchless energies and scientific resources of the North, will perhaps moderate their temper and deal less fluently in insulting epithets. They will, at all events, no longer repeat the silly expression of an English clergyman, that Yankeys are as much inferior to Englishmen as monkeys are to men. Peradventure, even reckless shipbuilders, who, in their greed

of gain, have brought, as the *Times* said on Wednesday last, this country "to the verge of war," will, at the eleventh hour, and in obedience to necessity, listen to the voice of conscience which a great tribune a short time since so eloquently evoked.

Though the North has beaten the South in construction of guns, the South has mastered the North in the manufacture of torpedoes. Our last number contained a description of these "inventions of the devil," as they were called, which have been so liberally distributed in the Missisippi river and Charleston harbour. One morning a torpedo exploded near the "Pawnee," and blew her launch to fragments; a few moments after another exploded, and then another. These machines are constructed with remarkable ingenuity. As they float down the tide the anchor-chain of the vessel which is to be destroyed, catches the ropes which attach the torpedoes; the torpedoes then swing round and strike the sides of the vessel. It so happens, however, that these machines are no respector of persons. When floating on the tide, they are as ready to sink the enemy's gunboat as to shatter to fragments vessels laden with friendly assistance which may have run the blockade.

Captain Maury, who is by far the most scientific man the Southern States have produced, has just written a long letter to the *Times*, soliciting British sympathy on the ground of the inhumanities committed by Northern armies. He omitted to state that Southerners commenced, through Morgan and others, destructive raids on inoffensive districts; and that the "Alabama" and "Florida" pitilessly destroy what they cannot appropriate on the high seas. He omitted to state that these vessels burn the ships they capture at night-time so that they may attract other ships to the scene of conflagration, to meet a similar doom. We would advise Captain Maury to read Emerson's Essay on "Compensation." Whatsoever men sow, that shall they reap. The Southerners have sown the wind, and are deservedly reaping the whirlwind.

J. P. E.

THE "BARON OSY" STEAMER.

HAVING, in bygone times, enjoyed several trips on this fine steamer, our interest in the vessel led us to pay her a visit of inspection, during her present unfortunate plight. It will probably be known to most of our readers that the "Baron Osy" steamer (built by Mr. Scott Russell at Millwall) was lately sunk in the river—while coming up Limehouse Reach on her way from Antwerp to St. Katherine's Wharf—nearly opposite Mill Stairs. She is supposed to have struck on some lost anchor or mooring ring. Whatever the thing was, it stove in her bottom, and dragged a rent more than 9 ft. long. As she was making water very fast, her stem was turned to the Surrey shore; her bow sank with the rise of the tide, but being provided with a water-tight bulkhead, her after-part only sank in about 15 hours. She had nearly 100 passengers, and a cargo of 9 boxes of bullion underneath a cwt. of baskets of walnuts, which had to be hastily thrown up from the after-hold in order to save the gold.

The work of raising the vessel—safely accomplished on Saturday fornight—presented a striking scene. At low water, chains, pinned to lighters, were passed under her bottom; ropes being laid to haul the vessel to shore as she lifted. Two powerful steam pumps were placed on board, one over the after, and the other over the fore hatch; in the first case, a 9-in. delivery centrifugal pump (by Clinton and Owens), driven by an 8-horse portable engine; in the second, a pair of the Norton V-pumps, now attracting so much attention from the admirable simplicity and ingenuity of their construction.

The leak is in the fore part of the vessel, separated from the after part by a water-tight bulkhead, and accordingly Norton's pumps were placed over the fore hatchway—the post of hard work and of honour. These pumps drove quite a cataract of water over the side of the vessel. They reduced the depth of water at the rate of 2 in. per minute, and in less than 35 minutes 5 ft. of water were pumped out of an area of about 51 ft. by 22 ft. The vessel then rose on the early flood, and was safely got over to the Surrey side of the river.

The performances of these pumps so much attracted our notice that we have ascertained their exact dimensions and performances for the benefit of our readers. In our number for last April, page 308, will be found an illustrated account of this remarkable description of pump, so that we need not here enlarge upon its mode of construction. The particular pumps in question, were fitted with 8-inch V's, 12-inch stroke, and a 10-inch suction pipe. They were driven by a 6-horse power engine, making 70 revolutions per minute. The boiler worked with 35 lbs. pressure of steam, consuming 84 lbs. of coal per hour. The water was raised at the rate of 65,000 gallons per hour, weighing, of course, 260 tons. It must be also remembered that the river was pouring in at a leak from 9 ft. to 10 ft. long, and in some parts nearly 3 in. wide. Altogether, the owners of this new pump may well be proud of its last feat.

We understand that the "Baron Osy" will have to be docked in order to repair her great damages; and after being purified of the odoriferous Thames mud by means of fire-engines, this fine vessel will, no doubt, be again placed on the London and Antwerp line.

THE "PRINCE CONSORT."

THE "Prince Consort" was laid down at Pembroke as a line-of-battle ship on the same lines as the "Gibraltar"; but was afterwards cut in two, lengthened 23 ft., and, like the "Ocean," reduced to a two-decker. She was first called the "Triumph," but this name was altered to the "Prince Consort." Her launch took place in June, 1862. The dimensions are:—Length over all, 277 ft.; length between perpendiculars, 273ft.; keel for tonnage, 232ft. 3¾in.; breadth extreme, 58 ft. 5 in.; ditto for tonnage, 57 ft. 2 in.; ditto moulded, 56 ft 4 in.; depth of hold, 19 ft. 10 in.; tonnage, 4,045 26-94 tons; ditto Board of Trade 3,521·34 tons; tonnage of engine-room, 1,913·74 tons; ditto register, 1,907·6 tons; displacement when light, 2,924 tons; ditto estimated when loaded 6,328 tons; estimated draught when loaded, 23 ft. 7 in. forward, 25 ft. 2 in. aft. Her draught when launched, was 12 ft. 11 in. forward, and 16 ft. 10 in. aft.; mean draught, 14 ft. 10½ in. It is intended on her trial trip, which will shortly take place, to make her draw 23 ft. 8 in. forward, and 25 ft. 8 in. aft. Her iron masts are stepped, and the guns are on board; there will also be six months' stores in her; the remainder will be made up with iron ballast. The heel of the main mast is forked to admit the propeller shaft; the mast is 115 ft. 6 in. long; foremast, 109 ft. 6 in.; mizen, 82 ft. 8 in., and bowsprit, 41 ft. 6 in., all of iron. The armament on the main deck is 24 guns for 8-in. solid shot, each weighing 25 cwt., with four Armstrongs, 110-pounders, each weighing 84 cwt. forward, and the like number aft.; on the upper deck two Armstrongs forward and one aft, 45 in all. The engines collectively of 1,000-horse power (nominal) are from the manufactory of Messrs. Maudslay, Sons, and Field, and are seated 15 ft. before the mainmast; they are termed "horizontal double piston rod." The horizontal double action air-pump is worked direct from the engine. Each of the engines is fitted with box slides; worked by double eccentric and link motion. The air-pump valves are of india rubber, with metallic valves to discharge through the sides of the ship. The air-pumps are 29 in. in diameter, and have a 4 ft. stroke. The inside diameter of the steam cylinders is 92 in.; they are steam jacketed. The diameter of the main steam pipes is 23 in. There are also in the engine-room two small auxiliary engines of 12 in. diameter. Each of these is fitted with a pump for filling boilers from the sea, together they are capable of supplying the requisite amount of water when the main engines are working full boiler power. She has in addition a double 7 in. pump, which can be worked by hand or steam, capable of supplying a sufficient quantity of water for working half-boiler power, and arranged so as to pump on deck or overboard and to draw water from the bilges or the sea. The "Prince Consort" has two stoke-holes—the one before the engine-room has four boilers, with five furnaces in each; the one, abaft four boilers, with furnaces in each. The eight boilers contain 3,840 tubes, each of which is 6 ft. long by 2½ in, outer diameter, and 2¼ inner diameter. By the forward boilers the power of 600 horses (nominal) can be obtained, and by the other 400 horses, calculated at 7 lb. effective pressure per square inch. The fore chimney is 8 ft. 3 in. diameter, the after 6 ft. 6 in. Both stoke-holes are well ventilated; but the presence of the screw shaft casing, shoulder high, in the after stoke-hole, is very inconvenient. The after stoke-hole is, however, a little wider than the fore stoke-hole. The length of the propeller shaft inboard is 98 ft. 3 in., weight 17 tons, diameter 18 in. forward, and 20 in. aft. The gun-metal screw-propeller is four-bladed; it weighs about 15½ tons, and overhangs, or, rather, has no outer bearing. The diameter is 21 ft., and the pitch on Maudslay's principle, can be altered from 20 ft. to 25 ft. The stern bracket is surfaced up, and the boss of the screw is surfaced also; the machinery is arranged so that the screw-shaft can be carried forward to close the opening entirely when the two surfaces meet, and thus the sudden influx of the sea can be prevented in case of an accident similar to that of the "Royal Albert" in 1856, when the water rose to her ash-pans, and her commander was obliged to run her on a sand bank in the Island of Teo, in the Mediterranean. The "Prince Consort's" screw shaft is fitted with a disconnecting clutch and friction brake, by which, when the ship is under canvas only, the screw will be allowed to revolve freely in the water. The brake can be used when necessary to stop the screw, and reconnect it with the engines for the purpose of resorting to steam. In the fore stoke-hole there is a spare blade for use in case of accident; like the others, its flange is perforated with slotted holes for the reception of the screws which fasten it to the boss. The blades are twisted slightly, and become much thinned towards the outer ends. The engines and machinery weigh 750 tons; the cost is about £50,500, and the manufacturer obtains in addition £1 per horse power (£1,000) for placing them on board. To aid the ventilation, holes have been peforated in the masts above and below, and the coal shoots have hollow-work deck covers, which admit both air and light. Cowl-head ventilators can be substituted. On the suggestion of Mr. Sampson, her engineer, her iron flaps in the air casings which inclose her smoke chimneys below give place to glass doors, by which light as well as air is admitted to the 'tween decks. At each side of the upper deck of the "Prince Consort," amidships, there is a round tower, 7 ft. high and about 5 ft. diameter, constructed of wood 12 in. thick, which will be plated with iron 4 in. thick. The shipwrights' work is complete, and, excepting the last coat, which will not be applied until she is further advanced, most of the painters' work is finished. The "Prince Consort," though not built for, can be used as a ram; she is classed with the "Caledonia," built at Woolwich; the "Ocean," at Plymouth; the "Royal Oak," at Chatham; and the "Royal Alfred," at Portsmouth. The two last have engines of 800-horse power, the other three of 1,000-horse. All are iron-plated. The number of plates on the "Prince Consort" is 259, and weight 873 tons; bolts and nuts, 26 tons; those on the "Ocean" will be 275, weighing 935 tons; the odd plates go round the stern. The plates on the "Prince Consort" are rolled; those on the "Royal Oak" are hammered. Where the displacement of the "Prince Consort" is 6,328 tons, that of the "Royal Oak" is over 7,000 tons.—*Times*.

IMPREGNABLE SHIPS OF WAR.

MR. W. W. WARREN proposes to construct ships-of-war which shall be impregnable, and capable of discharging their guns under the water level.

"I prefer," writes Mr. Warren, "constructing the centre portion of the vessel of rolled wrought-iron double-flanged vertical ribs, from 12 to 18 in. wide, and from 2 to 4 in. thick, firmly rivetted and bolted together, or of angle or T iron, solidity and stiffness being the great object, on which are placed the various layers of malleable metals, taking care to stop all chemical or galvanic action, by means of bituminous composition mixed with hair; and were it not for the cost I would prefer using the finest copper-plating only over the iron, so as to act on the principle of a gradual tenacity of resistance, thereby easing and stopping the momentum, and distributing the shock, and thus prepare the iron-plating to firmly resist, without splitting or destroying the plate; or

the roof-deck and sides of centre position of battery can be protected with oak, or other wood, compressed in short lengths, and confined, the cross-grain of wood being opposed to the action of fire.

"The fore-and-aft and other portions of the battery, not requiring armour-plating, to be constructed with wrought-iron ribs, with an outer skin only, and to be filled in with hexangular or honeycomb compartments of the maximum size of shot, made in short lengths, and firmly rivetted and bolted together, so that, in case of water entering, it is confined to the track of the ball, after which it can be easily stopped, and by an arrangement of valves can be pumped out. To wooden-ships, if armour-plated at all, I would apply the plating inside thereof, thereby making the external wood act as a buffer or padding. The port-hole for discharging the submarine gun must be provided with water-tight metal flap, instantly closing after the recoil of gun, the barrel of gun acting in a stuffing-box, with a water-tight box adjoining for adjusting cap to muzzle. The port-hole to be provided with a slide valve, as an extra precaution. The cap can be made of any reasonable length, so as to displace a greater volume of water, and, if necessary, a telescope tube can be adjusted to port-hole and elongated by a rack-and-pinion movement, or an ordinary muzzle-loading gun can be used, by simply applying a waterproof flexible hose, of sufficient length to allow of the recoil of gun, and having moveable collars attached to muzzle and port-hole. The hexangular cellular system is not only capable of displacing and carrying any weight of armour-plating, but is admirably adapted for the reconstruction of existing wooden ships, thereby making them seaworthy and unsinkable at a comparatively small expense, without the necessity of armour-plating at all, simply by placing the hatchways to lower deck; and is likewise admirably adapted for the construction of life-boats, floating docks, &c., on account of it reducing the maximum amount of external injury to the minimum amount of internal damage."

Mr. Warren's principle of construction seems to be good; and, in the absence of experiment, it would be premature to pronounce an opinion on the probable success with which guns could be discharged under water.

ON SPECTRAL ANALYSIS.*

By Prof. PLUCKER.

IT is generally admitted now, that every gaseous body rendered luminous by heat or electricity sends out a peculiar light, which, if examined by the prism, gives a well-defined and characteristic spectrum. By such a spectrum, by any one of its brilliant lines whose position has been measured, you may recognize the examined gas. This way of proceeding constitutes what is called spectral analysis, to which we owe, until this day, the discovery of three new elementary bodies. In order to give to spectral analysis a true and certain basis, you want the spectrum of each elementary substance. Most recently, some eminent philosophers, in examining such spectra, met with unexpected difficulties, and doubts arose in their minds against the new doctrine. These doubts are unfounded. The fact is, that the molecular constitution of gases is much more complicated than it has been generally admitted till now. The spectra, therefore, always indicating the molecular constitution of gases, ought to be more complicated also than it was thought at first. By these considerations, a new importance, a rather physical one, is given to spectral analysis. You may recognize, by the spectrum of a gas, not only the chemical nature of the gas, but you may also obtain indications of its more intimate molecular structure—quite a new branch of science. Allow me now to select out of the results already obtained two instances only. Let me try to give what I may call the history of the spectra of two elementary bodies—of sulphur and nitrogen. In order to analyze by the prism the beautiful light produced by the electric current, if it pass through a rarified gas, I gave to the tube in which the gas is included such a form that its middle part was capillary. Thus I got within this part of the tube a brilliant film of light, extremely fitted to be examined by the prism. The date of my first Paper on this subject is the 12th of March, 1858. After having provided myself with apparatus more suited to my purposes, I asked, about a year ago, my friend, Prof. Hittorf, of Münster, to join me in taking up my former researches. The very first results we obtained in operating on gases of a greater density opened to us an immense field of new investigation. We found that the very same elementary substance may have two, even three, absolutely different spectra, which only depend on temperature. In our experiments we made use of Ruhmkorff's induction coil, whose discharge was sent through our spectral tubes. In order to increase at other times the heating power of the discharge, we made use of a Leyden jar. Now, let us suppose a spectral tube, most highly exhausted by Geissler's mercury pump, contains a very small quantity of sulphur. The discharge of the coil will not pass through the tube if it do not meet with ponderable matter, either taken from the surface of the glass, or, if the discharge be very strong, by the chemical decomposition of the glass. In heating slowly the tube by means of a lamp, in order to transform a part of the sulphur into vapour, all accidental spectrum, if there be one, will disappear, and you will get a pure and beautiful spectrum of sulphur. I supposed the Leyden jar not to have been interposed. If you now interpose it, the spectrum just spoken of will suddenly be replaced by a quite different one. We were generally led to distinguish two quite different classes of spectra. Spectra of the first class consist in a certain number of bands, variously shadowed by dark traversal lines. Spectra of the second class consist in a great number of most brilliant lines on a dark ground. Accordingly, sulphur has one spectrum of the first class and another one of the second class. You may as often as you like obtain each of these two spectra. In operating on a spectral tube, containing nitrogen at a tension of about 50 millimètres, you will, without the Leyden jar, get a most beautiful spectrum of the first class. After interposing the jar, a splendid spectrum of the second class will be seen. But here the case is more complicated yet. The above-mentioned spectrum of the first class is not a simple one, but it is produced by the superposition of two spectra of the same class. Ignited nitrogen, at the lowest temperature, has a most beautiful colour of gold. When its temperature rises, its colour suddenly changes into blue. In the first case, the corresponding spectrum is formed by the less refracted bands extended towards the violet part; in the second case, it is formed by the more refracted band of the painting extended towards the red. Nitrogen, therefore, has two spectra of the first class, and one spectrum of the second class. The final conclusion, therefore, is that sulphur has two, nitrogen three, different allotropic states. It may appear very strange that a gaseous body may have different allotropic states—*i.e.*, different states of molecular equilibrium. It may not appear, perhaps, more strange that a substance, hitherto supposed to be an elementary one, may really be decomposed at an extremely high temperature. From spectral analysis there cannot be taken any objection that sulphur and nitrogen may be decomposed. Chloride of zinc (or cadmium), for instance, exhibits two different spectra. If heated like sulphur, and then ignited by the discharge of Ruhmkorff's coil, you will get a beautiful spectrum either of chlorine or of the metal, if either the Leyden jar be not interposed or be interposed. There is, in this case, a dissociation of the elements of the composed body in the highest temperature, and re-composition again at a lower temperature. You may consider the dissociation as an allotropic state, and, therefore, I may make use of this term as long as the decomposition be not proved by the separated elements.

ON THE SYSTEM OF FORECASTING THE WEATHER PURSUED IN HOLLAND.*

By Dr. BUYS BALLOT.

THE author said:—"I shall not abuse your indulgence, which I earnestly implore. I shall very shortly explain (1.) what are the rules about foretelling weather in Holland, given before a similar system was introduced in England; (2.) how they behaved themselves; and (3.) what is to be done now; and I will very abundantly answer to any question or remark if they be made, for in that case I am justified in trespassing on your time.—(1.) Under our plan, where observations are taken in Holland, there are four principal places: Helder indicated by H, Groningen indicated by G, Flushing indicated by V, and Maestricht indicated by M, on the indications of which I base my forecasts, and in the first place on the barometer readings. For every day of the year and for every hour of the day I have very carefully determined the height of the barometer in the place of observation at that height above the sea, where it is suspended. This is a cardinal point not sufficiently observed in England, and not at all in France. The difference of an observed pressure from that calculated on I call the departure of the pressure—positive when the pressure is greater, negative when it is less. Those departures, besides the observations of the other instruments, are communicated from post to post. The rule is now very simple. If the departures are greater (more positive) in the southern places than in the northern, greater at M or V than at G or H, the wind will have a W. in its name; when the departures are greater in the northern places the wind will have an E. in its name. More accurately you may say, The wind will be nearly at right angles with the direction of the greatest difference of pressures. When you place yourself in the direction of the wind (or in the direction of the electric current) you will have at your left the least atmospheric pressure (or the north pole of the magnet). When the difference of pressure of the southern places above the northern is not above four millimètres there will be no wind of a force above 30 lb. on the square mètre. Moreover, the greatest amount of rain will fall when the departures are negative; and at the places where the departures are most negative, there also the force of the wind will be generally stronger. Moreover, there will be no thunder if the barometric pressure is not less than two millimètres above the average height, and when at the same time the difference of the departures of temperature is considerable. Those rules, and especially the first two, were laid down by me, in 1857, in the *Comptes Rendus*, and on the 1st of June, 1860, the first telegraphic warning by order of the Department of the Interior was given in Holland. It was unfortunate that those telegraphic warnings were not introduced four days sooner, for in that case the first communication would have been a first warning against the fearful storm of May 28, 1860, called the Finster-storm. All of you know how amply Admiral FitzRoy has arranged the telegraphic warnings all over England.—(2.) Those rules used in Holland have behaved themselves very well, as is laid down in the translation of a Paper of Mr. Klein, captain of a merchant ship, whereto I have added my observations and signals compared with the signals of Admiral FitzRoy in table A, p. 25. My own Paper dates from June 1, 1860, and is extracted by Mr. Klein as you may see, but I preferred that the less complete and precise Paper of a practical man be translated, because I thought that the seamen would put more reliance on it. From the tables added to that translation it appears that I have warned from my four stations, just as Admiral FtizRoy has done from his twenty. It must, however, be recorded that, besides those four stations, there are also some stations—Paris, Havre, Brest—in France, and some in England—Hartlepool, Yarmouth, Portsmouth, Plymouth—that send me their observations. Generally they arrive too late, and, therefore, they throw but very little light on the forecasting, principally while the barometers are not so well known. So much for the strength, now for the direction. The direction is in the first twenty-four hours after the observations, three times of the four such as indicated, and the second twenty-four hours and the third twenty-four hours still two times of the three such as indicated (see table B, p. 29), and, moreover, no storm has occurred in those six years when not before the the difference of the southern departures above northern has been four millimètres.—To come to the third point. (3.) What is to be done? The normal heights of barometric pressure, or better of the barometers, which are read, must be conscientiously taken, the observation must be made at more points once a day, and mutually communicated, and at days when there are greatly different departures, that is to say, of three millimètres, or when there is a change of inclination, there must be sent a message at noon or in the evening of the same day. In all cases, not only the pressure in the morning, but likewise at night, should be given. A critical indication is, when the previous day the northern stations had greater departures and the following day the southern had greater departures, even when the difference in the latter case was small. There is caution to be had when the difference of the departures is four millimètres. But I may not trespass on your time and kindness in expressing wishes only, it may be sufficient to have communicated the general rule."

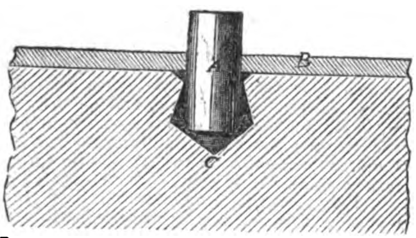
HASELTINE'S IMPROVEMENTS IN UNITING METALLIC SURFACES.

The following improvements in fixing sheathing on ships has been patented by Mr. G. Haseltine, of Southampton-buildings, Chancery-lane:—

This invention chiefly consists in securely joining thin metallic sheathing to iron plates by means of simple rivets, cut in suitable lengths from copper or other wire, and, for preventing galvanic action between the sheathing and plates, by the introduction of india rubber or gutta percha between the sheathing and said plates, either in the form of thin sheets, or by one or more coats of paint or wash, composed of said material, or of other substances possessing similar properties. These rivets, made to completely fill the perforations in the sheathing, pass into interiorly enlarged cavities formed for their reception in the metal plates. After their insertion into these cavities, the rivets are secured by blows struck upon the outer ends, which cause them to spread sufficiently at their inner ends to completely fill the cavities in the plates. A countersink is made in the plate at the mouth of each cavity, into which the edges of the sheathing is forced by the blows, which form at the same time the head of the rivet. By this means the sheathing is securely fastened to the plates, the heads forming with the sheathing a smooth and uniform exterior surface, as shown in the accompanying drawing.



In applying the above mode of uniting metallic surfaces to vessels plated with iron armour in which the joints between the plates are covered by strips of iron, the patentee inserts between the iron strips wooden strips of equal thickness to secure a uniform exterior surface to the hull of the vessel. These wooden strips render the process of sheathing the hull more convenient and less expensive.

LEBLANC'S WATER GAUGE,

Patented by Desire François Leblanc, 3, Percy-street, Bedford-square.

We feel much pleasure in laying before our readers particulars of a glass water gauge which is extensively used in France, and deserves general introduction here. It is not only stronger and safer perhaps than any other gauge which shows the water level through a transparent medium, but it possesses the great advantage of always denoting the presence or absence of water from the glass tube. The ordinary gauge may be quite full yet appear empty, or quite empty and appear full. It is impossible that such a result can take place with Leblanc's gauge, for reasons which the specification will best explain:—

Let us consider a rather thick-sided glass tube half-filled with water, we shall readily note the wide difference in refraction which exists between the full portion of it and the empty part thereof; and now let there be a screen provided with a circular hole of about two-thirds of the outside diameter of this tube placed behind that portion of it which is full of water, and this circular hole will appear in the form of an ellipse, having its great or transverse axis perpendicular to the axis of the tube, whilst on the same screen being removed behind the empty portion of the tube the ellipse assumes a rather lengthened form, having then its great or transverse axis parallel to that of the tube.

It follows from this, first, that such a screen may be used to inform us—when no solution of continuity appears in the tube—whether this is quite empty or quite full.

And secondly, that, however darkened its sides may be, unless they are altogether opaque, it will always be possible for any one to ascertain with its aid the presence or the absence of the liquid inside.

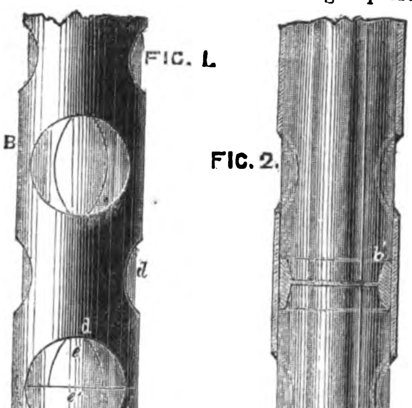
A metallic tube pierced from end to end with circular holes opposite to each other on two or three alternate diameters, and encasing the glass tube, may therefore become at once both a protection against breakages and their effects, and a means of more distinctly showing the height of the liquid inside.

Such is the nature and object of the said invention for "A Dioptical Metallic, Level Indicator or Liquid Gauge," but essentially consisting in the application of the combined dioptical properties of glass and water to the construction of a liquid gauge that should possess such requisites to clearness of indication and security of service as have never been as yet attained, it is susceptible of any form; for example, a glass tube consisting of several short ones may be advantageously substituted for that of one piece, and lenses for either of them.

Again, a casing made of any flexible mâtter, as vulcanized or hardened india rubber, or simply sheets of paper or cloth, impregnated with siccative greasy substances, rolled several times and stuck on the glass tube, may also be used instead of the metallic casing.

Being given a quadrangular opaque tube, the sides of which are pierced with two circular holes opposite to each other; if you fix in each of them a plano-concave lens, whose concavity faces the axis of the tube, and whose focus lies a little behind the opposite side; the hole that faces the lens which is looked at will appear greatly reduced in diameter, the tube being empty; whilst, on the same being filled with water, the index of refraction of this being pretty nearly the same as that of glass, the concavity of the lens is found to be almost annulled by the convexity of the water, and the opposite hole reappears with its nearly full diameter. The crown glass gives the maximum of differential effect.

Figs. 1 and 2 of the annexed drawings represent



a glass tube enveloped in a metallic casing pierced with circular holes opposite to each other. The metallic casing may be simply a non-adhesive case surrounding the glass tube, but it is better to have it fixed thereon, by means of a mastic or cement, such as that of ceruse and minium, oxychloride of zinc, and such like.

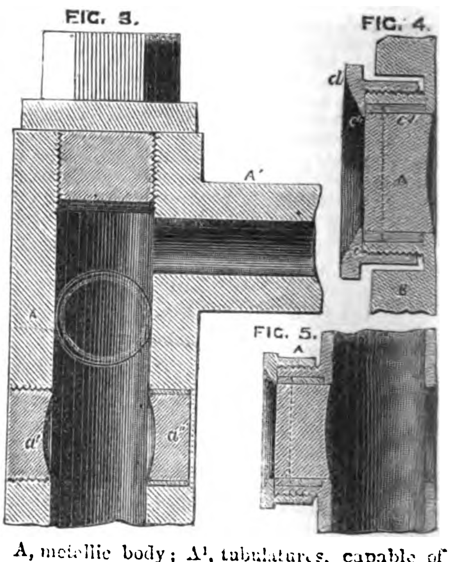
A is the glass tube; B, the metallic casing; c, the mastic; d, the holes of the casing; e, the outline and direction of the ellipse, as seen in the empty part of the tube; e^1, the same as seen in the part occupied by the liquid.

Indicators of unlimited length and best fitted to resist expansion will be obtained by using short glass tubes joined end to end. For this purpose it is necessary that each joint should correspond with the middle of a space without holes, so long as the sealing should prevent leakage.

The mastic of ceruse and minium, by reason of its solidifying slowly in a cold place, appears to be the most suitable one to employ. The complete solidification is obtained by its being exposed for two or three hours to a temperature of from 200 deg. to 250 deg. centigrade. All mastics that solidify slowly in a cold place and quickly in a hot one may likewise be advantageously used. Coloured mastics, and above all those coloured with black, render more distinct the perception of the optical phenomenon.

The glass tube extends a little beyond the metallic casing, in order to obtain a hermetical joint, in case the sealing of its extremities to its casing should not be quite water-tight, and thus to prevent acids and other agents from attacking the metal or the mastic. This disposition, however, is not indispensable, and in most cases the glass tube will be level with its casing.

Fig. 3 represents the section of an indicator, provided with lenses.



A, metallic body; A^1, tubulatures, capable of receiving cocks; a, a^1, a^{11}, plano-concave lenses. There are many means of fixing the lenses in the holes; they may be screwed with an oily mastic, as in a^1, or simply sealed with a mastic, specially that of cast iron in brimmed holes, as in a^{11}, or only hot fixed by means of a sufficiently fusible enamel, provided that the glass made use of be of a dilatation pretty nearly the same as that of the metal employed, which should be little dilatable itself, such as cast iron, iron, steel. I do not mention platinum because of its high price.

Lenses may also be placed on thinner tubes by means of tubulatures, A, fig. 4, into which they are fixed, either with a mastic or with india rubber, by means of a screw cap. They may likewise be sealed with an enamel into very thin tubulatures which will attenuate the effects of expansion. By enamelling the cast iron, iron, and steel tubes, they will thoroughly be kept from oxydation.

Fig. 5 represents an enlarged view of a mode of fixing the lenses in the tubulatures.

A, lens; B, side of the tube; c, externally screwed tubulature; c^1, matter of the joint, which matter may be, according to the case, either a ring of vulcanized india rubber, or amianth, impregnated with mastic, or simply oiled hemp for both low and mean pressures; c^{11}, metallic ring that compresses the joint; d, screwed cap, screwing on the metallic ring.

AMERICAN MEN OF WAR.

The "Dictator"—the large ocean "Monitor" at the Delamater Ironworks—is rapidly approaching a finished state. The *Scientific American* states that she will be launched some time during the autumn A strong force of men is at work, although they are not visible in masses, the vessel being so large that they are lost in her. The ship carpenters are busily engaged in putting on the timber backing of the side armour; it consists of oak logs, about 12 in. square, laid in sections; in all about 5 ft., as we are informed; outside of this there will be 10½ in. of iron, also put on in sections. The engines and turret machinery are well along, and progressing favourably.

The character of the engines is the same as those in all the "Monitors," with the exception that the cylinders and all reciprocating parts are vertical; a desirable feature in engines of this size—namely cylinders 100 in. in diameter by 4 ft. stroke of piston.

In the state they now are, no adequate description can be given of the general arrangement, except to say that the cylinders are set amidship, and the air-pumps aft of them; that the steam chests are on the outboard side of the cylinders, where the bonnets can be readily removed, and that expansion valves are provided.

One of the cylinders fell down a distance of 5 ft., while suspended from the shears, which ruined it so that it had to be replaced by one cast for the "Puritan," consort, now building, at Greenpoint, by Thomas F. Rowland. The cause of the disaster was the breaking of the guy ropes which stayed the shears; fortunately, no lives were lost. The company incur a heavy expense by this unavoidable accident; the completion of the ship will not be delayed by the casualty. The overhang of the armour shelves on the sides af the "Dictator," is much less than in the "Monitors," being only some 2ft.; while the projection forward and aft is also less than the same parts in the smaller batteries; we notice that the armour shelves are strengthened by the addition of iron-plate sponsons.

The "Dictator" has an immense screw-propeller, of 21 ft. 6 in. diameter, and 32 ft. pitch; there is no outboard bearing for the shaft. The boilers are six in number, three on each side, and are of the return tubular pattern. The ship herself is 320 ft. in length 50 ft. in width, and 20 ft. deep; there will be two turrets, whose walls are 15 in. thick; outside diameter to us unknown.

The "Dunderberg"—a wooden vessel, immensely thick and strong in the hull—is assuming shape and form as rapidly as human hands can do the work. Mr. W. H. Webb is her builder; and the singular appearance of the hull, as well as the monstrous projecting ram forward, attracts much attention, and provokes criticism from every one, whether competent to pass judgment or not. The whole ship is solid throughout—frames, floor and bulwarks; and with solid casemates, solid plating, guns, engines, commander and crew, she will doubtless prove a valuable addition to our national defences.

There are numbers of other iron-clads building in various parts of the city and suburbs, most of them far advanced towards completion.

THE APPLICATION OF MACHINERY TO COAL-CUTTING.

Mr. Samuel Firth read a Paper on this subject, before the British Association. The following abstract may prove interesting to our readers. While excavating machinery is used with such success in the great Mount Cenis Tunnel, it is not too much to expect its early introduction into our mines, under circumstances certainly not more difficult. Mr. Firth, in the course of his Paper, said:—

Numerous efforts have been made, during the last fifty years, to bring coal-cutting in mines under the influence of mechanical power; but in no case, I believe, except at the West Ardsley Colliery, has any continuous operation survived the experimental period.

I do not expect that the introduction of machinery into coal mines for the purposes named, would materially diminish the number of persons employed, but rather that the effect would be to meet the increasing consumption. That increase may safely be taken at two millions of tons per annum, and to supply this increase would require an annual increase of labourers amounting to about 3,500. Thus there will not be any displacement of labour.

The steam-engine has a 20-inch cylinder, and the air-pump 18 in. The air is worked at a pressure of about 50 lb. to the square inch. The air is conducted down the shaft in iron pipes of 4 in. diameter, and thence to the workings (about 800 yds.) in gas piping, and down the face by india-rubber piping of 1 in. diameter, which is connected to the machine. The machine is moved on iron rails laid on cross iron sleepers, and is propelled a little, after each blow of the pick, by the hand-wheel. Generally, the machine is passed three times over the face of the coal, each time with a longer pick, to gain the requisite depth for taking down. The first cut being 18 to 20 in., the second 9 to 11 in., and the third from 6 to 8 in.; 36 in. being the depth aimed at and accomplished. The actual quantity of work done in six consecutive days of eight hours each, by one man with one machine, was 618¼ yds., or about 800 tons of coal. The man is attended by two boys, who clean out the groove, and remove the coal thrown out by the machine. In the West Ardsley seam a man will average 7½ yds. of coal a day, so that if the machine were worked by shifts of eight hours, three men and six boys would do the work of forty men, and that, too, the most severe and trying work in the pit.

It must be understood that at West Ardsley the seam is somewhat favourable for the purpose. It is 4 ft. thick, having a good roof and floor, and is worked on the long-wall system, with a somewhat soft bareing part, about 12 in. above the floor, and in this the pick works. The comparison, however, with handwork is fairly made, because both work in the same part of the seam. The machine thus far has only been put to "bareing," or "kirving," but the proprietors expect to effect "straight-work" by a different arrangement of the picks. The filling, and all other work of the pit, is untouched by this machinery. The air-power works admirably; and its use gives a cool and refreshing stream of pure air to the far-distant works, which issues from the cylinder at a temperature very little above freezing-point. It will not be necessary to say here that the air-power is acquired by a much larger measure of steam power; but this is not a material item at a colliery, where so much engine coal is almost worthless. I am not prepared with the exact commercial results or saving in cost, but at West Ardsley this part of the question is, I believe, eminently satisfactory. I have been informed that some experiments have been made, within the last few days, at the Hetton colliery, by the West Ardsley machine; and although the seam is of a hard nature, the kirving was done 3 ft. deep with a groove of 3 in. at the face and 2 in. at the back, giving an average cut of 2½ in. high; whereas the average height of hand kirving in the same seam is about 11 in.

This saving of good coal from destruction is equal totan average of 9d. per ton upon the whole yield of the seam.

Another machine of a different principle has been invented at West Ardsley, and promises to be a most useful one. It is on the direct-action principle, with a to-and-fro motion, from a cylinder mounted transversely upon the carriage, and regulated in a similar manner to the pick machine.

This invention has not advanced so far as the "pick," but some recent experiments have given most satisfactory results. The complete success of this machine will be of great importance, as it will be more effective in "straight-work," "headings," and "drilling," than the pick.

In conclusion, I may express the confident opinion that, at no distant period, every branch of mining will be accomplished by machinery; and if we look at those results from a humane point of view, the sooner they are realized the better it will be for all parties, and especially for the working collier.

DECORATING MACHINERY.

The external appearance of some kinds of tools and utensils attracts public attention at once, and provokes criticism of a more or less favourable nature; according as the embellishment is in good or bad taste. In respect to the ornamentation of machines, many different opinions exist. There are a certain class of manufacturers who build their machines without any attempt at decoration, and who reject all outward show, as detracting from the real merit of the article—which lies unquestionably in its capacity to do the work it was designed for. Yet another, and in this country a very numerous class, so overload their mechanism with paint, gilding, and gewgaws, that the appearance becomes tawdry in the extreme, and detracts very materially from the pleasure one experiences in looking at what may be an otherwise well-designed and efficient machine. Some locomotive engine tenders we have noticed, are so covered with a maze of scrolls, scratches, and dabs of paint, beginning nowhere, and ending in the same place, that one cannot but think the ghost of some crazy artist had risen at the dead of night, and wandering at random over the innocent iron, left traces of his revel in wild meaningless blotches and patches, without character or purpose.

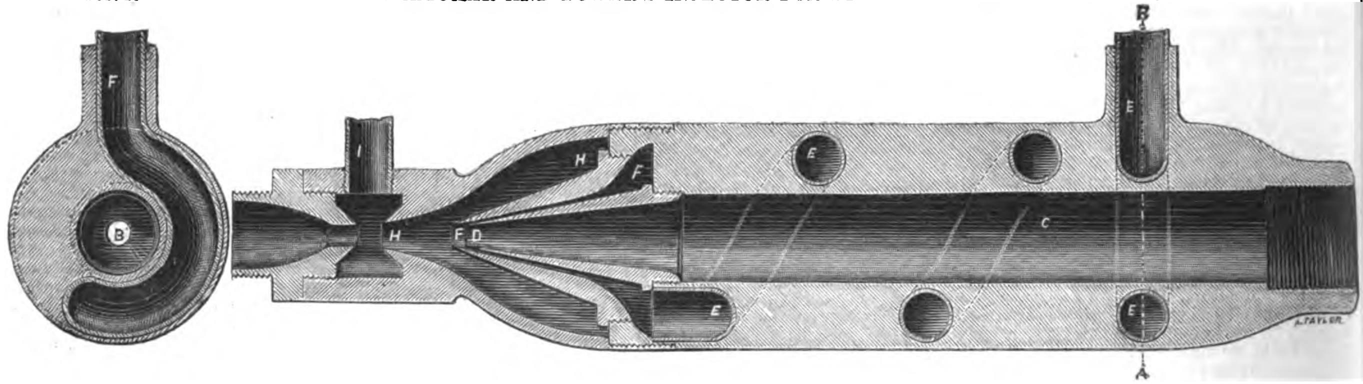
It seems to us that in all cases where the ornamentation of a machine is determined upon, a safe rule would be to consult the well-established laws of design (and common sense also), before perpetrating abortions which will, perhaps, live long after the offender against good taste has departed. All apparatus intended to be placed in an obscure corner, or those parts of machines which are not seen, require no outward adornment; but in other cases, where perhaps hundreds of persons daily use the apparatus, and the whole world, so to speak, criticizes and comments upon its appearance, a tasteful and appropriate exterior adds, not only to the beauty of the machine, but to its value, and is at once a mark of enterprise and an evidence of the maker's cultivation.—*Scientific American.*

IRON AND STEEL EXTRACTED FROM WASTE IRON CINDERS.

We have received a circular from A. L. Fleury, chemist, Franklin Institute, Philadelphia, in which he states that he has succeeded in extracting good wrought iron and steel from the waste cinders of puddling and reheating furnaces, which have hitherto been considered a nuisance in their vicinity. He states that, from chemical analysis, he is assured that such cinders contain from 25 to 50 per cent. of iron, combined with sulphur, silica, phosphorus, and alumina, forming a brittle compound. Near the large ironworks at Troy, N.Y., thousands of tons of these cinders are spread over the roads, and in every 100 lb. there are about 35 lb. of iron. By reworking this cinder with lime and charcoal, iron had been extracted, but it was invariably red-short (brittle at a red heat), as the sulphur, silicon, and phosphorus remained combined with the iron. Numberless unsuccessful efforts had been made to work this cinder economically. Mr. Fleury states that the problem of extracting the iron from the cinder and removing the impurities, was solved by taking advantage of the chemical fact that unslacked burnt lime possesses the property of decomposing silicates during the act of being slacked with water. He mixed a proper quantity of powdered burnt lime, with fine ground iron cinder, wetted the whole with water, and exposed the mixture to the atmosphere. When this compound was dry, it was placed in a common puddling furnace, treated like pig iron, and 50 per cent. of wrought iron was obtained. This product, however, was somewhat red-short, as it contained traces of sulphur, but the impurity—Mr. Fleury informs us—he afterwards extracted, by mixing a chlorine salt with the water which he employed to wet the lime mixed with the cinder; and a good quality of iron, we are informed, can be invariably produced when the operations are properly conducted. It is also stated that the cost of preparing the cinder does not exceed 2 dols. per ton, and the operation of smelting can be executed in puddling, blast, or other suitable furnaces. The invention has been patented in America and Europe. —*Scientific American.*

Mr. Spencer read a Paper (contributed by Mr. Page, the engineer of Westminster Bridge) "On the Foundation of Bridges," at the recent meeting of the British Association. After giving his own experience in such matters, he went on to describe the process of formation. The foundation, he said, might be described as a part of the structure which resisted the weight of the superstructure, and it was evident that the higher the horizontal place of the resisting mass was, the less was the weight of the superstructure upon it, and the better adapted as a foundation to resist its pressure. He then described the system he had pursued in the construction of four bridges over the Thames, and also of the pier at Greenock. He considered it important that the foundations of each pier should be one undivided structure, and should not be broken into separate parts, as it was in cases where cylinders were used; and that, besides the resistance due to the horizontal area of the foundation, it should embrace the additional resistance afforded by the friction due to the vertical surface of the pile, and this, short of founding on rock itself, would present the most solid resisting mass that could be found. The application of this system to harbours of refuge was a subject of great interest and importance at the present time, both for expedition in completing the works and for economy.

FIG. 2. FLETCHER AND BOWER'S INJECTOR FOR STEAM BOILERS. FIG. 1.



FLETCHER AND BOWER'S INJECTOR FOR STEAM BOILERS.

THE following improvements in injectors for steam boilers have been patented by Messrs. J. Fletcher and H. Bower, of Halifax, Yorkshire.

The improved injector consists of one pipe coiled spirally around another pipe, or of a pipe having a straight passage through its centre and a crust sufficiently thick to admit of a spiral passage being formed therein around the centra passage. The spiral passage opens at one end into a water supply chamber, and the other into a discharge or injection chamber, which is to be attached to the ordinary feed pipe of a boiler. The straight passage is connected at the water chamber end to a pipe which opens to the steam chamber of the boiler, and the other end terminates in the discharge or injection chamber at a point near to and concentrically with the outlet or orifice of the feed pipe. This apparatus is provided with taps or valves for regulating the flow of steam and water.

The construction of this apparatus, and the manner in which it is to be applied in practice, will be readily understood by reference to the accompanying drawings, where fig. 1 is a longitudinal section, and fig. 2 is a cross section taken through the line A, B, in fig. 1; C, is the central pipe or steam passage, which is formed at one end to fix to a pipe connected with the steam dome or steam chamber of a boiler, the other end is furnished with a conical jet D, which is of suitable size in its opening or outlet, and a variety of different sizes of jets may be adapted thereto; E is the spiral pipe or water passage, which runs spirally around the other pipe, and terminates in a conical chamber F, which has an outlet concentric with the steam outlet, and also to the disharge pipe or injection chamber H. The apparatus is screwed or may be provided with a flange so as to be connected at this end to the ordinary feed pipe of a boiler. The conical outlets or steam and water jets D and F can be set or adjusted by screwing them in or out; I is a "pet pipe" or overflow pipe.

The action of the apparatus is as follows:—When steam is applied or turned on to the central pipe C, and cold water admitted to the spiral pipe E at the entrance B, the steam sucks or draws the water in, and for a very short time steam blows out at the "pet pipe" I; a vacuum valve is applied to this pipe, which, as the steam becomes condensed, closes and stops the outflow of steam, the water still passing up the spiral pipe E, which, by the time it gets to the conical jet D, it becomes hot or warm enough to be driven by the steam through the feed pipe into the boiler.

This apparatus can be applied, with very little modification and adaptation of the parts, eithe to locomotive, marine, or stationary boilers, and it is also applicable as a force-pump on ship board, in breweries, distilleries, dye-houses, and for other purposes or places where a pump is required, and especially where there is no steam engine or other motive power engine to work an ordinary pump. It will be understood that the quantities and proportions of steam and water let into the respective pipes are regulated by taps or valves.

BLAKELY AND VAVASSEUR'S IMPROVEMENTS IN PROJECTILES.

THE following improvements in projectiles have been patented by Captain Blakely and Mr. Josiah Vavasseur, engineer, Surrey.

The invention consists in forming projectiles with grooves in the body and at the rear end for receiving lead or other soft metal.

The patentees prefer to form these grooves at an angle to the axis of the projectiles, and in the reverse direction to that of the rifling of the gun in which they are to be used, but the grooves may run parallel to the axis, and may be more or less long and deep, according to requirement. When the projectile is ready for use, there are alternate layers or strips of lead or other soft metal and iron or other metal of which the projectile is formed round the circumference thereof, the iron or other hard metal thus protecting the lead or soft metal from injury.

Fig. 1 of the accompanying drawings is an elevation; fig. 2, a similar view, partly in section;

FIG. 2. FIG. 1.

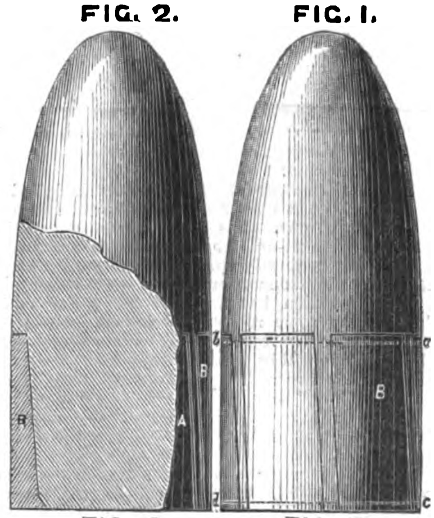


FIG. 4. FIG. 3.

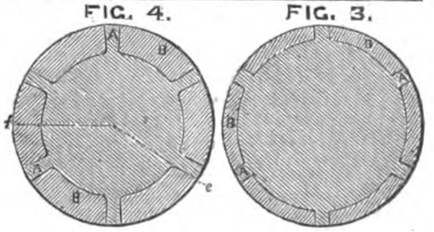

and figs. 3 and 4 are cross sectons, through the lines a, b, and c, d, respectively of fig. 1, of a projectile constructed according to this invention with grooves formed in the body and at the rear end thereof at an angle to the axis of the projectile, and in the reverse direction to that of the rifling of the gun.

A, A, are the grooves which are filled with lead or other soft metal B. They are, b. preference, slightly undercut, as shown, so as the better to hold the lead or other soft metal. The patentees prefer to make the grooves shallower at the fore end thereof than at the rear, as seen in fig. 2, the sectional part of which is taken through the line e, f, of fig. 4.

PRICE'S IMPROVEMENTS IN SIGNAL LANTERNS.

THE following improvements in signal lanterns have been patented by Mr. John Price, of Southampton:—According to the provisions of the Merchant Shipping Act open boats under weigh will shortly be required to show a red light on the left or port side of the boat and a green light on the right or starboard side, and when at anchor will be required to show a bright light all round. Now, a single lantern, constructed according to this invention, can be used for each of these purposes. The lantern is, by preference, made three-sided; the upper half of each side is glazed with white glass, so that when neither of the glasses is covered a white light is shown all round. Fitting freely within the lantern is a trianguar frame, the sides of which are parallel with the sides of the lantern. This frame is of a depth equal to half the depth of the lantern, so that when this frame is in its lowest position it does not cover any of the glazed portion of the lantern. One side of the frame is glazed with red glass, and another with green glass; the third side is provided on its inner face with a mirror, thus when the frame is raised one of the glasses of the lantern will be obscured by the mirror, another will have a green glass behind it, and the third a red glass behind it, so that a red light will be shown on one side, and a green on the other. The frame can be raised by a pin or small projecting handle, which is screwed into the bottom edge of the mirror side of the frame; this pin or handle passes out through a slot in the side of the lantern, which is parallel with the mirror, and the frame when raised is retained in its highest position by a sliding bolt, which is then slid under the pin or handle; this sliding bolt also covers over the slot in the side of the lantern, to prevent too great a draught on the lamp. The side of the lantern which is parallel with the mirror is provided with handles, so that the lantern when held out in front of any one facing towards the bow of the boat, will show the proper light for each side. The top of the lantern is made capable of turning back on a hinge, so that when the pin or handle, if the interior slide is removed by unscrewing the slide, may be taken out at the top of the lantern, in order that the mirror and glasses may be cleaned. The lamp is inserted into the lantern through a hole in the bottom of the lantern, as is usual in signal lanterns.

Fig. 1 of the accompanying drawings shows a front view of a ship signal lantern constructed according to the invention; fig. 2 is a back view; fig. 3 is a vertical section, and figs. 4 and 5 are horizontal sections, taken respectively at the dotted lines (1), (1), and (2), (2), fig. 1.

a, a, a, is the frame of the lantern, which is, by preference, made with three sides a^1, a_2, a^3; the upper half of each of these sides is glazed with white glass. Within the lantern is the frame b; this frame is glazed on one side with red

PRICE'S IMPROVEMENTS IN SIGNAL LANTERNS.

FIG. 1.

FIG. 4.

FIG. 2.

FIG. 5.

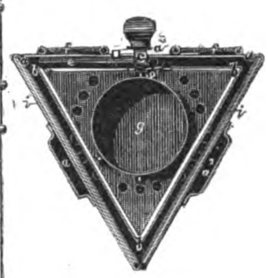

FIG. 3.

glass, on another with green glass, and on the third side the frame is closed and not transparent; but it is preferred to have a mirror or reflector on this side. The frame is capable of being moved up and down by the small projecting handle *c*, which moves in a slot *d* formed in the side a^3 of the lantern, but the raising or lowering the frame may be by other convenient means. The frame *b* is retained in a raised position by moving the sliding bolt *e* under the small projecting handle *c*, or the part may be otherwise retained in position. When the frame *d* is in a raised position, and the lantern is held by the handles *f*, *f*, a red light will be shown on the left or port side, and a green light on the right or starboard side, the light being prevented from passing out of the third side. When the frame *b* is in its lowest position a white light will be shown all round the lantern. The sliding bolt *c* also serves to cover the slot *d* when the frame *b* is in a raised position. *g* is the lamp, which is inserted into the lantern through a hole in the bottom thereof, and is held securely therein by the small projections g^1, g^1, which in introducing the lamp into its place pass through slots in the sides of the hole, and then the lamp is fastened in its place by turning it partly round. The top of the lantern is hinged to the upper part of the side a^3, and *h* is a small hook for securing it when closed. The sides a_1 and a^2 are provided with metal slides *i*, *i*, to obscure the light when necessary.

BATES' IMPROVEMENTS IN CANNON.

Mr. Benjamin Franklin Bates, of Morley's Hotel, London, has recently patented the following improvements in cannon.

In constructing cannon, according to this invention, a hole is formed through the breech end; this hole is smaller than the bore, and is parallel and concentric with it. Each projectile is provided with a long rod or bar, which in loading the cannon is passed through the hole in its breech; at the front end of the rod is an enlargement or head, which, however, is smaller than the bore; this head may be solid, or it may be formed into a shell; behind this enlargement is placed a loose disc which fits the bore accurately; the pheriphery of this disc may, if desired, be ormed of soft metal, and may also have lubricating material combined with it; the rod at the rear end of the projectile is, by preference, polygonal in section, with each of the sides winding spirally around the rod from end to end of its length, as though the rod were twisted; the hole in the breech end of the cannon is formed to fit and correspond with the bar, so that when the piece is fired, the projectile, in addition to being propelled forward, will at the same time be caused to revolve on its axis. The loose disc behind the head of the projectile, by preference, does not rotate with the projectile, but the rod of the projectile turns in a hole in the disc; as soon as the projectile leaves the gun, the resistance of the air will cause the disc to slip off the bar at its rear end, or the disc may be made to separate into two or more pieces as soon as it leaves the gun. If desired, the hole through the breech end of the gun may be closed, as soon as the rear end of the projectile passes out of it, by means of a sliding piece pressed forward for that purpose by a spring. The hole in the breech end of the gun may be provided with a close-fitting plug; the gun can then either be used to propel a shot, such as above described, or when the plug is fixed in the hole the gun may be used as an ordinary smooth-bore gun.

Fig. 1 shows a section of a cannon constructed according to this invention; fig. 2 shows the breech end of the cannon.

BATES' IMPROVFMENTS IN CANNON.

FIG. 2.

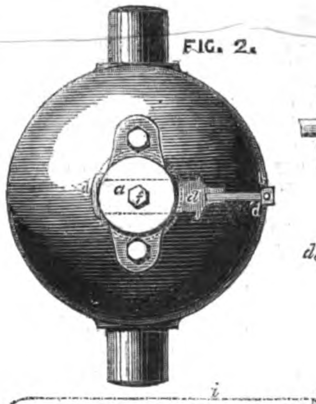

FIG. 1.

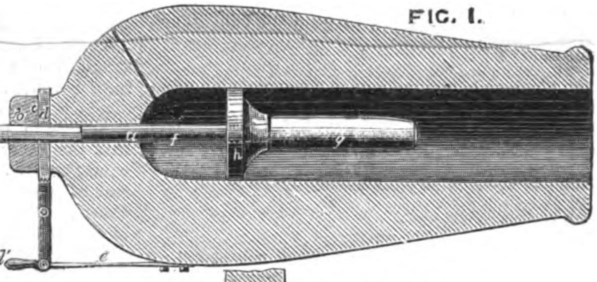

FIG. 3.

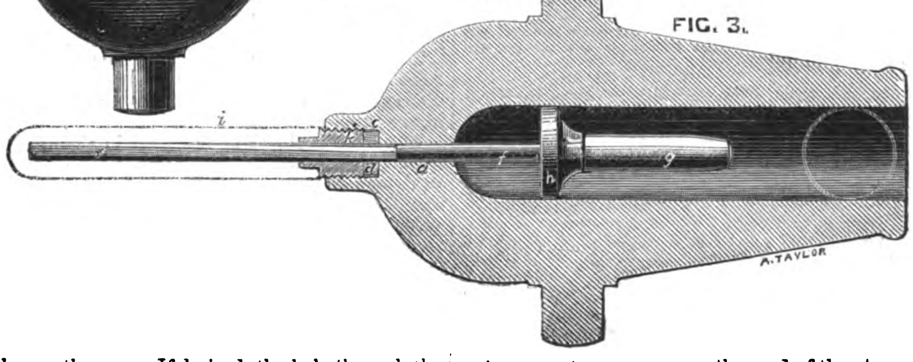

a is the hole at the breech end of the cannon; this hole is, by preference, made sufficiently large for the rod or stem of the projectile to pass freely through it, and behind the breech is bolted (as is shown at fig. 2) a piece *b*; this piece has also a hole made through it sufficiently large for the rod or bolt to pass through freely; through the piece *b* is a slot *c*, in which is a sliding piece *d*, made of steel; in this sliding piece is a hole, which accurately fits the rod or stem of the projectile; the slide *d* is constantly pressed on by a spring *c*, so that, as soon as the end of the stem or rod passes beyond the hole formed in the slide, the slide will be moved forward so as to stop up the hole through the breech. In loading the gun this slide is held down by the handle d_1, so that the hole in the slide shall correspond with the hole in the breech, there being stops on the slide which prevent it being lowered too far; the projectile is inserted at the muzzle of the cannon, and is pressed home in the ordinary way; the powder is, by preference, contained in an annular bag or case, so that the rod of the projectile may be inserted through it before the projectile is

placed in the gun. *f* is the stem or rod of the projectile, at the foremost end of which is the head *g*; this head, as above stated, may be solid, or it may be formed into a shell; the front end of the head is shown in the drawing to be shaped like the head of a punch, but it may be made rounded or otherwise formed; the rod or stem is of a section to fit the hole in the slide *d*; this hole is, by preference, six-sided, as is shown in fig. 2, but it may be of other form; the portion of the rod that passes through the hole is twisted from end to end of its length, as is seen at fig. 3, so that when the projectile is fired from the gun it will be caused to rotate on its own axis; *h* is the loose disc at the back of the head of the projectile, the periphery of which is made to fit the bore of the cannon. The disc is shown at figs. 1 and 3, to be in one piece, but it may, as before stated, be made in two or more pieces, so that it may readily separate as soon as it passes out of the cannon. Fig. 3 shows a cannon constructed in such a manner that the piece *d*, through which the hole is formed that corresponds with the section of the rod of the projectile, is held stationary, in place of having a sliding motion given to it, as in the arrangement just described; the piece *d*, in the arrangement shown, is held in its place by the screw plug *k*, and is prevented from turning by its being formed hexagonal on its outer circumference, and fitting within an hexagonal hole formed to receive it.

Meetings for the Week.

SAT.—*London Association of Foremen Engineers.*—" On an Entirely New Method of Coating Telegraph Wires," by Mr. Miller, at 8 p.m.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post-office orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

All communications should be addressed to the EDITOR, 166, Fleet-street.

RECEIVED.—C. G.—W. H.—S. B.—D. G. F.—C. F. Y.—S. T.—Z. C.—H. R. E.—R. A.—A. L.—J. H.—J. W.—W. W.—Capt. S.

NAUTICUS.—Next week.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Could you recommend us some good and cheap way of warming our place of worship? It is 17½ yds. long by 10½ wide, no gallery; was built five years ago. If you can give me the address, or refer any maker to me, you will oblige

Yours truly,
56, Hope-street, Wrexham. CHAS. HUGHES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Do you consider a 1 inch chain sufficiently strong for a crane to lift 10 tons?—By answering the above question you will greatly oblige

Yours truly,
Leeds, Sept. 21, 1863. D. R.

[If the chain works over a double tackle pulley it is strong enough, not otherwise.—ED. M. M.]

Correspondence.

[*We do not hold ourselves responsible for the opinions of our correspondents.*]

TORPEDOES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—By the recent discussions upon the properties of gun-cotton, we have, to some extent, been enlightened on the subject of torpedoes.

The sentiments of Capt. Maury as to the employment of such destructive engines, as a means of defence, must, I think, be generally accepted. A Confederate, owing allegiance to the Confederate States—serving in defence of Charleston—would be justified in his endeavour to hoist to the clouds any Federal vessel that might come into the harbour of Charleston upon the compassionate mission of destroying the town—burning or horribly mutilating its inhabitants. In summarily disposing of the invading foe, the Confederate would not be diverted from his purpose, though depending upon the aid of his Satanic Majesty.

Those who have looked into the histories of engines of war, have learnt that any mode of destruction, that was not in keeping with the prejudices of the day, was proscribed as villanous. Gunpowder and guns were abhorred by the warriors of old; torpedoes, in turn, appear to be held in about the same estimation by warriors of this day. But, taking a common-sense view of the matter, we cannot fail to see that, when men set about fighting in right good earnest, there is no restraint upon the disposition to finish off each other by any available means which they may respectively possess—either in the material, or in the science, art, or strategy of war: so it will be, as it has ever been, during the existence of pugnacious man.

With regard to the explosion of the torpedo in the River James, it could not, I think, have been in hugging contact with the vessel intended to be destroyed when it exploded. A very much smaller charge than 1,000 lb. of gunpowder would have been sufficient for the purpose, if properly exploded. There is not, however, a doubt that a more violently explosive agent than common gunpowder is better adapted to the charging of torpedoes; for the effect of gunpowder in relation to the more violently explosive agents, is as pressure to percussive force. From what has been stated of gun-cotton, it is likely to do its work effectually, even under the disadvantage of the torpedo not being, when exploded, in *contact* under or alongside of the vessel attacked. Like results would, I confidently believe, obtain, under similar conditions, by the employment of Horsley's powder, which, for such work, is, I think, the more desirable agent of the two.

Torpedoes may be of any suitable form and strength of material. If made of stout boiler iron, I would recommend their being of a size to displace, when charged, a quantity of water a trifle less in weight than their own weights, so that they may require only small buoys to suspend them at any desired depth below the surface of the water. It may be desirable that, in charging torpedoes, they should not be completely filled by their respective charges; the space occupied by the charge may be partitioned off by a slight diaphragm, keeping the charge at the bottom of the torpedo, and so ensuring the perfect action of the exploding apparatus.

The means of exploding by galvanic arrangement may be found to answer under certain conditions, but I think there is a better means—a means generally applicable.

When the problem of the torpedo shall have been solved, it will be found that it can be very easily and effectively managed in "blue water," and that it will be better to encounter invading vessels at sea than wait till their arrival in rivers or harbours.

I remain, your obedient servant,
JN. HARVEY, Capt. R.N.
5, Keynsham Parade, Cheltenham,
Sept. 19, 1863.

STEAM BOILER EXPLOSIONS.

Sir,—You appended a foot-note to my letter last week as follows:—"We have inserted Mr. Hopkinson's letter, though we are at a loss to understand its object."

My object was to have inserted that portion you omitted, and instead of saying "your contemporary, the *Engineer*," you should have said "Mr. Zerah Colburn, the editor of the *Engineer*." I intended to convey to your readers that Mr. Colburn was not entitled to the praise he was continually lauding upon himself, regarding his great discovery of the explosive properties of water; but, as the name was omitted by you, my object was not attained.

Your remarks remind me of a circumstance which occurred some years ago. I wrote a letter on this subject, which I forwarded to the two Manchester daily papers. One editor published the fore part of the letter, and appended a footnote that the latter part of the letter did not apply to the question; and the other editor published the latter part of the letter, stating that the fore part did not apply to the subject, and betwixt the two papers the whole letter appeared.—Query, Which of the two was right?

In your case there cannot be any query, providing you be the judge; therefore, taking for granted that you were right, I perused your article on "Boiler Explosions," to obtain further information, and found that your conclusion was—"That this store of power is nothing but a store of heat." This I have long known; but I am waiting to know what heat is; and if you or your readers will define what heat is, "the boon will be conferred upon the scientific world."

The fact is, Sir, that Mr. Colburn has been endeavouring to make us believe that the explosive property of water when charged with heat, was discovered by him in 1859 and unknown before. A country editor of ours, viz., the *Huddersfield Chronicle*, in 1857, in a leading article on boiler explosions, uses these words:—"By these means the internal contents of the boiler—the steam and the water—charged with a high degree of pressure or heat, became suddenly liberated; and these possessing immense *expanding* force, exerted that force, and produced the disastrous results before described."

In my report to the coroner and jury on the same explosion alluded to in the former extract, were as follows:—"In my opinion, at the time of the bursting, the pressure in the boiler would be somewhere betwixt 75 and 100 lbs. to the square inch, the water being at a temperature from 310 to 330 degrees. The flue and ends appear to have been shot straight out, and not against the roof of the boiler-house. The cause of the building falling would be from the expansion of the steam and water on their release from the boiler, charged with such a high degree of heat."

Mr. Fairbairn, who followed in his evidence on the same occasion said:—"The former collapsed from compression on its exterior surface, and the fracture which gave vent to the elastic power of the pent-up steam was quite sufficient to account for the results that followed—namely, the demolition of the buildings, and the projection of the boiler, flues, &c., into the positions in which they were found."

Therefore, taking recent dates, say 1857, and omitting former authorities, we stand in order thus:—

1. Editor of *Huddersfield Chronicle*.
2. Myself.
3. Mr. W. Fairbairn.
4. Mr. Zerah Colburn.
5. Mr. D. K. Clark.
6. The Astronomer Royal.

Yours respectfully,
J. HOPKINSON.
Britannia Works, Huddersfield,
September 22, 1863.

GUNS FOR THE NAVY.

SIR,—On reading the excellent article on "Guns for the Navy" in your last number, in which you recommend such a moderate rifling as "to impart just such a velocity of rotation and no more, to an elongated projectile, as will secure it from turning over in its flight," it occurs to me that the desired rotation might be obtained by discharging a Whitworth projectile from a smooth-bore. If the air is able to destroy a great part of the motion of the projectile, much more will it be able to modify that motion, and impart a moderate rotation to the shot, by impinging on the twisted hexagonal planes of its exterior.—Yours, &c., R. A.

Edinburgh, Sept. 23, 1863.

Miscellanea.

A project has been broached in New York for paving the streets with iron and conducting the traffic by steam carriages moving on these iron floors. It is urged that the saving to clothing, furniture, and goods from damage by dust and mud would be enormous; that the resistance on clean iron floors would be small, the wear on carriages slight, and the noise but trifling in comparison with what it is at present. Shoes, it is represented, would wear much longer on iron side-walks than on stone.

Preparations are now being made by the contractors for commencing the construction of the large semicircular casemated fort at the entrance of the Medway, which is intended to guard the passage to Chatham harbour, the foundations having been completed some time since, and a sufficient period allowed to elapse to secure their consolidation. The position of the fort will enable it to effectually bar the passage of any ships attempting to approach either Sheerness or Chatham dockyards. It is intended, on the completion of this and the other forts which command the approaches to the Medway, to arm them with the most powerful description of guns, throwing the heaviest projectiles, recent events at Charleston proving that forts are only superior to ships in exact proportion to the description of armament used.

The Atlantic Royal Mail steamship "Adriatic," on her recent outward voyage, made the run from Galway to New York in ten days four hours, including detention to land mails and passengers at St. John's, Newfoundland. This is 24 hours under the contract time.

The New York papers describe the experiments made by a Mr. Solomon Andrews, of New Jersey, with a new flying machine. Its form is that of three cigars pointed at both ends, secured together at their longitudinal equators, covered by a net, and supporting by 120 cords a car 16 ft. below under its centre. The car is 12 ft. long, made of basket work, and is 16 in. wide at the bottom. The aërostat, or cylindroids, are made of varnished linen, like ordinary balloons. On Friday, the 4th instant, he made his last experiment, and demonstrated to an admiring crowd the possibility of going against the wind, and of guiding her in any and every direction with a small rudder having only 17 square feet of surface. After a few short flights, to satisfy himself and a few friends that all was right, and that she would do all he had contemplated, he set her off in a spiral course upward, she going at the rate of not less than 120 miles per hour, and describing circles in the air of more than 1½ miles in circumference. She made twenty revolutions before she entered the upper strata of clouds and was lost to view. She passed through the first strata of dense white clouds, about two miles high, scattering them as she entered in all directions. In her upward flight could be distinctly seen her rapid movement in a contrary direction to the moving clouds, and as she came before the wind passing by them with great celerity. As she was distinctly seen thus to move, both below and above the clouds on the clear blue sky at five o'clock p.m., with the sun shining clear upon her, there could be no mistake or optical delusion to the beholder.

The steam-rams at Birkenhead are rapidly approaching to completion. "El Tousson" wants but little to fit her for taking stores; "El Mounassir" is not far behind; both the rams are as well-designed for swiftness as for strength. Their length each is 230 ft., their beam 42 ft., and their extreme depth less than 20 ft. The burden is about 1,500 tons register, and the draft of each vessel when loaded will be some 15 ft., being about 6 ft. above the water-line, all the intermediate surface being protected, first, by a coating of teak over the iron skin of the ship, and then by armour plates over that, each massive scale being 5½ in. thick. All this armour is dove-tailed together so accurately, that the joints are scarcely perceptible. The deck is of 5-inch teak, covered with iron, and the bulwarks are also of iron, being so made as to let down outwards, and thus to clear the decks during action. Two revolving cylindrical turrets, on the well-known principles invented by Captain Coles, are apportioned to each ship, one turret being before, and the other abaft her engine-room. There is also a pilot-house, strongly built of teak, and iron-plated. Each turret carries two guns, placed in close proximity, so that they can be brought to bear nearly in the same position at one time. In the case of the "Mounassir," one turret is being fast completed on a spot situated at some little distance from the hall; and the plan of construction, being at present laid bare, cannot but raise admiration in every beholder. Its wall is a series of cellular spaces, like the chine of a shell-fish, and all these iron cells are to be filled up with teak, making one solid and uniform mass, which is to be again strengthened and rendered well nigh impregnable by armour plates. At each end of the vessel is a raised deck, forming tolerably commodious quarters for officers and men; and the forecastle is made to carry one or two heavy guns, if they be needed. In the captain's cabin are port-holes for two 32-pounders; and each ram has capacity for 300 tons of coal. The machinery, as a matter of course, is all below the water-line. In one of the storehouses are the telescopic iron masts and yards of the two rams, which, as it seems, are to be barque-rigged. Their sterns will be so formed as to protect the screw and rudder from shot or collision.

During the furious assault upon Fort Sumter, the first shot fired from the 200-pound Parrott rifle penetrated 9 ft. into the wall facing Sullivan's Island, after first passing through the gorge wall of the fort; it knocked over a pile of brick upon a steamer outside of the wall, demolished its smoke-stack, and caused the boiler to burst, by which casualty four negroes were killed.

The "Great Eastern," which arrived at Liverpool on Sunday morning, while off Cape Clear on Friday evening, ran down a ship called the "Jane," Captain Duff, bound from Liverpool to Quebec. Two of the crew of the latter were unfortunately killed by the collision. The "Jane" left Liverpool on the 6th inst.

The effective measures adopted to stop the lamentable fire in the Wellington coalpit at Whitehaven are fast approaching completion. A drift has been cut from the up-cast shaft to the sea, and there is a communication from the beach to the pit. It is expected that in a few days the fire will be entirely subdued.

The large fort now in the course of construction at Portsmouth, near Southsea Castle, is to be provided with a cupola shield, on the plan patented by Captain Cowper Coles.

American green-back bank notes are coloured with green ink, which cannot be photographed nor dislodged by alkalies.

During the last few days the holders and speculators in petroleum at Rotterdam have been thrown into a state of the utmost consternation and excitement, owing to the surface of the water in the river and canals being covered with petroleum, that must have escaped by leakage. During May, June, and July, large quantities of the commodity were imported and duly stored in the bonded warehouses of the city. It is now ascertained that a frightful quantity must have escaped, for not only are the river and canals covered with it, but it has penetrated into the wells, and impregnated the water in them with a most unpleasant taste. Not only is there no good water to be had for drinking, but the populace expect a general conflagration of the city from the incautious application of a lighted candle, or even a match falling in the water anywhere. The price of the article has already risen 20 per cent., in consequence, and a further advance is confidently expected.

The two large masses of rock in the Menai Straits, known as the Cow and Calf Rocks, and which have for so long impeded the navigation of the Straits, are now about being removed. Several masses have been blasted and taken up under the direction of Mr. W. B. Hicks, of Falmouth, who, with a number of other divers, is making rapid progress with their removal.

The *Toulonnais* says:—Private accounts from Pais announce that a certain number of iron-clad vessels, designated by the name of "Bull-dogs," are about to be put on the stocks. This kind of vessel will be, it is said, a complete event in naval architecture, and they will be constructed on an improved plan, resulting from the examination of a dozen projects of different kinds, from which that considered as the best has been selected.

Last Tuesday, an action was brought in the Manchester County Court, before Mr. W. Saunders, deputy judge, the plaintiffs being Messrs. Perera, Spanish merchants, Deansgate, and the defendants Messrs. Bellhouse, engineers. The action was brought to recover £50 for damages sustained by reason of the breakage of an hydraulic press furnished by the defendants. In 1858 the plaintiffs supplied two presses and pumps to the defendants, at £120 each press. The rams were to be 10 in. in diameter, and the pumps and presses were to be of a first-class character, and capable of sustaining a pressure of 3 tons to the square inch. The machines were put down and paid for, and appeared to work well till the 6th of July. On that day the bottom of one of the presses broke with a tremendous crash; the top and pillars flew off, the foundation was injured, and great damage was done. On examining the fragments of the machine, it appeared that the middle of the press bottom, which should have been the strongest portion of the machine, was the weakest. It had a large flaw, the iron was spongy, and the casting appeared to have been weakened by what seemed to be a lengthening. The pressure at the time of the accident was only 2 tons 9 cwt., which was the highest the machine had ever been worked at.—A number of practical and consulting engineers were examined on each each side, and their evidence was very conflicting. The plaintiffs' witnesses swore that the machine was so lightly constructed and so made that it was impossible to sustain a pressure of 3 tons. On the other hand, the defendants' witnesses proved that, making full allowance for the defective casting, the machine was quite capable of sustaining a pressure of 6 tons. They attributed the cause of the accident to a fracture, which had probably arisen months before the accident, through what was possibly carelessness in the use of the machine.—The case occupied the court about five hours; and, as it presented a large number of points for consideration, the learned judge reserved his decision.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

420. R. A. Brooman. *An improved cover or protection for steel and other metal springs, ribands, and hoops.* (A communication.) Dated February 16, 1863.

This invention is intended chiefly to apply to protecting or covering the metal ribands used in the manufacture of "crinolines," but it applies to metal springs, ribands, and hoops generally. It consists in winding spirally on such springs, ribands, or hoops, one or more strips of paper, stamped, coloured, or plain, or in encasing the springs, ribands, or hoops in sheaths of paper or papier mâché. *Patent completed.*

421. W. Jackson. *Improvements in pumps.* Dated February 16, 1863.

This invention is intended chiefly to apply to ships' pumps, but it is applicable to pumps in general. The inventor causes the suction pipe to terminate at top in a bend, and at the bottom of the bend he fixes a box; at right angles (or nearly so) to this box, he fits the pump barrel; the bucket is connected by a rod to one end of a rocking beam. The other end of this beam is furnished with a friction roller, and the beam is made to rock or reciprocate, so as to communicate the requisite motion to the bucket by means of a cam mounted upon a shaft, to which rotary motion is communicated by a crank handle or otherwise. *Patent abandoned.*

422. J. H. Haywood and W. Vernon. *Improvements in packing bonnet fronts, rouches, and other similar articles.* Dated February 16, 1863.

This invention consists in constructing a spindle or spindles of any required size and shape, and composed of wood, paper, or other material, and of the requisite length of or for the articles to be packed, upon which spindle or spindles the inventors fix two or more pieces of

perforated cork, india rubber, or other material to form cushions, to which these articles are attached by tacks, pins, or hooks; or they fix upon these spindles two or more collars of tin, pasteboard, or other material, in which are punched any required number of slits or grooves, into which the goods to be packed are placed. And, further, to protect the articles from pressure in carriage, transit, or otherwise they fix pieces of wood, wire, pasteboard, or other material of different shapes at the ends, and at intervals on the spindles, and of such length that the ends protrude beyond the articles, and which also hold two or more longitudinal pieces of wood, pasteboard, or other material, which will produce the goods lengthwise. *Patent abandoned.*

423. S. W. CLOUGH. *Improvements in signalling on railways.* Dated February 16, 1863.

This invention consists—1, in the combination of a signal light or lights with apparatus to be worked by the passing of an engine or train over the rails of a railway, whereby the cover or covers will be withdrawn from a lamp or lamps, and allow the same to be displayed to view by the pressure of the engine or train on a piece of metal let into a recess formed in the rail. 2, The invention consists in the adaptation to railway carriages of lamps fixed either in the roof or to the side or sides thereof, so as to be capable of displaying a signal light by the removal of a cover from the lamp. The cover in this case is removed as required by means of a rope or cord connected to one end of a lever, the other end of which is connected to the cover, such rope or cord being attached to a crank shaft running the whole length of the carriage, intended to be pulled by passengers when required. *Patent completed.*

424. W. NALDER. *Improvements in rotary screens, and in the machinery or apparatus employed in the manufacture of such screens.* Dated February 16, 1863.

This invention relates—1, to an improved construction of rotary inclined screen, whether of a cylindrical or polygonal section, and consists in the introduction into the interior of the screen of a metal or other cylinder or drum, extending either entirely or partly along the length of the screen. This internal cylinder or drum is carried by the spindle of the screen, and revolves with it; it is closed at the upper end, and is of smaller diameter than the interior of the screen, so as to leave an annular space of convenient width between it and the screen, to allow of the passage of the corn or other substances to be screened. The object of this internal cylinder or drum is to prevent the corn or other substances from being unduly agitated by the rotation of the screen, and to keep it down upon the screening surface. It is adjustable on the spindles, so as to be capable of being shifted to any desired portion of the length of the screen. The second part of the invention relates to certain peculiar constructions, arrangements, and combinations of machinery or apparatus for manufacturing cylindrical or polygonal rotary screens of wire of any section, or other suitable material, whereby considerable economy in their manufacture is obtained, with a better and more perfect article. *Patent completed.*

425. T. WILKINSON. *Improvements in machinery or apparatus for singeing pigs.* Dated February 16, 1863.

This apparatus consists of an iron chamber, open at both ends, and having its interior longitudinally furnished on opposite ends with tubes perforated so as to emit jets of gas. Sufficient room is left in the centre of this chamber for the carcases to pass through between the gas jets on either side. Running longitudinally through the chamber, and near the top—which has an arched roof—is a track supported on uprights at either end, upon which is placed a small truck, and this truck is set in motion by an endless chain passing through the chamber. The chain runs through wheels at both ends. The pigs are hung from the truck, and the motion which the wheels of this truck acquire in passing along the track communicate to the carcases hanging from the truck a rotary motion while passing through the chamber between the ignited gas jets, so that on issuing at the opposite end they are perfectly singed. The whole machinery is put in motion by a windlass in immediate connection with the endless chain. The gas is supplied to the jets by a single large tube on either side. *Patent abandoned.*

426. T. W. SALMON. *Improvements in washing machines.* Dated February 17, 1863.

This invention consists in the combination of a moveable box to contain the clothes or articles to be washed with a reciprocating frame, the relative motions of such box and frame in opposite directions being adapted to wash the clothes or other articles with increased rapidity. The bottom of the box on which the clothes or other articles are placed is formed or furnished with a series of flutes or cross bars, with spaces between them, and the bottom of the reciprocating frame is also formed or furnished with similar flutes or cross bars, also with spaces between them, the clothes or other articles being placed between the two operating surfaces of the box and frame. The box rests on friction rollers mounted in a stationary frame, or is mounted on rollers running on such frame, and is worked to and fro by means of a lever having its fulcrum in fixed standards. The reciprocating frame is also connected to the said lever, and is suspended on two cross shafts or axes resting on the said fixed standards. By this combination of mechanism the required relative motions are imparted to both the box and the reciprocating frame by working the said lever. The reciprocating frame is adjusted as to its distance from the bottom of the box by raising or lowering the standards on which its cross shafts or axes rest, and fixing them at the required height. *Patent completed.*

427. J. LEE. *Improvements in ploughs and harrows.* Dated February 17, 1863.

This invention consists—1, in forming the handles and beams of ploughs of wrought iron gas tubing or piping, such as at present commonly used by gasfitters, the object being to lessen the weight of ploughs, without lessening the strength and durability thereof. This invention consists—2, in forming harrows of gas tubing, arranged in four or more separate squares, each connected at the centres of their inner sides by links, and in imparting to the said squares a side movement. *Patent abandoned.*

428. W. T. DIPR. *An improvement in brewing.* Dated February 17, 1863.

Hitherto it has been the practice in that part of the operation of brewing known as mashing to use the malt at a temperature as low as that of the surrounding atmosphere, and for the purpose of obtaining the malt cool where fresh malt has been used it has been allowed to remain some time after the malting to become cool. Now, the inventor has discovered that better effects are obtained by using the malt at a temperature of from 80 to 120 degs. Fahr.; and this invention consists in the employment of malt for the purpose of mashing raised to a temperature of from 80 to 120 degs. Fahr. He prefers for the purpose of the invention to erect a drying or heating kiln adjacent to the mash tun, and having raised the malt to the required temperature as above-named, he passes it through rollers to be crushed directly into the mash tun. *Patent abandoned.*

429. W. C. FORD. *An improvement in paddle-wheels.* Dated February 17, 1863.

In carrying out this invention, the inventor makes use of a wheel with arms and rings, in any usual manner, but instead of all the buckets being equidistant from the centre, he places them in three ranges, so that each alternate arm carries two buckets, while each intermediate arm carries one bucket midway, or nearly so, of the other two, in order that it may act against the water that passes between the two preceding buckets. He also makes the buckets of a prismatic form, in order that they may shed off the water more quickly as they rise, and also that their action in the water shall be that of an inclined plane forcing the water away from the wheel, and making it more dense for the paddles to act against, instead of rising within the wheel in a form as heretofore. He also makes the said prismatic buckets of sheet metal, with an armhole for access in making repairs, and the sheet metal ends of these prismatic buckets are made with flanges, by which the buckets are secured in place. *Patent abandoned.*

430. J. GIMSON. *Improvements in presses for punching or cutting out leather and other substances.* Dated February 17, 1863.

This invention relates to that description of presses in which knives or cutting tools with sharp edges, bent in any desired form, are used to cut out pieces of particular shapes. These cutting tools are usually made about two inches deep, and two, three, four, or more tools are frequently adapted to the same press simultaneously, in order to economize time and labour; but, as the knives or cutting instruments, and also the under blocks, do not always wear away equally, great difficulty is experienced in using in the press at the same time several knives and blocks of different depths or thickness. The object of this invention is to obviate the inconvenience arising from using knives and under blocks of different depths or thickness, and to this end the patentee adapts to, or employs in combination with, the moveable part of the press as many adjustable pressing surfaces as there are knives or cutting instruments, so that each pressing surface may be adjusted separately to suit the knife with which it is intended to be employed. He prefers that this adjustment should be made by means of adjusting or set screws, so that the pressing surfaces may be screwed up or down, according to circumstances. *Patent completed.*

431. E. DEVILLE. *Improvements in floating or life preserving coats or garments.* (A communication.) Dated February 17, 1863.

This invention relates to a combination of parts whereby a person unable to swim may be supported in the water above the armpits in a vertical position, without the possibility of sinking, even supposing he should endeavour to do so. These parts are two in number, and consist—1, of a tunic having a skirt formed of two thicknesses of material united together as hereinafter described, the intervening space being filled with from 4 lb. to 5 lb. weight of cork cut up in small pieces; 2, of the ballast, varying in weight from 2 lb. to 8 lb., which is placed on the legs above the ankles. The tunic or body and shirt thus padded with cork will support the body out of water. The ballast being placed near the feet keeps them down and maintains the body in a vertical position as in diving dresses. *Patent completed.*

432. J. DURANT. *Improvements in chimney tops.* Dated February 17, 1863.

We cannot here give space to the details of this invention. *Patent completed.*

433. G. HOME. *Improvements in projectiles.* Dated February 17, 1863.

This invention consists in making apertures, depressions, or cavities in the bullet, and inclined in such a way that the gas of explosion acting upon their closed ends gives a rotary motion to the projectile. *Patent abandoned.*

434. J. W. LANE. *Improvements in fastenings for studs, sleeve fasteners, solitaires, bracelets, brooches, and other uses.* Dated February 17, 1863.

This fastening consists of two parts, one part being a box containing the fastening or locking mechanism of the kind hereafter described, and the other part containing a projecting piece or shank which is to be fitted or locked into the box. The box is provided with an orifice, through which the shank can be introduced, and at each side of the orifice spring catches are provided, which consist of latch or catch piece or pieces which are bent or formed with a "bridge," in order that the inner end of the latch or catch may be kept flat against the inner surface of the box part hereinbefore mentioned. The outer ends of these catches or latches project through orifices beyond the edge of the box part. The shank on the other part of the fastener (such shank having a groove or notch therein) has to be introduced by pressure into the proper orifice, and by the action of the latches or [illegible] becomes locked or fastened, unfastening being effected by pressing the ends of the latches or catches aforesaid. The latches or catches are secured to the box by screws or studs, situate in cuts or openings, and are acted upon by springs. *Patent abandoned.*

435. S. PLUCHART. *A new kind of food for horses.* Dated February 17, 1863.

This invention consists, principally, in preparing food for horses, of straw, hay, or other fodder or forage cut into chaff, of pounded, crushed, bruized, or pulverized oats, gluten, and salt, to which is also added (likewise in the crushed, pounded, bruised, or pulverized state) horse beans, barley, linseed or linseed cake, Indian corn, buckwheat, beet root, potatoes, or other edible vegetable products suitably cut into chaff, pounded, crushed, bruized, or pulverized, according to their nature, and further pulverized bones, or suitable calcareous salts, drastic, or other suitable medicinal products, according to the effect to be obtained. The various substances are to be well mixed together, pressed into balls, bricks, or other suitable forms, and allowed to dry, more or less, as required, and given to the horse in that state, or broken into pieces, pounded, or mixed up with water or other liquid in the cold or warm state. *Patent abandoned.*

436. H. TOMLINSON. *Improvements in stoves or fireplaces for warming apartments.* Dated February 17, 1863.

According to one modification for carrying out this invention, as applied to an open or closed grate, a lateral grating or series of bars is made in each side of the fire-holding portion of the grate, through which gratings a considerable proportion of the products of combustion pass into a lateral flue partially surrounding a hot-air chamber formed in each of the cheeks of the stove—that is, one on each side of the fire. These lateral flues or passages open into horizontal flues at the upper part of the stove, and communicate respectively with two branches of an external arched flue provided with dampers, and fitted on to the top plate of the stove, the crown of the arched flue having a transverse partition made in it to keep the two lateral flues separate until they both unite in one common flue at the crown of the arch. A transverse partition is also placed across the mouth of the main aperture from the body of the fireplace from front to back, such partition extending across the middle of the horizontal flues above referred to, so as to divide such flues transversely. The front and back portion of these flues are separated by a longitudinal partition, which has the effect of forming a hot-air or smoke chamber in the top front part of the stove. The orifices of the two branch flues extend partly over the back portion of the horizontal flues, so as to enable the products of combustion passing up through the mouth of the main aperture immediately over the fire to be carried up the branch flues with those products which pass off through the lateral gratings and flues. *Patent abandoned.*

437. D. TASSIN. *Improvements in preventing the explosion of steam boilers.* Dated February 17, 1863.

It is known that explosions usually occur when the steam engines are at rest, and when the steam may be said to be at a mean pressure in the boilers—that is to say, when the stone float can sway or move freely at the least bubbling of the water. The patentee states that he has ascertained that it is elasticity which causes the explosion of steam boilers. The stone float of a steam boiler has through its centre an iron clasp suspended on a copper wire; when the water contained in a boiler happens to be more or less impregnated with acid or alkali, the least movement which takes place in the float causes a shock or friction between the two different metals (iron and copper) that are in contact, and the electric spark is produced at their point of junction, and thence comes the explosion. This invention consists in preventing these electric sparks, and, consequently the explosions of steam boilers by electricity in the following manner:—In place of employing two metals to the stone float, he only uses one metal both for the clasp and for the suspending of the float, for which reason the clasp, as well as the wire which suspends or sustains the stone float, he makes of copper, and by using only one metal the same will not be capable of emitting electric sparks under the circumstances above mentioned, and electric explosions will be thus prevented. *Patent completed.*

438. E. STRAWSON. *Improvements in the manufacture of buttons, which may be instantaneously attached without sewing.* Dated February 18, 1863.

This invention consists in forming a button in the shell form; a small hole is made in the face near the edge, and a large one in the centre of the back; a curvilinear pin is passed through the hole in the face, and takes hold of the material to which it is to be attached through the hole in the back, and is then forced into the inside of the button, which can be turned round on it, and so make it perfectly secure. Another mode is to have a hole stamped in the back of the button, the edges of which are turned inwards, and the fastening is formed of a piece of wire in the shape of a staple with harpoon points, which is forced through the cloth, and into the hole in the button, which compresses the points till they have passed the inverted edge, when they immediately expand from their own elasticity, and form a secure fastening, allowing the button to revolve. Another mode is to have a hole stamped in the back of the button, the edges of which are turned inwards, and the fastening to which is formed of a piece of bent wire, with the ends turned down or terminating in harpoon points, which is first forced through the cloth, and then into the hole in the back of the button, when the ends hook over the edge of the flange, and are perfectly secure, at the same time allowing the button to revolve. To attach buttons to leather garments, a ring of leather is doubled together; two holes are made in the material to which it is to be attached, through which it is then passed; then both ends of the ring are put through a hole in the back of the button, which can be made smaller if necessary, and a pin is then put through them, which secures them, and also allows the button to revolve. *Patent completed.*

439. G. H. GEYELIN. *An improved grate, whereby the perfect combustion of the various compounds of coal is produced.* Dated February 18, 1863.

This invention consists of a revolving grate with a single or double central partition, through which air is supplied to the fire and gases; one-half of the grate is covered in by a fixed plate. Whenever fresh coals are added to the front fire, the grate is made to revolve on its pivot, so as to bring the fresh coals under the fixed plate, where they are distilled, and the carburetted hydrogen gas (smoke) disengaged, which ignites in passing over the front fire. *Patent abandoned.*

440. M. SIEGRIST. *An improved atmospheric brake or break.* Dated February 18, 1863.

This invention consists in rendering rarified air or vacuum available as a brake power. *Patent abandoned.*

441. J. BARKER and E. MOSS. *Improvements in portable and stationary crabs or cranes.* Dated February 18, 1863.

This invention consists in placing the barrel and gearing and also the shafts and framework of a crab or crane upon a platform resting upon a circular conical support, fixed to a bed or foundation plate, so that the barrel and parts connected with it can be readily turned in any direction, without shifting the base, and afterwards held fast by a central bolt and nut. This part of the invention applies to both portable and stationary crabs and cranes; but when they are portable only, the inventors form slots in the base or foundation plate for holding a number of bars on each side, which can be drawn out for supporting weights when the crab or crane is in use, and pushed in when no additional weight is required. In both portable and stationary crabs or cranes, they make the brake-wheel of a V-shape instead of flat. *Patent abandoned.*

442. J. F. SPENCER. *Improvements in apparatus for regulating and working the valves of steam and other engines.* Dated February 18, 1863.

These improvements apply only to those cases where the valve or valves for regulating the admission or suppression of the steam is separate and distinct from the exhausting valve. In engines that have to be reversed the patentee attaches two distinct links placed side by side and connected together so as to form a double link to two eccentric rods worked by eccentrics on the crank or other shaft, so that one eccentric rod is attached to one end of the double link, and the other to the other end of the double link. The radius or connecting rod that is attached at one end to the exhaust valve or its rod or lever is attached at the other end to a sliding link in, say link 1 of the double link, and the radius or connecting rod that is attached at one end to the expansion or steam slide or its rod or lever is attached at the other end to a block sliding in, say, link 2 of the double link. If the eccentrics are set as usual—one for head and the other for back gear—and the double link is suspended in one position by moving the radius rod in link 1, the exhaust valves can be reversed, and by moving the other radius rod in link 2, the steam valves can be reversed, and the expansion can be varied without in any way affecting the efficiency or action of the exhausting valves. In stationary engines, or engines that do not require to be reversed, he uses two eccentrics and rods, and only one single link, and attaches the exhaust valve rod to one end of the link, the steam or expansion valve rod only sliding on the link to vary the cut-off. *Patent completed.*

443. J. H. BLY. *Improvements in cooking stoves.* Dated February 18, 1863.

This invention is not fully described apart from the drawings. *Patent completed.*

444. F. JOHSTON and R. HEATLEY. *Certain improvements in looms for weaving.* Dated February 18, 1863.

This invention is designed to dispense with the tappets and shaft now employed to actuate the healds, and the improvements consists in a novel arrangement and combination of apparatus by which the rise and fall of the healds are to be obtained, and which may be thus described:—Upon the inside surface of the front bottom or cross rail of the loom a bracket or support is fixed, carrying a pulley attached to a toothed pinion; this pulley is situated immediately under the healds, and the heald strap passes from one heald round the pulley to the other heald. Upon the back rail of the loom a lever or bar has its fulcrum or centre of radiation, the opposite end of such lever being toothed in the form of a quadrant, which gears into the aforesaid pinion. This lever is caused to move to and fro laterally by means of an undulating disc, and thus causes the semirotation of the pinion and pulley, and produces the rocking motion wich causes the rise and fall of the healds. A second part of the invention relates to the regulation of the tension of the warp, and consists in the employment and use of a rod or carrier to support the warp, which is supported by vertical rods, each terminating in a bowl or roller fitting into two hollows or cups formed on the aforesaid oscillating lever, so that, as the lever moves to and fro, the bowl rises out of one hollow and drops into the other, and then returns; thus, when the warp is slack, the elevation between the hollows causes its tension, and when the "shed" is open and less tension is required, the carrier or rod is at the lowest point; a bar is also employed upon the warp to give tension instead of the ordinary warp beam weights. *Patent abandoned.*

445. J. PLATT and W. RICHARDSON. *Improvements in machinery or apparatus for cleaning cotton from seeds.* Dated February 18, 1863.

This invention relates to that machinery for cleaning cotton from seeds known as the Macarthy gin, and has for its object the prevention of accidental breaking of the reciprocating blade or blades should they become clogged by an accumulation of material or otherwise unduly resisted. For this purpose, the inventors drive the said blade or blades through the medium of friction surfaces which will yield under the above-mentioned circumstances. Thus they mount a pulley loosely upon a shaft, which pulley is pressed forward by a spring, so as to cause it to force a disc of leather against a boss fast upon the said shaft, which also carries the cranks by which the blade or blades are caused to perform the reciprocating motion. The pulley above mentioned they use for driving the roller of the gin. When, therefore, an obstruction occurs, the friction surfaces will slip, and the action of the blade or blades will cease although the roller continue to revolve. *Patent abandoned.*

446. G. T. BOUSFIELD. *Improvements in breech-loading fire-arms.* Dated February 18, 1863.

This invention is not described apart from the drawings. *Patent completed.*

447. F. J. REED. *Improvements in apparatus for traversing guns.* (A communication.) Dated February 18, 1863.

This invention is carried out as follows:—Directly under the left rail of the chasses, and near the rear transom, is a shaft called the upper horizontal shaft; it is attached by and turns in two boxes or bearings affixed to the under surface of the left hand rail near the rear transom. Upon this shaft, directly outside of the rail, is a pinion, and upon the outer end of the shaft there is a cranked handle. Upon the outer and lower edge of the rear transom, directly under the the left hand rail, is a horizontal counter-shaft. This shaft is secured by two boxes or bearings to the rear transom. Upon the outer end of this shaft, and driven by the pinion before mentioned, is a cog wheel, and on the inner end of the shaft is a bevelled pinion which drives a large bevelled cog-wheel on an upright shaft, which turns in boxes or bearings fixed to the rear transom. Upon the lower end of the upright shaft is fixed a pinion which works into a circular toothed rack. *Patent completed.*

448. G. T. BOUSFIELD. *Improvements in the manufacture of boots and shoes, and in preparing india rubber for such and other uses.* (A communication.) Dated February 18, 1863.

The patentee claims—1, a leather boot or shoe having a vulcanized india-rubber sole sewed on in the manner described; 2, a leather boot or shoe having a vulcanized india-rubber sole secured with nails driven in from the outside and clenched; 3, a leather boot or shoes having a sole of vulcanized india rubber secured by wooden pegs driven through the sole, the upper leather, and the inner sole, as described; 4, a vulcanized india-rubber sole having a groove for the purpose described; 5, a vulcanized india-rubber counter or heel stiffener made as described; 6, the process described of preparing india-rubber rags so that they may be employed in the manufacture of soles for boots and shoes and other articles as described. *Patent completed.*

449. J. PUNTIS. *Improved appliances for displaying in the open air or indoors illuminated designs, devices, mottoes, or announcements, and in which jets of gas are employed as the illuminating agent.* Dated February 18, 1863.

This invention consists of an air-tight metal chamber of any shape, into which gas is admitted. This chamber is perforated with very fine holes on one or both sides, as occasion may require, and in any device or configuration for the purpose of illumination, and on the gas being admitted into the said chamber, the gas will pass through the said perforations, and when ignited the outside or perforated side or both sides, as the case may be, will clearly display the design. Outside the above-mentioned chamber the design or device can be painted in japan or distemper colours, or ornamented in any manner to suit the design of illumination, as circumstances may require or as fancy may dictate. *Patent completed.*

450. J. GRAY and J. HUDSON. *Improvements in the treatment of steatite, and in its application to certain purposes.* Dated February 18, 1863.

In carrying out this invention, the inventors take steatite, as extracted from its natural bed, and reduce it into pieces of small size, or by stamping or grinding disintegrate it and leave it in the condition of coarse powder. It is then put on to the hearth of a reverberatory furnace, and subjected to the action of heat. By this means the discolouration that is due to the presence of oxide of iron and other foreign matters is removed, and the material may be more or less bleached according to the duration of the process, and is then ready for subsequent use. They employ steatite thus prepared as a substitute for white lead in the manufacture of paints and such like articles of commerce. White steatite colours may be thus produced, and any variations of shade between white and brown may be obtained. *Patent abandoned.*

451. R. P. ROBERTS. *Improved axle-boxes for carriages or vehicles.* (A communication.) Dated February 19, 1863.

This invention consists in the method of securing the box in the hub or nave, which is accomplished by the use of a conical or wedge-shaped nut on the end of the box, which, when screwed up, operates both to wedge and clamp the box in the hub or nave. *Patent abandoned.*

452. T. MARKLAND and J. C. DICKINSON. *Certain improvements in machinery or apparatus for warping or beaming yarns and threads.* Dated February 19, 1863.

This invention is designed for the purpose of stopping the mechanism employed in the processes of warping and beaming when any of the threads become disunited; and the improvements consist in a novel adaptation, arrangement, and construction of apparatus for effecting the said purpose, and which may be described as follows:—Between the ordinary collars and warping beam a series of dents is arranged and secured in elastic material, so as to be contracted or expanded at requirement. These dents are employed to serve as guides for fingers or levers under which the yarn passes from the rollers to the beam, the said yarn on its progress passing underneath a cranked or bent portion of the said levers or yard guides, thus keeping them by the tension of the yarn in an elevated position; but as soon as one or more of the yarn threads become broken or disconnected, the levers or yarn guides resting upon such threads are released, and fall upon the frame holding the fulcra or centres of such levers and guides, thereby preventing or stopping a reciprocating rod in connection with the stopping motion of the machine from completing its action, causing an instantaneous stoppage to the whole machine. A faller shaft having a wire attached to a bell-crank lever passes underneath the whole series of guides, which, when the machine is stopped, raises such guides into position for the warp or yarn passing under them in their progress to the warping mill. *Patent completed.*

453. W. SHERWOOD. *An improvement or improvements in wine-glasses.* Dated February 19, 1863.

This invention consists in making wine-glasses by attaching bowls of glass to stems and feet made of metal. At the base of the bowl a peg or short stem of glass is formed, which is fixed in a screw socket by plaster of Paris or other cement. A foot and stem made of metal are connected with the bowl by means of a hollow screw on the top of the stem, into which the screw socket at the base of the bowl screws. *Patent abandoned.*

454. L. A. POUGET. *Improvements in the manufacture of oil lamps.* Dated February 19, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

455. R. PINKNEY. *Improvements in the manufacture of metallic pens.* Dated February 19, 1863.

This invention consists in the manufacture of pens, as substitutes for the ordinary steel and gold pens, of aluminium bronze. One of such alloys, of about 5 per cent. of aluminium to 95 of copper, possesses a fine gold colour. Another alloy, of 7½ per cent. of copper, possesses a greenish cold colour; and a third of such alloys consists of about 10 per cent. of aluminium to 90 per cent. of copper. *Patent abandoned.*

456. J. J. BADART. *Improvements in the preparation of cotton seed-cake.* Dated February 19, 1863.

Cakes of cotton-seed, obtained when pressing out the oil from cotton-seed, are now used for feeding cattle, but the cakes, after a few weeks, rapidly deteriorate on account of the cakes "heating." According to this invention, the patentee subjects the cakes, after they come from the press, to heat for some time, in order to dry them thoroughly; the cakes may then be stored and kept for a considerable time without any deterioration of their original fattening powers. He prefers to dry the cakes by placing them in a rack in a drying chamber heated to about 180 degs. Fahr. *Patent completed.*

457. W. TRUSTRUM. *Improvements in the manufacture of oiled silk.* Dated February 19, 1863.

The silk, after having been coated with oil in the usual manner is, according to this invention, finished by coating it with a solution of shellac, which the patentee prepares by dissolving the gum in water containing a little ammonia. He employs the following proportions:—3 lbs. of shellac, 1 gallon of water, and ½ lb. of ammonia. The solution of shellac is applied in a very diluted state, and several times, otherwise the film of shellac which the solution leaves on evaporating would not be of uniform thickness. *Patent completed.*

458. N. THOMPSON. *Improvements in apparatus for stopping bottles, jars, and other vessels, and in tools for producing parts of such apparatus.* Dated February 19, 1863.

This invention has reference to a previous patent, dated November 18, 1862, No. 3,100. According to this invention for stopping bottles and jars and other vessels, the neck of the vessel is made with a groove around it a short distance below the mouth, and the stopping apparatus (no part of which is permanently attached to the vessel) consists of a ring of sheet metal, with flanges projecting inwards from its upper and lower edges. This ring is divided into two parts, each of a semicircular form, which are hinged together on one side. To the upper flange of one of the half rings, a circular plate of the same diameter as the interior of the ring is soldered or attached, and in the centre of this plate is a hole, and immediately below it a screw nut is fixed; this receives a short screw, to the lower end of which a plate is connected in such a manner that the screw can turn independently of the plate. A disc or packing of cork or similar material is attached to the plate, and the top of the screw is made with a recess to receive a key by which it may be turned. When the stopping apparatus is placed on the neck of the vessel, and the two half-rings closed together, the flange at the lower edge of the ring enters the groove in the neck of the vessel all round at the same time; the plate at the lower end of the screw comes immediately over the mouth of the vessel, and the upper flange of the part of the ring which is not attached to the top plate comes over the edge of the plate so as to hold it down to the neck of the vessel; then, by turning the screw, the plate at its lower end with the packing upon it is forced down on to the top of the neck, and so closes fluid-tight the mouth of the vessel. *Patent completed.*

459. H. B. BARLOW. *Certain improvements in weaving, and in the machinery employed therein.* (A communication.) Dated February 20, 1863.

This invention is not described apart from the drawings. *Patent completed.*

460. W. MARSDEN. *Improvements in envelopes.* Dated February 20, 1863.

In carrying out this invention, the inventor forms spring locks of any suitable metal by means of dies and pressure, and folding and overlapping the same so that the slot is just above the recess in the front part of the lock to allow the tongue of the seal portion to pass into it with ease and facility, and occasionally through the lower portion thereof. *Patent abandoned.*

461. W. MARSDEN. *Improvements in buttons and other similar fastenings, and in the modes of attaching or securing the same.* Dated February 20, 1863.

This invention relates in part to certain improvements in the formation of buttons and other similar articles, whereby the same are rendered self-attaching, and in part to improvements in the media for fastening the ordinary buttons of commerce, and the like, to, in, or upon materials, to be thereby held together whether for wearing

apparel or other purposes. The object of the said invention in both cases is to dispense with the present tedious, constantly failing, and insecure mode or process of sewing on, by the substitution of an instantaneous, perfectly secure, and permanent fastening media, by which the buttons, &c., when once attached, will not come off, unless purposely removed, but can be also instantaneously detached when required. The said improvements consist, in the first place, in forming the said buttons, &c., with the shanks or tangs and other attaching media of the forms described integrally therewith; and in the second place in making the said attaching media apart from the said buttons, &c., and applying the same therewith, and also in adapting the same to buttons and other fastenings of the ordinary or other forms. *Patent completed.*

462. C. Billingsley. *Improvements in saddlery, harness, driving straps, and similar articles.* Dated February 20, 1863.

This invention relates to an improved fastener, intended as a substitute for the ordinary buckle. When a stirrup has to be suspended to a strap, band, or belt, the strap, band, or belt has at the end where it is to be fastened a number of holes for lengthening or shortening, and near the part where it is required to be fastened there is a clip of of leather or metal, and also a metal plate having one or more fixed or moveable studs projecting from it; the perforated end is passed through or round the stirrup, and then passed through the clip, and one or more of the holes are passed over the stud or studs on the fixed metal plate, a loop of leather being provided for retaining the end of the strap in its proper position. *Patent completed.*

463. J. Bentley and H. Booth. *Improvements in looms for weaving.* Dated February 20, 1863.

In the improved treading motion, each heald is attached to a jack or lever above and below in the usual way, but the patentees give motion to the jacks and healds in the following manner:—Each of the jacks at the opposite end to where it is attached to the heald is connected by a cord or wire to a T-shaped lever working on a stationary shaft or stud, and to each lever is jointed three other levers, one at the middle and one at each end. To the middle lever is fixed a bracket acted upon by a pattern chain; and the ends of the bracket, and also the end of the middle lever, are in contact with the other two levers, so that when the middle lever rises up and down, according to the pattern chain, it shall act upon the other two levers, and raise them up and down in order to bring one or the other in contact with a slide. When the top lever is acted upon by the slide, it gives one movement to the head, and when the bottom lever is acted upon the other movement is given to the heald, and the healds are brought back to close the shed by studs or rods fixed to the slide. *Patent completed.*

464. C. W. Siemens. *Improvements in insulating and supporting telegraph line wires.* Dated February 20, 1863.

The patentee claims—1, The employment of the juice or milk of the india-rubber and gutta-percha trees and varieties of the same for coating electric telegraph line wires or cables. 2, Effecting one or more coats of india rubber or gutta percha, either alternately or combined, upon electric line wires, by passing the wire to be so coated successively through a bath containing the juice or juices of the india-rubber and gutta-percha trees, and a shaft containing heated air or gases to consolidate or indurate the covering. Also the combination of such successive coats with layers or coats of insulating material applied in any known manner. 3, Effecting a tenacious covering to insulated telegraph line wire by saturating the fibrous material employed in forming the same with the juice or milk of the india-rubber or gutta-percha trees in the manner described. 4, The construction and use of posts or supports to electric telegraph line wires composed of a foundation plate of cast or wrought iron, or equivalent for the same, to which is attached by bolts or otherwise a pipe or socket of cast or wrought iron rising to some height above the ground, and receiving in its upper end a conical or cylindrical welded wrought-iron tube cemented into the same, and carrying the insulating supports for the line wire, substantially as described. 5, The construction of insulating supports for suspending the line wire or line wires from posts, as described. *Patent completed.*

465. W. Hainsworth. *Improvements in the manufacture of cast-iron pipes, columns, or any description of tubing.* Dated February 20, 1863.

This invention consists in forming the core bar solid or hollow of wrought or cast metal, or other suitable material, and of such a form in the cross section as to adapt it by being surrounded by green sand to form the core (thus dispensing with a baked core), and in combining with such core bar a core box in three or more parts, so that in making the core it is accessible the whole length. The core bar is provided with lugs in order to retain the green sand when rammed between them. The two top parts and bottom part of the core box are respectively formed so as to give the required curvature to the sand, one part of the box being left open, and the corresponding part of the curvature of the sand being produced by means of a "strickle" worked by hand. Air-holes are formed in the sand by means of bars or rods fixed in it and then withdrawn. *Patent abandoned.*

466. R. Bell. *Improvements in armour-plating or protecting ships and vessels.* Dated February 20, 1863.

This invention consists in securing to the iron frames or ribs double surface plates, that is, plates somewhat similar in form to ordinary rails for railways, the web or beam connecting the two surfaces being of a depth varying with the requirements of the ship. The inner surface of the plates is recessed, so as to receive between every two plates an intermediate and smaller but similarly shaped double-surfaced and webbed strengthening plate. Between every two plates where they are brought together on the outer surface, the patentee fits a rib or filling-up piece of teak or other suitable material, and for the purpose of tightening all the plates he makes an aperture through the web of all of them, and introduces in such aperture, in a heated state, a bolt or bolts so as to run vertically. He then passes a key through the bottom of the bolt, which, on cooling, tightens all the plates, and gives stability to the whole structure. He beds the inner surface of the plates on tarred felt or other like suitable material. In some cases he surrounds the vertical tie-bolt with a wooden washer or collar. At intervals he passes iron collars or clips, which run at right angles or nearly so to the vertical tie-bolts, round the vertical bolts, and keys the clips to the inner side of the frames or ribs of the vessel. *Patent completed.*

467. W. Clark. *An improvement in boilers for disintegrating and pulping vegetable substances.* (A communication.) Dated February 20, 1863.

The principal object of this improvement is to ensure the complete submergence of the substances in the liquor or solution during the boiling process; and to this end the boiler is made of an upright form, with a man-hole and man-head at the top, and with a perforated diaphragm or screen having a man-hole in its centre, corresponding with the first-mentioned man-hole, and communicating therewith by means of a perforated cylinder or well, and fitted with another man-head. The vegetable substances are confined below the diaphragm or screen, and the liquor or solution allowed to rise above it, thereby ensuring the submergence of the said substances. *Patent completed.*

468. W. Clark. *Improvements in projectiles for ordnance.* (A communication.) Dated February 20, 1863.

This invention relates to what are technically known as sub-calibre shot and shell, that is to say, shot and shell of a calibre less than that of the guns from which they are intended to be fired, and consists—1, in the combination of a bolt or elongated shell of iron or steel having a cutting face and a surrounding casing of wood or other light material; 2, in a rear cap of metal so applied in combination with the bolt or shell of the wooden casing as to serve as a means of holding the wooden casing, attaching the packing device, and guiding the rear end of the projectile in the bore of the gun; 3, in a front cap of metal so applied in combination with the bolt or shell and the wooden casing as to serve the purposes of holding the forward end of the said casing, of supporting and guiding the front end of the said casing in the bore of the gun, and of effecting the explosion of the charge of the shell by resistance against the surface of the body penetrated by the shell itself. *Patent completed.*

469. F. W. Bendorf. *Improvements in governors or apparatus for regulating the speed of steam engines or other engines for driving machinery.* Dated February 20, 1863.

For the purposes of this invention, the inventor employs a vibrating arm or instrument kept in motion by the steam or other engine, so that the number of vibrations of the arm or instrument corresponds with the number of revolutions of the engine. Together with this arm or instrument a pendulum is employed; it is of such a length as to swing in unison therewith when the engine is running at the speed required, whilst the vibrating arm or instrument and the pendulum are in unison. The throttle valve of the engine (or other apparatus serving a similar purpose) is not acted on; but directly the vibrating arm or instrument gets either in advance of or behind the pendulum, catches, previously held out of action by the pendulum, are allowed to act, and these cause the vibrating arm or instrument to drive the rod of the throttle valve or similar apparatus in one or other direction, according as it is required to make the engine go a ster or slower. *Patent abandoned.*

470. W. Husband and J. Quick. *Improvements in apparatus for raising sewage and water.* Dated February 20 1863.

This invention consists of improved apparatus for the purpose of raising the sewage and water from one level to another in pipes, and for securing a continuous flow of sewage and water along a tube or pipe, the apparatus effecting these objects with all the advantages of a pump, and yet requiring no valves. The inventor proposes to apply the apparatus to the elbow of a tube or pipe of a curve representing the segment of a circle of any required radius, the tube forming a portion of the said apparatus and being cut with a slot in its interior pheriphery in order to permit of the passage of the arms or spokes of a wheel or of a disc within such slot. He proposes to set a wheel or a disc upon an axle which works in bearings or journals fixed on standards, the centre of the axle being concentric with that of the segmental tube; the arms of the wheel are, or the disc is, of such diameter as to enter the tube by passing within the slot, and the said arms are, or the disc is, provided with pistons packed or otherwise to fit the interior of the tube. There may be any desired number of pistons attached according to the dimensions of the apparatus. Power is applied to cause the wheel or disc to rotate, and the slot is packed with an elastic packing to close together immediately after the passage of the arms (when a wheel is used) or to press on each side of the disc (when a disc is used); or it is packed with strips of leather or other material, closing on the disc by the pressure of water within the tube. *Patent abandoned.*

471. C. Malpas. *Improvements in ovens or kilns for firing, burning, or baking pottery, bricks, tiles, and other earthenware or ceramic articles.* Dated February 21, 1863.

The patentee claims—1, The construction and employment of annular ovens or kilns, with revolving beds for baking, burning, or firing pottery ware and earthern or ceramic articles, having one or more external furnaces; and diametrically opposite these, or at some distance from the same, one or more openings for filling in and removing the goods to be fired, and in which ovens or kilns the draught from the furnace or furnaces passes directly underneath the objects to be fired, and thence vertically up among the same into one or more flues formed over or near the roof of the oven or kiln. Also, in combination with the above, the arrangement of flues lining a certain portion or the walls of the oven or kiln for gradually raising the temperature of the articles to be fired before they reach the furnaces, substantially as set forth. 2, The construction and employment of a chamber serving as a mustering, drying, and placing room, formed on the top of annular ovens or kilns with rotating beds, so as to utilize the spare heat therefrom. 3, The patentee claims, in combination, the arrangement of the several parts of annular ovens or kilns with rotating beds, as described. *Patent completed.*

472. R. Thompson. *Improvements in apparatus for moulding.* Dated February 21, 1863.

This invention is particularly applicable for moulding socket pipes to be cast on end with the socket downwards, but it may be applied in moulding other articles. When the invention is applied in moulding socket pipes of large dimensions, the core barrel is made in two parts, connected by a taper joint, the larger diameter for the interior of the socket being attached to or cast with the body of the truck usually employed for facilitating the transport of the mould into and out of the drying stove. The moulding box is or may be made in two parts; the lower portion containing the socket is connected to the truck and to the plain portion for the body of the pipe by studs and pins. The large portion of the core is made by means of a strickle board, and the remainder of the core is made in the usual manner. In moulding the pipe, the larger portion of the pattern is fixed to a separate truck, and the sand is rammed into the lower portion of the box; a short cylinder as now customary is employed for moulding the remainder of the pipe. *Patent abandoned.*

473. H. Kilshaw and T. Elce. *Certain improvements in machinery for preparing and doubling cotton and other fibrous substances.* Dated February 21, 1863.

This invention is not described apart from the drawings. *Patent completed.*

474. F. J. Manceaux. *Improvements in firearms, or in transforming arms of large calibre into arms of smaller calibre.* Dated February 21, 1863.

This invention consists, as hereafter set forth, in means of transforming small arms of large calibre, and muzzle-loading, into arms of smaller or reduced calibre, and either muzzle or breech-loading, preserving all the parts used in the first manufacture of the gun without any other change than that of the barrel. The patentee first cuts out bars or strips of walnut or other wood, similar to that of the stock of the arm in which a barrel of smaller calibre is to be substituted for the original and larger barrel, and rounds, shapes, and adjusts them in the channel or groove in the stock for the reception of the barrel of reduced calibre, so that they may exactly fill the place or channel occupied by the original barrel. He gently heats the fore part of the stock and the wood filling piece or pieces separately, and applies hot clear glue to the surfaces of both. He then adjusts the filling piece or pieces in the channel, and keeps them in close contact by bands wound round them by clasps or otherwise, and dries the glue under gentle heat. When thoroughly set, he cuts out of, or in, the filling a channel for the reception of a barrel of less calibre than that removed. He then heats to redness thereduced calibre barrel, and adjusts it in the channel so that it may bear on the bottom thereof, and so that the nipple on the new barrel may present itself directly under the head of the hammer of the lock. He then passes the breech screw through the tail of the barrel, and into the stock. The buckles and rings used for fastening the old barrel in the stock may be used for the barrel of smaller calibre; but in order to adapt them to this barrel he lines them with iron to make up for the difference in the calibre. To complete the adaptation of all the accessories of the larger to the smaller barrel, he lines the socket of the bayonet with iron or steel; and instead of the barrel of the smaller calibre being muzzle-loading, it may be breech-loading, in which case the channel will have to be carried further back in the stock. *Patent completed.*

475. E. T. Hughes. *Improvements in the treatment of colouring matters derived from tar for the purpose of making them applicable for painting.* (A communication.) Dated February 21, 1863.

For obtaining cakes of red, blue, and violet, the inventor takes 15 grammes of white soap, and dissolves it in 100 grammes of hot water, and then mixes with the solution 6 decigrammes of colour previously dissolved in methylitic alcohol, or other solvent. To this mixture he adds 25 grammes of pure alumina in a gelatinous state, and then filters and dries the mixture. These proportions may be varied at discretion; for instead of 6 decigrammes of colour, a large quantity may be used in order to have a greater depth of colour. Instead of the white soap, glycerine and soaps made from oils or grease derived from animal matters may be employed; and instead of the alumina, sulphate of barytes or other metallic or earthy oxide may be used, and thus obtain the means of manufacturing all the colours derived from tar into cakes or pigments. Thus, the colour is dissolved in any of the known solvents, and then mixed in a water bath with vegetable or animal soaps dissolved in the hot or cold state, and precipitating the colour by alumina previously precipitated from alum or sulphate of barytes, or any other kind or salt or metallic or earthy oxide. By these means, and especially by the assistance of an animal matter in a soapy state, the colours are rendered solid and durable, and are applicable for painting. *Patent completed.*

476. R. V. Dodwell. *An improved method of preventing the destruction of plants by insects and certain descriptions of animals, and in the means for effecting the same.* Dated February 21, 1863.

This invention consists in the application, adaptation, or employment of galvanic or electrical influence or agency for the destruction of insects, &c. The plants to be protected are to be surrounded by a galvanic arrangement of metals, either separately if large, or, if the plants are small, the bed containing them is to be surrounded, say, for instance, with an edging or border of zinc having a band of copper soldered or attached upon its surface, whereby a galvanic action is set up, and which will be found to effectually prevent the passage of insects or animals, for, though the action may be but slight, it excites in a sufficient degree to prevent them crossing it. Galvanic com-

binations of other metals may be employed. *Patent abandoned.*

477. A. H. Remond. *Improvements in preserving provisions, and in the apparatus employed for such purpose.* Dated February 21, 1863.

The first part of this invention consists in causing a current of electric fluid to pass through the cases containing the provisions after they are finally closed up; such electric fluid being made to pass along a fine iron or other metallic wire through the case, causes the wire to become red-hot and consume the oxygen. Another improvement consists in placing inside the case, and in connection with the thin wire, any known chemical agent (such as common sulphur, for instance) which, in its ordinary state, has no particular affinity for oxygen, but which, upon becoming ignited (by means of the electric wire above referred to) evolves any gas (sulphuric acid gas, for instance) which will absorb, destroy, or convert into a harmless gas the oxygen which is contained in the case, and which it is desired to get rid of; or the sulphur or other agent may be ignited by any other convenient means. A further improvement is as follows:—After the can has been closed, a sufficient quantity of hydrogen gas is to be introduced therein to form (with the oxygen which may be in the case) an explosive mixture or gas, and this gas is to be then ignited by passing a current of electricity along a metal wire through the same, and thus all traces of oxygen will be destroyed. *Patent abandoned.*

478. A. Ceileur. *Improvements in apparatus for taking photographic impressions or likenesses by means of the camera.* Dated February 21, 1863.

This apparatus consists of an arrangement of parts for holding the negative plate in camera obscuras, while taking the impression thereon by means of the lens, in such manner that the plate can be moved laterally and also vertically for the purpose of changing its position and presenting a new surface to receive an impression. *Patent abandoned.*

479. W. Wood. *Improvements in the process of manufacturing pomfret or liquorice cakes, rolls, sticks, and pipes, and other similar articles of confectionery.* Dated February 21, 1863.

We cannot here give space to the details of this invention. *Patent completed.*

480. H. Mackinder. *Improvements in apparatus for separating potatoes into different sizes.* Dated February 21, 1863.

The potatoes which are to be sorted into different sizes are placed in a hopper, from which they descend on to an inclined riddle. The parallel wires or rods of which this riddle is formed are set at such a distance apart as to allow only the smallest potatoes and the dirt to drop through. After passing over this riddle, the potatoes reach a second riddle of similar construction, but with the parallel wires or rods further apart, so as to allow potatoes suitable for seed to pass. These two riddles are combined together in a moveable frame carried by small wheels which rest upon short guide rails on the main frame of the apparatus, and the riddle frame receives a to-and-fro motion from a connecting rod and a crank on an axis which is driven by a band passing around a pulley on the crank axis, and also around another pulley which is driven directly by a crank handle. A fly-wheel is employed to render the motion more regular. The motion thus communicated to the riddles serves both to keep the potatoes in movement, and also to clear from the spaces of the screen any potatoes which may be set fast between them. There are for this purpose, immediately underneath the riddles, rollers passing from one side to the other of the fixed frame. These rollers are able to turn freely, but in other respects they are held stationary, and the riddles pass backwards and forwards over them, so that whenever a potato passes partly through the riddle, and then becomes fast, it is pushed back again by coming against one of the rollers, and thus the riddles are kept clear. *Patent completed.*

481. J. Brown. *Improvements in the manufacture of armour-plates for ships and other structures.* (A communication.) Dated February 21, 1863.

For the purposes of this invention, plates of wrought iron are piled one on the other having between them crushed or pulverized Franklinite Spiegal iron or similar metal. This pile is heated to a suitable degree to cause the Franklinite Spiegel iron or other metal to assume a pasty or melted state, and the wrought-iron plates to be brought to about a welding heat, so that, when rolled or pressed, the parts of the pile will combine. The rolling is to be continued till the mass is reduced into a plate of any desired thickness. A series of such compound plates are piled one on the other with pulverized Franklinite Spiegel iron or other like metal between them, and this pile is to be heated and rolled or pressed and reduced to the desired thickness either for an armour-plate or for being again piled with other plates as above explained. Fluxes may be used when found desirable. *Patent completed.*

482. A. Dugdale. *Improvements in throttle valves.* Dated February 21, 1863.

The patentee claims mounting and causing the valves to turn upon a shaft independent of the actuating parts, these latter being connected inside the steam-pipe by jointed rods, toothed sectors, or other mechanical equivalents, connected to one extremity of the valve, so that the shaft shall serve merely as a hinge or pivot for the valve. *Patent completed.*

483. W. E. Newton. *Improvements in the construction of wind instruments of music.* (A communication.) Dated February 21, 1863.

This invention relates principally to that kind of wind instrument in which valves or pistons are employed for modifying or assisting in producing the notes or tones. One of the objects of the invention is to facilitate a change of key, and another is to construct the instrument in such a manner that it can be carried more easily by the player. In order to effect the first object, the instrument is divided into two main parts, which are connected together by a central pivot on which one part may be turned horizontally on the other in either direction for a short distance. The upper part of the instrument carries the principal working parts, and the lower part consists mainly of the lower bends of the main tubes. In order to admit of changing the key of the instrument, there are several additional tubes, so that the main tube may be lengthened or shortened as may be desired. These additional tubes all terminate at the central part of the instrument, where the top and bottom parts are connected. These tubes are adapted to a perforated valve-plate, in which there are as many ways as there are sections of the main tubes in the lower half of the instrument. This valve-plate, with the tubes thereon, turns on the central pivot, so as to bring any section of the lower part of the main tube into coincidence with the upper part. A change of key may therefore be produced by simply moving the valve-plate round horizontally part of a circle. In order to render the instrument more convenient to carry, the bell part of the main tube is bent back, and passed either over the left shoulder or under the arm-pit. *Patent abandoned.*

485. W. H. Gauntlett. *Improvements in apparatus for heating the blast in the manufacture of iron.* Dated February 23, 1863.

This invention has for its object the more effectually heating the pipes before passing into the blast furnace in the smelting of iron ores, and is applicable either with the ordinary fuel, or with the waste gases generated in the furnaces. The patentee constructs a double stove with internal pipes having a division wall separating it into two single and distinct stoves, each having a separate fire grate or combustion chamber. There is an aperture in the division wall which is opened or closed by any convenient means. He makes the heating pipes with portions of their substance to project from the internal surface, or the internal surface may be corrugated. He also puts studs across the interior of the pipes from side to side. These projections, studs, or corrugated surfaces will have the effect of splitting up or disturbing the blast, and preventing it from passing through the the pipes in a body, and will consequently cause the heat to be more intimately conveyed to the air which it is intended to heat. He prefers to place a pair of these stoves opposite each tuyere house of the furnace, so as to deliver the blast direct or nearly so to the tuyeres. The two outlet pipes form a pair of stoves, having previously been allowed to converge into one pipe, by preference outside such pair of stoves. *Patent completed.*

486. E. T. Hughes. *Improvements in the process of cleaning organic matter.* (A communication.) Dated February 23, 1863.

This invention consists in the treatment of organic matter, more particularly wool and other fibrous materials charged with fatty and oleaginous or resinous substances, whereby the inventor separates the said fatty, oleaginous, or resinous substances from such fibrous or other matter. For this purpose, he places the organic matter in a vessel, where it may be subjected to pressure, and then forces through it, by means of a pump, or by hydrostatic pressure, a current of bisulphuret of carbon, or other volatile hydro-carbons, which dissolve the greasy substances and carry them off with it into a separate receiver, where, by means of heat, he separates the one from the other, and, subsequently, in order to free the organic matter from the volatile oil which may have been absorbed in the mass, he causes it to be traversed by a current of heated air put in motion by a force-pump or ordinary fan. *Patent abandoned.*

487. J. Eckersley. *Improvements in spinning and doubling silk.* Dated February 23, 1863.

This invention has for its object the spinning and doubling of the threads of the silk-worm direct from the cocoons. To accomplish this, the inventor prepares the cocoons in the ordinary manner, and then places them in a vessel or vessels containing hot water, the said water being maintained at or near a constant temperature by the aid of steam. The thread or threads of the cocoon or cocoons are passed over a hook or through an eye, and then pass between two rollers, and over the top roller and round a pin and between the said rollers again, but in an opposite direction to that before named. The thread now passes to an ordinary flyer, and it is wound on a bobbin placed on a spindle driven by a band or cord. The amount of twist is regulated by the velocity of the top roller, as compared with the velocity of the spindle. A traversing rail is used for traversing threads upon the bobbins. The object of spinning, as herein given, is to produce a more uniform thread with less labour than at present in use. The process known as doubling is accomplished by placing the threads of two or more of the before-named bobbins in such a position that they may pass through the eye or over the hook before named, and be spun or twisted together in a similar manner to that before named, and wound on other bobbins placed on the before-named spindles from which the first-named bobbins have been removed. *Patent abandoned.*

488. R. A. Brooman. *Improvements in dressing millstones, in ornamenting or engraving on glass, pottery, and other similar substances, and in materials employed therein.* (A communication.) Dated February 23, 1863.

This invention consists in dressing millstones, and in ornamenting glass, pottery, and other similar substances, by the action of hydro-fluoric acid on the silicious matter of which they are more or less composed. *Patent completed.*

489. J. B. E. Daticht. *Improvements in steam-engines.* Dated February 23, 1863.

This invention consists in utilizing the steam after it has produced its effect in the cylinders of steam-engines by passing it into and through condensing apparatus consisting of tubes surrounded by water alone, air alone, or by air and water, the air being forced in by a fan or blast, and the water, when water is used, being allowed to trickle down the outside of the tubes in a case surrounding the same, which water rises, overflows, and enters a double casing, escapes therefrom, and is returned to the supply cistern. The steam being more or less condensed, is forced by suitable pumps into the boiler directly, or through a coil in or round the casing of the boiler, whereby it becomes heated before entering the boiler. The condensers consist of jacketed cylinders containing within them another casing in which are tubes, into which tubes the waste steam from the cylinders is made to enter; or the patentee reverses the position of the steam and of the air and water, or air or water—that is to say, he causes the air and water, or air alone, or water alone, to pass through tubes contained in a casing or cylinder into which the steam to be condensed is admitted. *Patent completed.*

490. J. D. and A. P. Welch. *Improvements in machinery for blocking and pressing hats and bonnets.* Dated February 23, 1863.

This invention is not described apart from the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated May 8, 1863.

1158. C. F. Bielefeld. Improvements in the manufacture of sheets, slabs, and other articles where fibrous materials are employed.

Dated August 14, 1863.

2007. A. E. Brae, Leeds. Improved means of conducting electric currents through railway trains, and of actuating signals or alarums therein.

Dated August 15, 1863.

2023. E. Scott, engineer. Certain improvements in apparatus for governing or regulating the speed of engines. (A communication.)

Dated August 20, 1863.

2065. G. Spencer, 6, Cannon-street West, civil engineer. Improved solutions to be used in the manufacture of paints and the preservation of wood, stone, and metallic surfaces, and in the preservation and waterproofing of fibrous materials generally, and for other purposes. (A communication.)

2068. W. Hamilton, 45, Ship-street, Brighton, upholsterer. Improvements in the manufacture of spring mattresses.

Dated August 21, 1863.

2076. T. F. Cashin, civil engineer, Sheffield. Improved means of communication between the passengers, guard, and driver of a railway train in motion.

Dated August 25, 1863.

2101. W. E. Gedge, 11, Wellington-street, Strand. Improvements in machinery or apparatus to be used in the manufacture of handles. (A communication.)

Dated August 27, 1863.

2115. T. Bourne, New York. Improved method of storing and holding petroleum and other oils, naphtha, and other products of distillation containing essential oils. (A communication.)

2116. F. Pragst, Moscow and Manchester, engineer. Certain improvements in steam engines and in the mode of utilizing steam.

2117. J. Clark, Glasgow. Certain improvements in break blocks for railway and other carriages, and in the means of applying the same.

Dated August 28, 1863.

2123. R. Bell, Glasgow, manufacturer. Improved measuring apparatus for looms.

2125. E. Vickers, Sheffield, manufacturer. Improvements in the manufacture of steel.

2129. C. Harratt, Hornsey-lane, Highgate. Improvements in apparatus for tilling land.

Dated August 29, 1863.

2131. H. C. Pennell, Weybridge, Surrey, gentleman. Improvements in the construction of skates.

2132. H. W. Putnam, New York, manufacturer. Improved machine for wringing clothes.

2133. G. Lowry, Stanley Steel Works, Salford, machine maker. Improvements in, and applicable to, cotton gins.

2135. W. Tingey, Manchester. Improvements in printing carpets, piled fabrics, druggets, and other similar articles.

2136. T. Williams, Manchester, cotton spinner. Improvements in machinery or apparatus for steaming and opening cotton and other fibrous materials.

2139. A. Agnew, Welshpool, Montgomery, gunmaker. Improvements in breech-loading firearms.

2141. W. Weldon, 3, Falcon-court, Fleet-street, publisher. Improvements in apparatus for aërial navigation.

2143. J. Dodge, Waterford, Saratoga, New York, mechanical engineer. Improvements in machinery or apparatus for grinding and polishing metallic articles.

Dated August 31, 1863.

2147. F. A. Braendlin, Birmingham, mechanical engineer. Improvements in breech-loading firearms.

2149. B. L. Burnett, Teignmouth, wine merchant. Improved arrangements for removing the fuel from stoves or grates, and for facilitating the extinguishing of the fires used therein.

2153. J. Miles, Hastings, Sussex, cutler. Improvements in traps for catching rats and mice, rabbits, and other animals and birds.

2155. M. J. Roberts, Pendarron-house, near Crickhowell, esquire. Improvements in the arrangements or fitting of axles for railway and other carriages.

Dated September 1, 1863.

2156. J. Snider, jun., Dorset-street, merchant. Improvements in breech-loading and other ordnance, part of which is applicable to the utilizing of old smooth-bore cannon, and in projectiles to be used therewith.

2157. C. Shorrock, manufacturer, and W. Shorrock, manager, Over Darwen. Certain improvements in looms for weaving.

2158. G. Russell, Glasgow, engineer. Improvements in apparatus for cooking, and for obtaining fresh water for use on shipboard and otherwise.

2159. W. Clark, 53, Chancery-lane, engineer. Improvements in hydraulic apparatus. (A communication.)

2163. T. Erich, 77, Newgate-street. Improvements in machinery for pressing peat. (A communication.)

Dated September 3, 1863.

2176. W. Boulton, iron founder, and J. Worthington, engineer, Burslem. An improved method of making and inlaying encaustic tiles or other plastic articles and substances.

2178. W. and T. Jolliffe, steamboat owners, W. Graham, ship's joiner, and H. Taylor, ship's joiner, Liverpool. Improvements applicable to paddle and other propelling wheels, for navigable vessels.

2182. J. Loebl and I. Pick, Scott's-yard, Bush-lane, merchants. Improvements in fastening gloves.

Dated September 4, 1863.

2186. T. Fisher, 7, Remington-street, City-road. Improvements in spring balances where spiral springs are used.

2188. G. Hargreaves, Shipley, Bradford, York, worsted spinner and manufacturer. Improvements in steam boilers.

Dated September 5, 1863.

2190. W. Norton, Holley Bank, near Arva, Cavan, gentleman. Improvements in laying and supporting submarine telegraph cables.

2194. R. Batt, Waterhouse Mill, Milnthorpe, Westmoreland, paper manufacturer. Improvements in paper-making machinery.

2196. G. B. Rennie, Holland-street, Blackfriars, engineer. Improvements in the construction of floating docks and pontoons, and the means of cleaning, painting, or repairing them.

Dated September 7, 1863.

2200. H. Twelvetrees, Bromley, manufacturer. Improvements in portable mangling and wringing apparatus.

2202. S. Gerish, 60, Shoe-lane, Holborn, and J. Weston, 80, Whitecross-street, St. Luke's. Improvements in machinery for mortising, drilling, dovetailing, and cutting wood, and in tools to be used for mortising.

Dated September 8, 1863.

2204. J. H. Cutler, Birmingham, manufacturer. A new or improved dress fastening, which said fastening is also applicable to the fastening of bands and belts and to other like purposes.

2206. W. A. Wilson, Liverpool, engineer, and J. Smith, Liverpool, baker. Improvements in furnace firegrates.

2210. W. Hewitt, Bristol, engineer. An improved rudder, and means of working the same.

Dated September 9, 1863.

2216. T. Naden, Birmingham, architect. Improvements in raising the covers or lids of hot water jugs, tea-pots, coffee-pots, and other vessels.

2220. E. T. Hughes, 123, Chancery-lane. Improvements in the manufacture of chenille, and in the machinery or apparatus employed therein. (A communication.)

2222. W. Clark, 53, Chancery-lane, engineer. Improvements in the means of utilizing refuse azoted matters of commerce for the manufacture of various chemical products. (A communication.)

2224. G. T. Bousfield, Loughborough-park, Brixton. Improvements in rollers to be used in machinery for spinning and manufacturing wool, cotton, and other fibrous materials. (A communication.)

2226. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improvement in steam engines. (A communication.)

2228. E. Olliver, engineer, and G. Myers, draughtsman. Improvements in apparatus for lowering and disengaging boats from vessels.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, September 22, 1863.

1158. C. F. Bielefeld. Manufacture of sheets, slabs, and other articles when fibrous materials are employed.

1173. C. H. G. Williams. Manufacture of colouring matters.

1178. R. Burgess. Marking, etching, or engraving cylindrical and other surfaces.

1183. R. A. Brooman. Coupling and disconnecting carriages on railways. (A communication.)

1184. J. S. Guirette. Inhaling apparatus.

1186. J. E. McConnell and G. H. Bovill. Chains for cables.

1191. J. E. McConnell and G. H. Bovill. Treating worn-out railway tyres.

1193. G. A. Huddart. Cutting slate.

1195. R. A. Brooman. Spring mattresses. (A communication.)

1199. R. A. Brooman. Laying submarine telegraph cables. (A communication.)

1201. T. Parkinson and F. Taylor. Weaving, sizing, dressing, and dyeing.

1203. J. E. McConnell and G. H. Bovill. Manufacture of thick plates of wrought iron for armour plates and other purposes.

1206. B. Lambert. Paper-makers' rag or pulp engines.

1208. J. Farmer. Calendering, embossing, and other such machines used for finishing woven fabrics.

1209. R. A. Brooman. Extraction of hydro-carburets from minerals. (A communication.)

1219. I. Parker. Connecting and securing door and other knobs or handles to their spindles.

1222. D. M. Fyfe. Raising, removing, transporting, and refixing military or other targets or mantlets.

1225. R. T. Mallet. Construction of piers, walls, and other similar structures.

1228. J. Patterson. Grinding, crushing, cleaning, and hulling or shelling various kinds of farm or vegetable produce.

1230. J. Hinks. Lamps.

1235. J. Gibbs. Preparing and spinning flax and other vegetable fibres and filaments.

1241. W. Watson. Manufacture of bread.

1245. R. Fenner and W. H. Hight. Envelope folding machines.

1250. J. Edwards. Permanent way.

1258. T. P. Salt. Manufacture of trusses.

1301. R. A. Brooman. Indicating the position of trains upon railways. (A communication.)

1337. C. T. Boutet. Measuring distances and altitudes.

1362. W. Clark. Manufacture of manure. (A communication.)

1365. W. Clark. Apparatus for printing fabrics, papers, and other surfaces in colours. (A communication.)

1782. H. Elliott. Breech-loading firearms.

1836. C. Beslay. Making all woven and thready fabrics waterproof, and in finishing or surfacing fabrics generally. (A communication.)

1975. E. Myers and H. Forbes. Rotary pump.

2044. J. Broadley. Means or apparatus employed in weaving.

2108. T. Westhorp. Preparing out rope strands or yarns for carding into oakum.

2128. J. Alison. Tilling land.

2132. H. W. Putnam. Wringing clothes.

2138. D. Spiers, A. Boyd, and J. Kirkwood. Looms for weaving.

2226. A. V. Newton. Steam engines. (A communication.)

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed September 18, 1863.

735. E. Lever.
736. H. Wilde.
740. C. Webster and W. Forgie.
745. J. and T. A. Nield.
746. R. A. Brooman.
750. C. Pryse and D. Kirkwood.
752. F. de Wylde.
754. F. and A. Roberts.
756. G. A. Biddell.
757. E. Hartley, T. and J. Mellodew.
758. J. M. Hetherington.
764. W. Johnston.
769. J. Reilly and W. Martin.
780. G. Stuart.
781. C. Monson.
782. R. Armitage and C. Senior.
793. R. A. Brooman.
787. L. Christofleau.
789. G. Cowdery.
792. W. Johnson.
801. J. Grantham.
802. W. M. Morgan.
804. J. Taylor.
811. J. Leeming and R. S. Markindale.
816. J. Musgrave.
818. R. Mushet.
821. W. E. Newton.
839. W. Clark.
848. D. S. Sutherland.
884. J. Mosheimer.
905. G. Colomb.
952. A. V. Newton.
1010. W. E. Newton.
1040. A. Legras.
1064. W. Clark.
1223. W. Clark.
1262. J. Coignard.
1339. C. E. Laederich.
1616. W. B. and J. Bradshaw.
1619. G. Davies.
1693. W. Basford.
1738. A. Moutleart and W. Tent.
1828. J. E. Vanner.
1844. G. Davies.
1862. W. Tranter.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2243. J. Horsey.
2249. S. Barnwell and A. Rollason.
2257. G. F. Smith.
2260. W. E. Newton.
2264. H. Stead and H. Gledhill.
2271. G. Owen.
2282. T. Greenwood.
2290. V. H. Laurent.
2292. J. and J. Cash.
2295. T. Westhorp.
2298. R. Mushet.
2306. H. E. Skinner and W. H. Miller.
2326. J. Haworth.
2365. R. Mushet.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2159. S. Chodzko.
2202. W. Young.
2294. J. Holman.
2251. J. J. Russell and J. B. Howell.

MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 2, 1868.

STEAM PLOUGHING.

Notwithstanding a very considerable expenditure of capital by men of talent and experience, steam cultivation makes but slow progress. In certain cases, horses have been sold, fences removed, roads constructed, and fields levelled, to make way for the steam plough; and from the farms where this course has been adopted, the most favourable reports are constantly laid before the public. A few hundred instances of the kind, however, really prove very little; and the practical introduction of the steam plough as an habitual implement with our farmers, is undoubtedly still very far off. This is the more remarkable, inasmuch as steam cultivation is not a thing of yesterday. The requisite machinery has been brought so near the limit of perfection, that the work accomplished by it, on heavy soils especially, is all that the farmer can desire; while its management may be safely entrusted, after a little preparatory training, to such men as may be met with in every agricultural district in Great Britain. Steam tillage benefits the land, enables larger crops of better quality to be grown, and renders the agriculturist, to a certain extent, independent of the vicissitudes of the weather in spring and autumn. As far as the quality of the work done is a criterion of excellence, that performed by steam is pronounced the best possible, almost without a dissentient voice. Yet steam ploughing makes slow progress into favour with the English farmer, simply because these valuable results have been hitherto obtained under exceptional circumstances, only to be secured under conditions which agriculturists, as a body, are not prepared to meet. In other words, the situations in which the steam plough can be employed with success are exceptional, because a very considerable outlay is absolutely required to prepare most farms for its employment. An analysis of most of the reports published, will show that very large rectangular fields, and good roads traversing the farms, are the distinguishing features of those districts where steam has proved most successful as a cultivator. The horse can work anywhere with advantage; steam cannot; and without suitable preparation its employment must end in loss and disappointment. The Duke of Sutherland, in company with many others who have capital at command, have expressly prepared hundreds of acres for his majesty Steam. On these lands, the anchor—always troublesome and unwieldy—is no longer needed; stout posts, fixed 30 yards apart along the headlands, supplying the necessary support for a chain and snatch-block which take the place of the anchor. As a rule, however, our English farms are picturesquely broken up by intervening hedge-rows, into fields much too small to be economically tilled by the steam plough under its present form; and there is every reason to donbt that an early removal of these fences will leave a fair opening for the supersedal of horse labour by steam.

The English farmer usually spends his capital freely, once he is convinced that he spends it to advantage; and we do not conceive that the price of a 12-horse engine and set of tackle, say £850, retards the introduction of ploughing apparatus in any material degree. Machinery, if good, costs money, and a good article is always worthy of a fair price. But, unfortunately, the class of machinery which is employed to till our land, is exposed to such peculiar and unforeseen risks that "breakdowns" are of constant occurrence. The actual value of a share or skyfe may be very trifling; but the stoppage of the entire apparatus until it is replaced, is a very considerable item of expenditure; and when we reflect that in certain soils the delays from this cause alone, have been sufficient to reduce the average diurnal work to three acres, for weeks together, we can understand the objection which a farmer may have, to the introduction of steam as a substitute for the trusty horses, which accomplished their task with clockwork regularity. Things are better now perhaps than they were, in this respect; but we recollect an instance, not many years ago, when a cart left the foundry every morning with a load of shares, returning in the evening, with those broken during the day by a very good set of machinery, ploughing a common in Staffordshire. In very heavy soils, a competent authority tells us, that "a stone the size of a man's fist will break a share." We never yet have heard any valid objection urged against the use of wrought iron and steel shares in such cases: if one did not exist, we presume they would have superseded those of cast iron long since. Unfortunately, breakages are not confined to shares; ropes, anchors, windlasses, and engines being exposed to almost equal risks. No one who has not had actual experience in the construction and working of machinery of this kind, can form an idea of the trials to which it is put. Much depends on attention to little matters of constructive detail, on which the fate of a week's work may depend.

It is to be hoped that the experience of the next few years will so far advance the science of steam cultivation, that delays from the breakage of tackle, may be almost wholly obviated. We feel very confident that such will be the case. Breakages, however, bad as they are, are not the sole obstacle to the perfection of the steam plough. The weight and size of a 12-horse engine is frequently quite sufficient to exclude it from many farms which could be cultivated with advantage by lighter though not less powerful machinery. If fitted as a self-propeller, with wide wheels and an under drum, its total length cannot be much short of 20 ft., while its breadth will render the uprooting of gate-posts necessary before it can enter most fields. If not a self-propeller, our crooked farm lanes afford little scope for the exercise of the capabilities of a team sufficiently powerful to draw it to its destination through a foot or so of November mud. From many reasons we are disposed to look with favour on Mr. Collinson Hall's system of working two 6-horse engines in combination. The division of the weight effected by this means is a most important advantage; while the first cost of the apparatus as a whole, the anchor being suppressed, cannot be much greater than that of one on the single-engine system. The difficulty of starting and stopping both engines simultaneously, is a considerable, but not, we imagine, an insurmountable objection, which may be overcome possibly by very simple means. Certain it is that a single engine much under 12-horse power, is of little avail for cultivating land on any system; yet, such an engine is far too powerful for any of the other operations required on a farm, such as thrashing, root-cutting, &c. Not one in twenty of our farmers possess a thrashing-machine of their own, preferring to hire one when occasion requires. The farmer who possesses a set of double-engine ploughing tackle can easily find employment for both engines, during the thrashing season, by purchasing a second machine. The supply of horses to remove the engine from farm to farm, is generally limited; and the transportation of a 12-horse engine several miles, over bad roads most probably, is a serious consideration, from its great weight.

We have said that farms to be tilled must be adapted, by a considerable outlay possibly, to the requirements of the machinery which is to work over it. The interests involved will, in all probability, postpone for years the universality of such an adaptation. Those interested in the progress of the steam plough should, meanwhile, exert themselves, as far as possible, to meet the present demands of the farmer, by producing machinery as flexible—so to speak—in its application as possible. The engineer is too apt to suppose that the farmer does not really know what he wants; such a conclusion is absurd. Our agriculturists, as a body, know very well how they require their land tilled; and so long as that is done for them with ease, regularity, and economy, they will not criticize the means by which the desirable end is obtained. Nothing discourages so much as constant breakages, however trifling; and we do not hesitate to assert that, but for them, steam ploughing would now hold a very different position from that which it does. The farmer requires reliable machinery, as well as the manufacturer, the steamship proprietor, or the railway company. That, once supplied, fences will be levelled, money expended, horses sold, and the steam plough take its proper place, as a worker of the soil, far more reliable than animal power.

STEAM HAMMERS, AND THE BEST FOUNDATIONS FOR THEM.

Since the discovery and introduction of the arts of puddling and rolling wrought iron, by the talented, but very ill-used Henry Cort, no invention connected with the forge has been fraught with more importance than that of the steam hammer. Its employment has led to vast and startling improvements in forging, and in smith's work of all descriptions. The steam hammer may, with truth, be said to have knocked down, and annihilated practical difficulties which only a quarter of a century ago were considered unconquerable. It has enabled the smith, and the machinist to achieve triumphs which were once unhoped for and apparently unattainable, whilst by lessening the cost of both heavy and light forgings it has stimulated the iron trade to a very material extent.

The steam hammer is a docile and invaluable servant; but, like human servants, it demands proper treatment in order to develop its full efficiency and usefulness. It may be perverted to the worst purposes, and be made productive of the worst results, if entrusted to careless or "unknowing hands." For example, if the workman in charge of such an apparatus attempts to obtain from its action too much at a single heat of the forging in hand, he will probably damage the latter to a very considerable extent. The iron will inevitably in such case be crushed, mutilated, and probably crystallized to such a degree as to be deprived of its best elements, and thus rendered totally unfit for the purpose to which it is to be devoted. Great judgment, skill, and a well-practised eye on the part of the steam-hammer manipulator, are essential to the making it productive of sound work.

It was objected to the steam hammer on its first introduction, that it would lead the forgeman or smith into perilous temptation. By its aid, it was said, he could readily cover defects in forgings, whether arising from overheating

or other causes. Like other merely theoretical objections to new inventions, this notion has been swept away by the practical use of the instrument, and a return from it to the hand hammer would be deemed as unwise as would be a relapse from the planing machine to the cold chisel. It has become a necessary concomitant to the forge, and improvements in its details and mode of action are alone to be hoped for or sought after. Its *principle* is fully established.

We have said that care is required in dealing with the steam hammer, and one of the primary points to be looked to is unquestionably the obtaining of the proper degree of heat in the forging upon which it is to act. Overheating especially is the bane of forged work. Vain will be all attempts to remedy this vital evil. The best qualities of the material will be eliminated by it, and the finished forging will be but "a mockery, a delusion," and perhaps "a snare." It will never be sound or tough, although in appearance it may be both. Of course it is necessary that the quality of the iron in the first instance be good—that is to say, there should be present in it the minimum quantity of foreign matter, as sulphur, scoria, or oxides of any kind. This desideratum will be best effected by the most scrupulous attention to the fuel used for heating the forgings. It is a well understood fact, that if coals be used in the forge furnace which are impregnated with sulphurous or other foreign and deleterious matter, the forging will imbibe the poisonous particles and become vitiated accordingly. Perhaps the Belside Hartley and the Hastings Hartley coal are the best known kinds for forging purposes. They at least are freest from extraneous bodies. Having obtained the desiderata of good iron and good fuel for heating it, the next consideration should be to use both properly. The fire-box should never be *filled* with fuel, whatever the character of the material; for if it be so, the forging will occupy a long time in becoming properly heated, and a scale or crust will be generated on its surface. The homœopathic, rather than the allopathic, system of furnace treatment is undoubtedly the best. A lazy furnaceman may practise the latter, but a judicious one will certainly administer small quantities of fuel at frequent intervals, and thus add materially to the chances of obtaining a good forging.

If this and other minor conditions be attended to, the iron, when duly heated, will present a semi-fluid or pasty appearance. In this state it is fit for welding, and no time should be lost in effecting that operation. When exposed to the air, oxidation, or scaling as the common term is, rapidly commences, and no amount of sand, however carefully applied by the smith, will prevent the fatal contingency. A very small portion of the cleanest and purest sand obtainable may vitrify on the surface of the forging, and thus protect it to some slight extent from oxidation, but careful heating and a prompt application of the steam hammer are the best means of ensuring a sound weld.

It is not requisite to dwell upon the fact that the fewer times a piece of smith's work is submitted to the fire the better, because few smiths are ignorant of it. It is a *sine-quâ-non* indeed to do as much at each heat as possible, and hence again the advantages of a quick eye and ready hand. It would be impossible to enumerate here the varieties of forgings, large and small, which may be and are economically and effectively produced by aid of the steam hammer. The interminable demands made upon the appliance in the establishment of an ordinary engineer, and the ready way in which they are responded to, prove it to be a veritable servant of all work, and literally a "true friend at a pinch." The class of smith-work in which the steam hammer is used to great advantage may be specified. It is that in which the welding on of swells or collars is the distinguishing feature. By hand labour this important branch of the smith's duty is always unsatisfactorily done. No dependence can be placed upon the work, however "cunning" the hand of the manipulator. The steam hammer, on the contrary, with the assistance of proper tools, properly handled, never fails to make "a good job" of such matters. The extensive use of blocks or dies in the shaping of small pieces of smiths'-work, and which tends to ensure sound and clean forgings, is due, almost entirely, to the steam hammer. It would be possible to add very lengthily to this list of valuable qualifications of the steam hammer, as an adjunct to both the peaceful, and the warlike sections of engineering—to do so, however, is superfluous. They are known and recognized by almost all practical men.

Let us turn our attention, rather, to the best means of fixing or seating the apparatus so as to ensure its stability and permanent usefulness. We have no hesitation in saying that, whatever the character of the soil may be, in the locality in which it is determined to place a steam hammer, the foundations for it should be composed of timber, the balks used ought not to be less than 10 in. or 15 in. square, and they should be from 20 ft. to 35 ft. long, according to the magnitude of the hammer. Framed together at right angles and bolted by rough spikes of iron, they should lie in at least six courses. The distance between the timbers must be left to the judgment of those to whom is confided the erection of the hammer, and depends somewhat on the nature of the sublying soil. The main object is to secure as large an area of surface foundation as circumstances will admit of. If this rule be attended to, there will be not only no subsidence after long working of the apparatus, but no tendency to that evil. The elastic nature of the timber courses will assuredly keep the bed of the hammer up to its original level, besides obviating the destructive jarring of the piston, &c., which sometimes manifests itself most disagreeably.

It may be said that timber so employed cannot last very long; but many instances might be adduced of its having remained sound for over twenty years; and we have little doubt that carefully-selected pine, in a dry soil, would not deteriorate very much in half a century. It must be admitted that the foundation of a steam hammer has a great and important task to perform. Besides sustaining the weight of the apparatus when in a state of rest, it may have to sustain six times that weight if the hammer be in operation—to say nothing of the alternating shocks resulting from each impact upon the forging. Concrete may be used if the bottom upon which the timbers rest be soft, but if it be so introduced, care must be taken to put in a stratum of sufficient thickness, or it will crack, and fail to perform its mission.

In some cases, it might not be improper to diminish the size of the timbers towards the surface of the ground. This would have the effect of concentrating, so to speak, the effect of the blows, and thus prevent an undue elasticity. The introduction of piles as foundations for steam hammers cannot, except in rare instances, be attended with practical good. Horizontal timbers, laid in courses, and covering a wide area, form, as we think, the best possible foundations for them. Thus provided, steam hammers will give out their powers most efficiently, their durability will be enhanced, and the cost of reparation will be minimized.

THE MONT CENIS TUNNEL.

The greatest obstacle which the civil engineer can by possibility encounter in the formation of a line of railway, is a great mountain-chain. Rivers, however wide, can be spanned in detail by a series of bridges springing from pier to pier; valleys, if too deep and wide to render the construction of an embankment desirable, can be traversed by viaducts on the same principles; mountains, however, permit the passage of a railway only under the conditions of a succession of steep inclines, or by the tedious and expensive process of tunnelling. Both means have been resorted to; and the elevated chains of both hemispheres afford us examples of the most magnificent engineering works which have ever been proposed or accomplished. In a recent number, we discussed at some length the means adopted for carrying the Great Indian Peninsular Railway across the Syahadree Hills, up the Bhore Ghaut. There we have an example of the incline system carried almost to its greatest limit. In the Mont Cenis Tunnel, we find nearly similar difficulties overcome on a totally different principle; while the magnitude of the works involved, and the means adopted for conducting them to a successful conclusion, render the undertaking one of the most remarkable in the history of engineering.

The Mont Cenis Tunnel is intended to connect Savoy with Piedmont; and in the district chosen for the future railway, the chain of the Alps extends about due east and west between two nearly parallel valleys. According to the plan which has been adopted, the northern entrance will be below Modane, about 18 miles west of Mont Cenis. On the south side the railway will emerge near the Alpine village of Bardonnèche, at a level considerably higher than the Modane entrance. Beyond the preliminary surveys required to lay out the line, nothing has yet been done towards the construction of the 25 miles of railway over an extremely difficult line of country, required to connect Bardonnèche with Susa; and we cannot consider the decision of deferring for the present the commencement of this portion of the line, as other than prudent, as it permits the concentration of the energies of all connected with the undertaking, on the vastly more important work of the tunnel. The greatest recommendation to the line from Bardonnèche to Modane, lies in the fact that it is much shorter than any other suggested for traversing the Alps between Savoy and Piedmon

The lowest pass of this chain on the Italian side is about 2,100 metres (a metre is 39.37 in., or a little over 3¼ feet) above the sea level; and the tunnel will enable the railway trains to cross the mountain at a height of about 1,333·8—*i.e.*, 766·2 metres below the present pass. Its southern opening at Bardonnèche, in the valley of Susa, is 1,335·38 metres above the sea level; from this point it rises 0.5 per 1,000 metres up to a distance of 6,100 metres—that is, to about the middle of the gallery, when it again slopes down at a declivity of 22.2 per 1,000 to its northern opening near Modane in Maurienne, which lies at a height of 1,202.82 metres above the sea: so that the actual difference of level between the two extremities is about 320 ft.; the Italian end being so much the highest. The steepest gradient within the tunnel equals about 1 in 45, rising to the middle from the French side, descending then towards the Italian extremity, at the rate of 1 in 2,000. One-half the tunnel thus having a stiff gradient, while the remainder is, practically speaking, a level.

When we consider that the total distance to be excavated through hard rock is about

miles, at such a depth that the iking of shafts is impossible, the mag-.ude of the difficulties to be surmounted iy be realized. Under the first idea, that inual labour alone, employed at each d was available; the termination of the ork could not be calculated on under twenty-e years; hence its promoters, reflecting on e vast annual outlay, necessarily extending er that period, so brought their influence to ar on the French Government, that they cceeded in procuring a convention—not, owever, until last year—with France, by the rtue of which the latter State undertook to iy the sum necessary for the construction of 110 metres of the tunnel—half its length— the rate of 3,000f. per metre, or 3,000,000f. r kilometre, on condition that this compen-ation should not, taken altogether, exceed ,000,000f., reckoning the work upon the nderstanding that it should be executed by rdinary means, and allowing a period of venty-five years as necessary for its comple-on; but they stipulated that, in the event of ie tunnel being accomplished in less than venty-five years, beginning with the 1st of anuary, 1862, the capital of 19,000,000f. vould be increased at the rate of 500,000f. for very entire year that might be deducted from he maximum of twenty-five years. If the vorks were to last less than fifteen years, the remium would be raised to 600,000f. for every ntire year's reduction; so that, if the work vere actually achieved in twelve and a-half vears, the Italians would gain a premium of nore than 16,000,000f. Moreover, as the French Government does not reimburse the Italians immediately, but pays the interest of the sums due, and these interests may be reckoned at 6,500,000f., France will, at the end of the work, be indebted to Italy to the amount of about 31,700,000f.

The tunnel was begun in 1857, with ordinary means. But that year and the two following were spent chiefly in preliminary operations, such as the construction of houses, workshops, &c., and up to the end of the year 1860 not much over 800 yards had been executed. The extremely slow progress of the works, by mere manual labour, stimulated the ingenuity of the engineers employed in their execution, MM. Grandis, Grattoni, and Sommeillier, who had already tried a boring machine designed by an English engineer, Mr. Bartlett, without success. Mr. Bartlett's contrivance was wrought by steam, and could not be applied to a tunnel where air could not be had for combustion. The Italian engineers proposed to substitute compressed air instead of steam; and, notwithstanding long opposition on the part of foreign scientific men, their method is now in full operation, and their success exceeds the most sanguine expectations. At the Bardonnèche end of the tunnel these gentlemen have availed themselves of a fall of water about 86 ft. high to force air to a pressure of about 90 lbs. on the square inch, within wrought-iron cylindrical egg-ended receivers.

The machinery employed for this purpose is extremely simple, the principle involved being very similar to that of the hydraulic ram. The compressed air, is conveyed from the receivers by a cast-iron main, about a foot in diameter, to the face of the working, where it puts the boring apparatus in action. This machine, nearly 8 ft. high and 10 ft. wide, occupies the drift-way, or heading, which precedes the finished tunnel, enlarged from the heading by manual labour. Eight or ten jumpers are put in motion by suitable pistons, reciprocating within cylinders, which admit of such a motion from time to time as will expose every portion of the rock face to the action of the jumpers. Varying with the hardness of the rock, the average time required by the machine for boring a hole 32 in. deep is rather less than an hour. As soon as about 80 holes have been bored into the rock the machine is disconnected from the main tube conveying the compressed air, and is then withdrawn on rails to a distance of 80 or 100 yards, behind massive wooden folding doors, designed to protect the machine and the workmen from the effects of the explosion. Miners then enter the gallery and charge the holes with powder, light the fuses, and then retire behind the doors, which are closed. After the explosion, another gang of workmen enter the gallery, and set to work to remove the rubbish in waggons running upon narrow rails laid beside the main track, and in about six hours the way is clear for the return of the machine with a fresh gang of workmen, when the same series of operations is commenced, the work being continued day and night with but rare and short intervals of repose. The rock is a metamorphic schist of variable composition, but apparently all belonging to the carboniferous series, for the most part extremely hard, and especially difficult to work in parts where it is traversed by veins of quartz, that very quickly destroy the steel points of the jumpers. Fortunately, the rock is so close that it effectually prevents the entrance of water in excess; no more having been hitherto encountered, than just suffices to keep the jumpers properly wet; the water being introduced into the holes in extremely fine jets under the action of the compressed air. The machine at the Modane face of the working is supplied with air by a regular pumping apparatus put in motion by a large wheel driven by the waters of the Arc, the torrent which was at first employed to drive a machine similar to that at the Bardonnèche end, frequently failing in its supply. The air, after putting the pistons in motion, by escaping within the tunnel serves to ventilate it in the most perfect manner. Gas is introduced at the sides of the working; good light and ample ventilation securing the comfort of the labourers, and consequently the rapid advance of the works. The total estimated quantity of rock to be excavated is 600,000 cubic metres, or about 784,666 cubic yards. As the tunnel is 13,354 yards long, this will give for the lineal yard forward, and for the whole face of the tunnel to be removed, nearly 58 cubic yards. At the average advance of 1·17 metre per day, which the engineers calculate on from the progress already made, this will give a daily removal of 73½ yards cube; and if both faces are worked at the same progressive rate, it will yield 147 cubic yards of daily excavation for the joint work of all the boring machines in operation, and at this rate of working it will require about 14¾ years to complete the excavation. Many particulars respecting the tunnel have been laid before the Italian Parliament by General Menabrea, Minister of Public Works, from which we select the following, which will give at least a good idea of the importance of the undertaking and the progress already made :—" In 1862, in order to pierce 380 metres of the side of Bardonnèche, the men were employed 582 times, each time 7 hrs. 39 min., for boring, and 6 hrs. 2 min. for loading and exploding the mines and clearing away the rubbish. In these 582 operations, 45,751 holes were bored, from 75 to 80 centimetres in depth; 72,538 chisels were set to work; there were 54,785 blasts, 18,622 kilogrammes of gunpowder were fired, 76,000 metres of match line were burnt, and 1,334,000 cubic metres of compressed air were consumed, equal to 8,004,000 cubic metres of atmospheric air. The workmen, on the 1st of January, 1863, were 720 at Modane, and 900 at Bardonnèche—altogether, 1,620. The grants for the work were as follows: For 1857, 1,000,000f.; for 1858, 3,500,000f.; for 1859, 500,000f.; for 1860, 2,500,000f.; for 1861, 3,000,000f.; for 1862, 2,000,000f; for 1863, 2,000,000f.; altogether, up to this day, 14,500,000f. The expense, up to the end of February, has risen to 13,182,603f. 18c., and the Minister has in hand 1,317,396f. 82c. He, therefore, thought that it would be necessary to apply to the Chamber for an additional grant of 500,000f., to enable him to finish 600 to 700 metres of tunnel, which were to be completed before the end of the present year."

THE WRECK REGISTER AND CHART FOR 1862.

This synopsis of the returns made by the Board of Trade to Parliament, of the wrecks and casualties which have taken place on the coasts, and in the seas, of the British Isles during the past year, is now before us.

Compared with previous years the register informs us that the wreck experience of the past year is very unfavourable. But the number of lives lost is fortunately considerably under the average, owing chiefly to the valuable and prompt services of life-boats and other means employed on occasions of wrecks on our coast. The wrecks and casualties in the year show a large increase on the average of those during the preceding eleven years. The number of wrecks in the last eleven years was 13,657, while the total voyages made to and from British ports in that period were 2,745,910—so that 1 ship was wrecked out of every 201. During the past year, as previously stated, the number of voyages of vessels to and from ports in the United Kingdom was 268,462, and out of this large number 1,827 casualties occurred—or 1 in every 147.

In the past eleven years, from the above wrecks 1,775 persons were lost, or nearly 800 each year. Last year, it appears from the returns that the lives of 4,729 persons were imperilled on the coasts of the British Isles, of which number 690, or 14·59 per cent. were lost. The wrecks and disasters for the year 1862 may be thus classed :—

	Vessels.
Totally wrecked	455
Seriously damaged	695
Totally lost in collision	66
Damaged seriously by collision.........	272
Injured by collision.........................	339
Total	1827

This number of disasters for last year is at the rate of five per day; the months of January, February, March, October, November, and December being the most destructive to ships.

Amidst the desolating scenes which the Wreck Register and Chart reveal, it is consolatory to know that by means of life-boats, the life-preserving apparatus, ships' own boats, and other means, 20,150 lives have been saved from a watery grave during the past seven years, of which 4,039 were rescued last year.

The following is a summary of the means used in saving the 4,039 lives from wrecks on the coasts of the United Kingdom during the past year :—

By life-boats and rocket and mortar apparatus	637
By ships, ships' own boats, shore boats, steamers, &c......................	3389
By individual exertion....................	13
Total	4039

Schooners and brigs were, as usual, the most numerous description of vessels that were lost during the past year on our shores. These are usually employed in our coasting and coal trade, and the destruction of hundreds of them even in moderate gales, is now reduced to a matter of certainty.

In December last seven vessels foundered off the east coast of England—with the loss of all hands —while engaged in coasting voyages. One of them was a collier sloop 71 years of age! Another collier brig also foundered in October last, and 7 out of 9 of her crew were drowned. She was 99 years old!

It also remarked that in perfectly calm weather, **23 vessels were wrecked**; in light airs, 28; in light **breezes**, 56; in gentle breezes, 43; in moderate breezes, 110; in fresh breezes, 187; in strong breezes, 195; in moderate gales, 75; in fresh gales, 170; in strong gales, 199; in whole gales, 218; in storms, 63; in hurricanes, 69; and in unknown and variable weather, 52.

It is a lamentable fact, in regard to collisions, that 141 took place in fine and clear weather; the whole number of collisions during the year being 338—102 in the day-time and 236 in the night. Last year 11 collisions occurred between steamers, and 190 between sailing-vessels, while both were under way. 32 collisions also took place between sailing-vessels, one being at anchor and another under way at the time; but no collisions occurred between steamers under these circumstances. 46 collisions likewise took place between steamers and sailing-vessels, both being under way; and 6 only when sailing-vessels at anchor were run into by steamers. 53 collisions also occurred by vessels breaking from their anchors or moorings. We earnestly trust that the admirable regulations which the Board of Trade have just published to prevent collisions at sea will materially tend to lessen the number of these fearful disasters.

The most disastrous wrecks, with the greatest loss of life, occur between that part of the coast extending from Skerries and Lambay to Fair Head and Mull of Kantyre. During the past thirteen years 1,641 lives were lost in that district. The next is from the North Foreland to St. Katherine's Point, which during the same period claims 1,136 lives.

The estimated loss of property involved in the destruction of a portion only of the vessels wrecked in the last six years amounted to four-and-a-half millions of pounds sterling, although the total amount, being unreported, cannot be ascertained; but who can appreciate the value of the precious lives lost in those terrible disasters, except those at our seaports and fishing villages who are now widows and orphans or friendless who have bewailed with unutterable anguish the loss of a husband, father, or near relation?

On the other hand, it is most gratifying to find that in these six years 4,169 lives were rescued from the jaws of death by life-boats and the life-saving apparatus *alone*. It may be proper to observe that these means of saving life are rarely used except under the most perilous of circumstances.

It may be interesting here to recapitulate briefly the operations of the National Life-boat Institution, which has now 125 life-boats under its management. During the past year, in addition to saving twenty-one vessels from destruction, 358 lives were rescued by the life-boats of the society. For these services rewards amounting to £915 18s. 1d. were voted. The number of lives saved by the life-boats of the society, or by special exertions, for which it has granted rewards since its formation, is 13,220. For these services 82 gold medals, 733 silver medals, and £17,200 in cash have been granted as rewards. The institution has also expended £75,380 on life-boats, life-boat transporting carriages, and boat-houses. Surely a society which has thus been productive of the greatest services in the cause of humanity, will not have to appeal in vain to the public for help to enable it to continue its merciful work on our dangerous sea-board! We may add that contributions in aid of the great and important work of the National Life-boat Institution are received by all the bankers throughout the United Kingdom, and by the Secretary, at the Institution, 14, John-street, Adelphi, London.

THE APPLICATION OF PHOTOGRAPHY TO MINING.

WHEN St. Victor first made his experiments in the application of light to senitized surfaces, and, aided by Daguerre, worked out the great problem which they were both endeavouring to solve, he little thought what an immense advantage would arise to the world at large from his making a practical thing of the action of light upon metallic oxides.

The casual observer, as he passes the numerous groups of photographic pictures which meet his gaze in almost every street, looks upon the art as something that panders to the vanity of the multitude, or tends to keep alive the bonds of memory. Even the most practical men, those who are engaged in the development of the resources of the country, in their hasty conclusions, deem the work of the photographer, is but an idle occupation, and of no actual benefit save to the operator himself.

But while the astronomer takes pictures of the sun, moon, and stars; while the mechanic obtains views of his machinery, so perfect in perspective, so accurate in proportion and detail, that thay may serve as working plans; and while the architect produces admirable representations of the buildings he constructs, all, with the camera, the mining engineer also does in many instances avail himself of the same method to illustrate the advances he has made in his labours, and to show the grounds upon which he is working.

It is seldom that the Board of Directors ever visit the mine; the stockholders themselves rarely travel thitherward; and all the information which they gain of the progress of the work, or the character the country at the mine, is derived from the terse and sententious reports of the manager. Did the manager understand the use of the camera, a knowledge which is very easily acquired, he could show from actual views, the progress made in his work, weekly or monthly, as might be desired. He could present pictures of the mine and its surroundings, show the bearings of the outcrop, the trend of the vein, the features of the adjoining country, and, in fact, each and every minutia that would aid greatly in satisfying the Board of the correctness of his system, and in familiarizing them with the property whose interests are entrusted to his guidance. When the construction of the buildings or the erection of machinery is progressing, a few minutes' work with the camera, at the close of each week, will show the exact stage of the advance made since the last view was taken. So much wall has been built, so much machinery has been put into position, so much excavation has been made, and the quick action of the camera has told the story more plainly, more truthfully, than a volume of words could do.

Much of the value of the vein can be forshadowed by the physical features of the country in which it is situated. If easily accessible, even a low grade of ores could be worked profitably, while those which might be very rich would, from the expenditure necessarily entailed upon them, by the difficulties of their position, never be remunerative. Here the camera becomes useful in its correct delineations of the surface, showing to those who reside at a distance from the mine the actual position of the vien and the facilities of approaching it. It is true that an absolute necessity does not exist for these features of the mine to be presented to the notice of the Board; but it cannot be doubted that the more fully they understand their property, the better they will be able to manage it. It is not possible for all to visit the mine, and by actual inspection, and examination, make themselves conversant with all the local details of it; but they can avail themselves of the aid of this branch of science, and bring as it were, the mine to their own offices or firesides and inspect it at their leisure. Those who have seen the views which have been taken, from time to time, by the different artists of this State of various mining localities, can readily understand how greatly such delineations must aid in a correct estimate of the value of such properties by those who cannot visit them in person. Nor is it necessary to be encumbered with costly or heavy and clumsy apparatus; a light and portable camera, with the stand upon which to place it—so light, that both can be carried with ease by sustaining their weight upon two fingers of the hand—with lenses that can be readily carried in the ve pocket, can readily be obtained at any of the photographic ware-rooms. The writer of this article has a complete apparatus, which is packed in a box about one foot square, containing the camera, glasses for pictures, lenses, and the requsite chemicals; the whole of which does not weigh over a dozen pounds. And often in journeying through mining districts he has stopped his mule, taken a view, and in eight minutes been again upon his journey.

Such is the progress made in the art, that plates are now prepared which may be kept for years, if not exposed to the light, and then placed in the camera and a view taken upon them. This advancement in the art precludes the necessity of carrying bulky packages of bottles and chemicals, while travelling, to obtain good views, and thus places it in the power of any who are so disposed, to bring back with them picturesque delinations of the scenes through they have passed. It can be rendered practically useful by illustrating the progress of work upon the mines.—*San Francisco Mining and Scientific Press.*

STEAM PLOUGHS AT WORCESTER.

WE extract the following interesting Paper from the "Journal of the Royal Agricultural Society of England." It forms a portion of an essay entitled "Five Years' Progress of Steam Cultivation," by Mr. J. A. Clarke. Mr. Clarke writes as follows:—

In selecting proofs from the great mass of evidence which is cumulating every day, I may, first of all, take steam culture as represented in the trial fields at Worcester.

Some systems familiar to visitors of our "country meetings" have been abandoned. No such thing as a locomotive engine travelling over the land, yoked to one or more traction-implements, appeared at Worcester. And though a locomotive-engine, delving the soil by rotary spades, has been exhibited at the agricultural exposition of Lille, our English inventors have at present no real embodiment of wood and metal of the mechanical idea so philosophically and pictorially placed before us in the "Chronicles of a Clay Farm." Steam-tillage in 1868 consists in dragging a traction-implement with a wire rope (or a substitute for it), hauled either by a stationary motive-power, or a motive-power moveable along the headland.

Leaving out of view the so-called "traction" engines, or highway and farm-road locomotives, we find "entered" in the Worcester Catalogue the steam-culture machinery of thirteen different exhibitors.

Mr. Thomas Beards, of Stow, near Buckingham, showed a plough adapted for any system of haulage. A rectangular iron frame upon two furrow-wheels and two land wheels, carries at each end a lever-frame with two plough-bodies, for turning over two furrows at once; and the implement traverses backward and forward, without turning round at the ends of the field, the two sets of ploughs being alternately dropped into the ground or held aloft in the air by chains and a barrel upon the top of the frame. This is a modification of the "balance" or "equipoise" principle exhibited by Messrs. Fisken, at Carlisle, in 1855.

The implement of Mr. William Steevens, of Hammersmith, is also designed for any system of rope-traction. Two sets of ploughs pointing towards each other, are so hung within a main carriage-frame (with steerage-wheels) as to rise or fall with a parallel motion—the share-points and mould-board heels together; the bell-cranks and rods which effect this also balancing the two sets, in order that they may be easily lifted or lowered. A scale of inches upon the main frame marks the depth to which the ploughs are set, and the depth of the furrows can be instantaneously altered without stopping the implement. The plough-bodies can be removed from their respective frames and replaced by cultivating-tines; and, again, instead of these, a harrow, taking 10 to 15 ft. breadth at once, may be affixed below each of the rising and falling frames. There seems to be no reason why double-breasted or ridge-ploughs, or, indeed, almost any form of tillage tool, should not be added at will to the fundamental framing. Mr. Steevens has also produced an improved rope-porter, enabling the rope to be readily lifted off the roller while the plough is passing. The work accomplished by the implement (worked by Messrs. Howard's form of tackle manufactured by Messrs. Garrett) was certainly of good quality, though a breakage occurred from lack of strength for excessively hard operations.

Mr. J. A. Williams, of Baydon, Wilts, has directed much attention to combinations of implements for steam-power. One of his arrangements consists of a large field-roller, with one heavy drag-harrow before and another behind it, set in a rectangular frame, which is pulled backwards and forwards without turning. Two lighter harrows, hung, one at each end of the frame, are raised when preceding, but lowered into work when following, the heavy drags and roller. Another set of light harrows, or a chain-harrow, is attached at the side; the whole covering a breadth of 13 ft., but adapting the position of the several implements to all inequalities of surface. The steerage is effected by simply diverting the rope to one side or the other, more or less out of the line of draught. For reducing a roughly broken surface, at a large acreage per day, this is a [illegible] efficient and economical machine. Mr. Will[illegible] cultivator carries its tines in lever-bars, whic[illegible] and fall of their own accord, like the coulter[illegible] drill, taking 6 ft. width at once. For these [illegible] may be substituted three "double-tom" [illegible] ploughs, by which land is ridged for [illegible] laid up for winter exposure at a wonderf[illegible] rate. This implement is turned at the [illegible]

by the action of the ropes, passed round the fore part in bows, which also hold off the tail-rope in its proper place. The same practical exhibitor has also a land-presser for steam-power, so constructed that six wheels press as many furrows at once, each wheel riding independently of the rest.

Mr. C. Clay, of Wakefield, has a cultivator of peculiar action. The tines are fixed to cross-bars, which are at liberty to rotate part of a revolution; so that when the implement begins its journey, one-half the tines enter of their own accord into the ground, while the other half (pointing in an opposite direction) simultaneously rise out of work. Hence the workman has only the steering to manage. The implement runs upon a single pair of wheels.

The rotary rolling forker, which was a familiar object at the Society's meetings a few years ago, has reappeared in the modified form of a digging-machine, invented by Dr. G. Ager, of Aylsham, and exhibited by the manufacturers, Messrs. E. R. and F. Turner, of Ipswich. A set of rowels of large diameter, with curved tines or teeth, being set in motion by the onward progress of the implement, penetrate and lift up the soil; while a second and smaller set of rowels, driven by toothed wheels and pitch-chains from the former set, clears the teeth of earth, much as the revolving spurs of a Norwegian harrow clear each other. The machine is very similar to one which the Rev. S. Smith, of Lois Weedon, invented and worked with admirable effect a few years ago. The work produced by the present digger is reported by employers to be very effective and valuable, and to be performed with a comparatively small expenditure of motive power. The forked tilling part of the machine is placed in a circular frame, to which the hauling-ropes are attached, and is turned half-round upon friction rollers in this frame, for working in the opposite direction.

Among the articles designed to aid steam tillage, I must not omit a clever little contrivance of Mr. W. S. Underhill, of Newport, Salop. To prevent that serious delay—the breaking of a rope—and to preclude the risk of great damage from sudden obstructions, inattention to signals, &c., the rope is attached to the implement by a spring-hook—that is, a hook so made as to release itself from its hold when a spiral spring upon its shank becomes compressed beyond a certain point; and this yielding strain may be set to any number of cwts. at pleasure. The device is good, and the cost low; and the hook is adapted to any apparatus not fitted with "taking-up gear" upon the implement.

Coming now to distinct systems of haulage, I find entered in the Catalogue, but not present in the Show-yard, the apparatus of Mr. W. Fisken, of Stamfordham, Northumberland. The peculiarity in the invention (which has undergone great modifications since its early appearance in Scotland, in 1852, and its exhibition at Carlisle, in 1855), consists in conveying the power from a stationary engine by means of hemp-rope running at a high velocity. At first the windlass, with ploughs attached, worked its way to and fro by coiling or by gripping a fixed and immoveable wire-rope; then the implement was made to travel by means of a drum armed with cutting-blades that laid hold of the ground; and, lastly, this has been abandoned for the present plan of two self-moving anchor windlasses, one on each headland, alternately coiling a single wire-rope which pulls the plough,—the endless hemp cord mounted upon porters, along one headland and across the field alongside the furrow, transmitting power and motion to the two windlasses. The price of the apparatus is marked excessively low; but now that we have learned to carry wire-rope clear off the land, and thus to take power to almost unlimited distances with very little waste in friction, I do not perceive what special advantages could be gained by the present form of this invention.

The apparatus of Mr. W. Smith, of Woolston, Bletchley, Bucks, is so well known that a description would be superfluous; and only a few minor alterations appeared in the tackle at Worcester. The double cylinder 10-horse ordinary portable engine had an additional band-wheel, formed in one piece with the fly-wheel, giving a choice of two speeds for lighter or harder work. The stationary four-wheeled windlass, with a couple of coiling-drums; the claw anchors let into the ground by digging holes; and the simple, strong, light, three-tined and five-tined cultivators, turned round at the ends of the work by the action of the ropes, present no apparent novelty in construction. The pulleys or snatch-blocks, however (four, five, or even six in number, according to the shape of the field), have been made with a deeper and more durable centre-boss rotating upon a longer pin; and the rope-porters standing upon curved wood rockers cannot tumble over, and are easily moved. In addition to the two grubbers of different sizes, Mr. Smith showed his combined cultivator and corn-drill (with grubbing tines and seed-coulters on one lever frame), which has been much lightened, improved, and cheapened in price since last year. This machine, thoroughly tested in extensive practice, enables the farmer to make a seed-bed out of whole ground, and sow it at one operation; with an admirable tilth, perfectly straight rows completely finished up on the headlands as elsewhere, the seed planted at regular depth, and all without the trampling of a single hoof. It is also adapted for haulage by other systems of rope traction.

Mr. E. Hayes, of Stony Stratford, Bucks, has introduced various modifications into this system of a stationary engine and windlass, and rope laid out round the field. Between the two winding-drums upon the same axis are hung three riggers or band-wheels, any one of which may be driven at pleasure by a belt from a broad rigger or sheave on the engine fly-wheel. The middle rigger on the windlass is simply a "dead rigger;" each of the others actuates at a slower speed one of the drums, by means of spur-wheels inside. To reverse the action of the drums, then, it is only necessary to slip the belt from one outside rigger to the other, without taking any toothed wheel out of gear, and without stopping the engine—which is a source of trouble and delay when the engine has but a single cylinder. The revolution of the slack or paying-out drum is arrested, ready for the reverse motion, by the momentary pressure of a steam-piston brake. But no attendant is needed at this windlass; for Mr. Hayes leads out cords from the windlass around the field, by which either of the anchor-men instantaneously shifts the reversing bar, when the implement arrives at the end of its furrow. So that no signalling is required, except in case of obstruction to the plough while on its journey; and this enables the farmer to work in the thickest fog, or by moonlight in a pressing season, with perfect safety to the machinery.

The improvements of Messrs. J. and F. Howard, of Bedford, embrace all parts of the so-called "round-about" system. Their 10-horse double-cylinder ordinary portable engine, actuated the stationary windlass by means of a spindle with universal joints, in place of a driving-strap, which is liable to slip in wet weather. The two coiling-drums are hung upon eccentric bosses, or hollow axles, both upon one carriage axletree; and by altering the position of these eccentrics either drum is raised or lowered at pleasure, in order to place its toothed flange in or out of gear with one of the pinions on the first-motion shaft above. Thus a very light, though powerful, two-wheeled windlass is secured; the stopping and reversing are easy; the motion of the drums can be stopped without shutting off steam; the slack or loose drum, dropping upon a fixed block, becomes its own brake; and the amount of frictional pressure in this braking action can be regulated at will. The next point that meets our attention is the provision made for holding up the rope off the ground; not only to save wear, but to economize motive-power. A tight or pulling rope will always hold itself clear above the land, even upon low rope-porters; but a slack or outgoing rope, even if passed over porters 3 or 3½ ft. high, commonly trails by far the major part of its length along the ground. Now, it appears from the dynamometer experiments of Mr. J. F. Harrison, C.E., and Mr. J. C. Morton, in May and June last, that a very considerable proportion of motive-power may be sacrificed by imperfectly carrying the rope. The draught of 440 yds. of Mr. Smith's rope, wholly dragging upon the ground, and passing round three pulleys, was 3 cwts.—equal to about half the weight of the rope; and the draught of 700 yds. of Mr. Fowler's rope, wholly dragging on the ground, and passed round the clip-drum and one pulley, was 4½ cwts.—equal to more than one-third the weight of the rope. When imperfectly carried upon rope-porters, the draught was diminished nearly one-half; and when the rope was held clear from contact with the ground, the draught was only ¾ of a cwt.—only a sixth of the draught when trailing its full length. Hence we learn that, in dealing with fields of tolerable size, 3 or 4 cwts. of draught (representing, at a pace of 3½ miles per hour, 3 or 4 mechanical horse-power) may be wasted from not carrying the rope at all; while there may be a difference of 2 or more horse-power between partially and perfectly supporting the rope above the land. The necessary tightening of the slack rope might be effected by applying a brake to the paying-out drum, but it would be very undesirable to do this. It was found in the aforesaid experiments that, while the draught of a certain length of the Woolston rope (running over porters at intervals of 20 to 40 yards) was 2¼ cwts. when the slack drum ran loose, it was only 2 cwts. with the brake applied as usual; so that partial braking is an advantage. When the brake, however, was pressed so hard as to keep the slack rope entirely off the ground, the draught rose to 4 cwts. A simple brake, then, while saving a slight amount of power, as commonly used, would involve a great loss by friction, if employed to hold up the rope completely. Accordingly Messrs Howard adopt a method of returning to the pulling rope a portion of the strain which retards the slack or outgoing rope. At a few yards' distance from the windlass a compensating pulley, loosely hung between two fixed pulleys, pinches the hauling rope into the groove of one pulley, while at the same time pinching the slack rope into the groove of the other pulley—so that the outgoing slack rope helps to haul the pulling rope; and while the pressure in this self-acting apparatus is proportioned to the strain exerted by the windlass upon the hauling rope, there is no pressure at all when the rope is doing no work—thus enabling the portion of spare rope to pass freely to the windlass as the implement commences its journey. The rope is more effectually carried, owing to this contrivance, than it is by the brake alone; but what proportion of power is thus economized has not been well ascertained. The back and forward bending of the ropes between these additional pulleys must prove a source of considerable wear; and hence it is very desirable that whatever compensating movement is devised should be applied to the windlass drums, rather than to the ropes. Mr. Fowler has such a windlass with compensating brake; but, owing to the varying speeds of the drums (according as more or fewer layers of coils are wound upon them at different parts of the journey of the implement), only a portion of the retarding strain is returned to the hauling drum. Probably a simpler plan will be introduced, in which only a single layer of coils will be wrapped either drum.

Messrs. Howard's rope is laid out round five or six pulleys (according to the figure of the field and the position of the windlass), and these are of larger dimensions than the Woolston pulleys—which Mr. Smith considers large enough to be still portable (though the rope in passing them is bent round a curve of but 13 in. radius). With improvements in carrying the rope (without an excessive number or rope-porters), some change will probably be required in the present system of claw-anchors, which are already troublesome enough in some situations; permanent posts, or temporary posts and chains, being available in the absence of self-travelling anchorages. The Bedford rope-porters are remarkably handy for moving from and replacing under the rope; and those porters which are out of the track of the implement are admirable for catching a rope that rides or rebounds—as when crossing over a hollow. I need not describe the cultivator with tines that point both ways (for travelling to and fro without turning), and rock of their own accord,—so that when the fore point is depressed, the hinder one is slightly raised. It is remarkably light, and strong too, and shares of various widths—from 2 in. to 13 in.—enable it either to cleanly cut all the bottom, or break up without cutting when the ground is suitable. Two sizes of this implement are made, with three and five tines respectively. For reducing the broken soil a set of double-action harrows is employed, in a peculiarly light framing, steered in a similar manner to the cultivator by a lever-movement altering the lock or set of the forward wheels. Messrs. Howard's new plough consists of two sets of plough-bodies pointing towards each other, upon two lever frames, which cross at their inner ends within a short main-frame having one large furrow-wheel and a couple of land-steerage wheels; all three wheels standing very near together midway of the length of the implement. But the two sets of ploughs are raised or lowered into work independently of each other; the weight of each set being counteracted by separate spiral springs coiled in boxes, instead of either wholly or partially counterpoised by the weight of the other. And to netralize the tendency of the ploughs to rise out of very difficult work (particularly on hilly land), the action of the springs is so adjusted as to only lift a portion of the weight when the ploughs are in position for work, but sustain the entire weight when the set is raised into the air.

(To be continued in our next.)

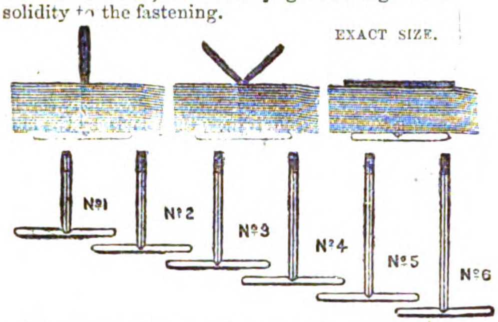
HART'S METALLIC CLIPS.

The following improvements in metallic clips for securing documents have been provisionally protected by Mr. H. W. Hart, engineer, of Fleet-street, London.

This invention refers to those T fastenings in which the leg or shank is composed of two separate pieces, which, after being inserted through the article to which the fastening is to be applied, are turned down, and embrace the article between the head of the T and the turned-down shank. Such fastenings, as hitherto made, are found to be weak, and readily open their whole length and break, or assume the form of a single strip of metal.

The present invention consists in stamping or otherwise forming the metal of which the fastenings are formed with legs or flanges, which, after the fastening has been bent into the T form, are turned down upon (by preference) the inner face of the head, and thereby give strength and solidity to the fastening.

EXACT SIZE.



The probability is that this invention will supersede the use of the ordinary eyelet, which requires tools for making the hole and fastening the eyelet in the papers, and which, when done, cannot be used a second time without destroying the articles fastened. This invention, on the contrary, can be used any number of times, from a few sheets of paper to an inch in thickness, temporarily or for a permanency if required.

GRANTHAM'S HYDRAULIC PRESSES.

FIG. 1

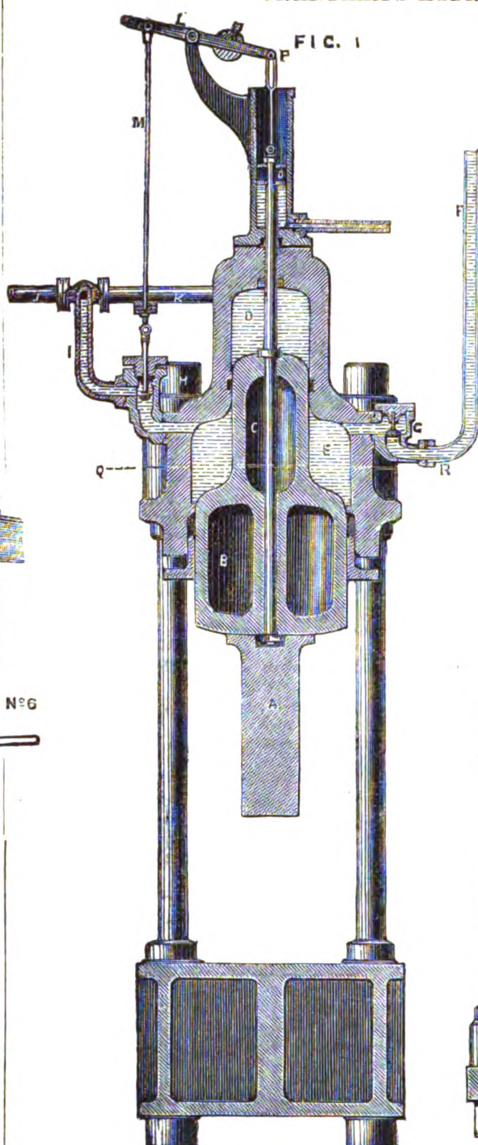


FIG. 4

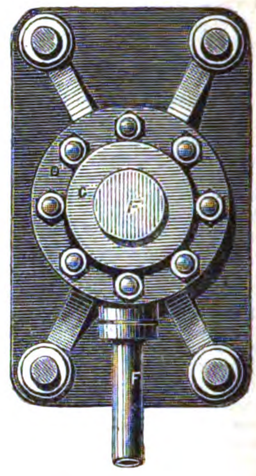

FIG. 3

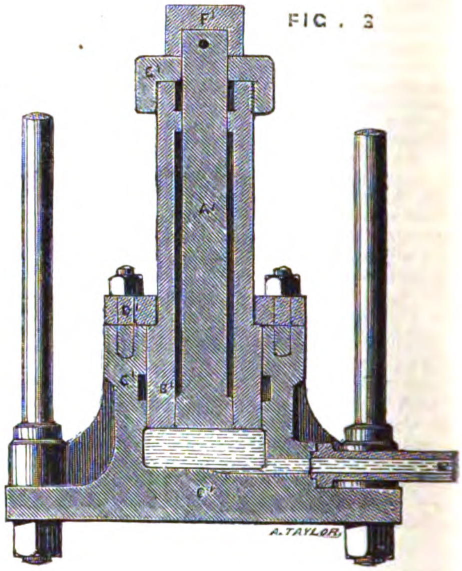

FIG. 2.

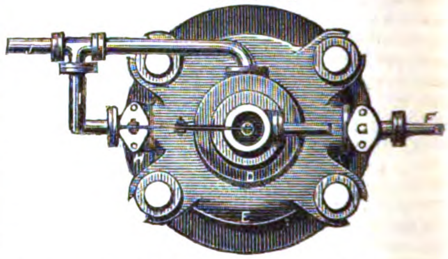

GRANTHAM'S IMPROVEMENTS IN HYDRAULIC PRESSES.

The object of this invention, patented by John Grantham, C.E., London, is to vary the amount of power given out by a single ram in a hydraulic press, although the pressure of water or other liquid may be uniform.

The first part relates to an arrangement by which the power exerted by the ram is increased at a certain distance or distances during the stroke, resulting in an economical process for packing or pressing any material into a smaller bulk, and which requires less pressure at the commencement than at the conclusion of the stroke, and especially useful where an accumulator is employed.

In order to effect this object, both the ram and cylinder in which it works are constructed of two or more diameters, each of which is provided with a packing of the ordinary kind. The ram has a telescopic shape, but does not slide within itself; its smallest diameter is first operated upon by the water pressure, by which it is forced to a certain distance, when the next diameter is also operated upon, giving an increased force, and so on to the next, according to the number of gradations in the ram, the power being increased proportionately to the increased diameter of the ram. The spaces between those portions of the ram and cylinder formed during the traverse but not yet supplied with the high pressure, are filled up by means of a flow of water at a low pressure from a pipe fitted with a self-acting valve, which closes immediately the high pressure is turned on, and prevents the water from receding. For the purpose of turning on the water from the accumulator or pumps to the increased diameter or diameters of the ram at the proper time and distance of traverse, a pipe is arranged, communicating either direct with the small end of the cylinder or with a supply pipe, and fitted with a stop valve and lever; this lever may be actuated in any convenient manner by the traverse of the ram, so as to set on the valve as required. Another convenient method for turning on the high pressure of water is effected by forming holes or longitudinal or diagonal slots for a certain distance on the side of the ram, so that when it has traversed such distance the water pressure may be communicated past the packing from the smaller diameter of cylinder to the next of larger size.

The second part of the invention relates to an arrangement in which the power exerted by the ram is greater at the commencement of the stroke than at the conclusion.

For this purpose the ram is made of a telescopic form, consisting of one ram sliding within another, of larger diameter but of less length, the external ram sliding within a cylinder provided with a shoulder or stop. When the pressure from the accumulator or force-pump is applied, it operates upon and actuates both the rams, which traverse together a certain desired distance, until they arrive at the projection or stop, when the pressure actuates only the internal ram, which, being of smaller diameter, exerts a diminished force and requires less water.

Figs. 1 and 2 refer to the first part of the invention, fig. 1 being a vertical section of the press.

A, B, C, is the ram (cast hollow for economy), and having two different diameters; D, E, is the cylinder with corresponding diameters. The part of the ram at C is worked in the cylinder at D, and the part at B is worked in the cylinder at E. A is the ordinary ram for the anvil; F is a pipe communicating to a well or cistern or low-pressure water supply; G is a self-acting valve which allows water to enter the cylinder from the pipe F, but which closes to prevent the water receding as soon as high pressure is applied; H is a stop valve communicated by the pipe I to the high-pressure supply pipe J, K; J communicating in the usual manner to the accumulator or force-pump, and K communicating with the small diameter of the cylinder D; L, M, is a lever and rod with adjustable balance weights, and attached to the valve H; N is a rod attached with the lift O to the ram, and by means of the slot at P actuating the lever and opening the valve at the required distance of traverse. Fig. 2 is a top view.

The process is as follows:—When the ram is

at the top of the cylinder the valve H is closed, the high pressure is set on to the cylinder at D, the ram is forced onward, the low-pressure water filling up the space formed in the cylinder at E. At a certain desired distance of the ram's traverse the rod N moves the lever and opens the valve H, when immediately high pressure is exerted in the cylinder at E as well as at D, closing the valve G, and exerting an increased force on the ram proportionate to the larger diameter of the part B.

Figs. 3 and 4 refer to the second part of the invention. Fig. 3 is a vertical section.

A′ is the small ram; B′, B′, is the larger ram with a shoulder—it is hollow, and fitted as a cylinder to allow the ram A′ to work within it; C′, C′, is the outer cylinder, fitted to allow the ram B′, B′, to work within it; D′, D′, is the stop attached to the cylinder C′,C; E′ is the water supply; F′ is the head to the ram A′; G′, G′, is the head to the ram B′, B′; fig. 5 is a top view of the apparatus. When the rams are at the base of the cylinder C′, C′, the force of the water actuates both rams until the shoulder of B′, B′, impinges upon the stop D′, D′, (which is the position shown in the drawing), when the ram A′ only is in action, and which slides within the cylinder B′, B′, the head F′ separating from the head G′, G′.

WANTED—PURE WATER.

Our sanitary authorities (says the *Building News*) have unanimously accepted pure water as a main feature in the requirements of man. Their effort to secure to the public the necessary element bears testimony to the difficulties that ever arise in a civilized and highly populated country in obtaining water in its state of purity. Pure water has been the cry that has lowered the water company's dividends to an alarming extent to the shareholders. Albeit, the public weal might receive considerable addition therefrom.

Still when we realize the fact, so well established as to be beyond all doubt, that the purer the water that enters our leaden conduits, the more poisonous it may be made before it reaches the consumer, we have to ask most seriously whether or not that great depreciation of stock is not lost, so far as the public advantage that might accrue from it, by the want of a proper knowledge of the medium through which the water is conveyed. A circular was issued, or a general notice promulgated, by the several water companies when the reservoirs were covered in and the various additions and improvements made in compliance with the new Act of Parliament relating thereto, requesting the consumers to clear out their cisterns that they might receive the full benefit of the purer supply. Still it left an equally important requirement untouched and almost unknown. In some districts, puplic attention has been aroused to the knowledge of the requirement of which we speak through the sudden death by poisoning of several members of a family, with the narrow escape of the remainder. The cause has been traced to the leaden pipes through which the water used by the family has been conveyed. We are not about to frighten our readers with a prognostication of sudden death to the consumers of water that has passed through leaden pipes, but ask their attention to a few facts relative to the characteristics of the medium through which they receive this universal element.

Firstly, we are informed by the highest chemical authorities, that pure water so rapidly acts upon lead, that in a very short space of time it becomes impregnated with this metal in a soluble form. Nor are we to escape by the comforting assurance that the water is impure. Water that contains carbonic acid (and what water does not, in a greater or less degree?) equally appropriates to itself a portion of the metallic medium through which it passes; these are facts from which we have no appeal. It is true that water may contain certain constituents that will act on the lead in a manner more favourable to a hygienic state of things, but do we take the trouble to ascertain if such a quality exists in our water? We think not. The result, is, therefore, that in the case of all new lead pipes, colic, next to poisoning, is the result upon all who use it; and in all cases, unless specially protected, poison, in the form of salts of lead, is administered, whether in homœopathic doses or after the more liberal allopathic system, and a deleterious effect is produced upon the system and health of all who partake of the liquid. The effect of sulphuric acid as a corrective, in the exceptional cases of which we have already spoken, is caused by the internal surface of the lead being changed from the metallic state into a sulphide of the metal which is insoluble in water. This reaction may be artificially produced by a simple yet highly scientific process, the discovery of Dr. Schwarz, of Breslau. This *savant* proposes the passing through lead pipes of a solution of sulphide of potassium, at a temperature of 212 deg., which changes the metallic lead into a sulphide of lead, and, thus transmuted, the water passing through it is perfectly free from the risk of contamination by any poisonous salt from the lead. It remains for the public themselves to decide, from our statements of facts, whether or not they will continue to tolerate even the skeleton of an evil that may be so easily exorcised.

MANCHESTER BOILER ASSOCIATION.

At the last ordinary monthly meeting of the Executive Committee of this Association, held at the Offices, 41, Corporation-street, Manchester, on Tuesday, September 29, 1863—William Fairbairn, Esq., C.E., F.R.S., in the chair—Mr. L. E. Fletcher, chief engineer, presented his monthly report, of which the following is an abstract:—

During the past month there have been examined 319 engines and 471 boilers. Of the latter, 4 have been examined specially, 4 internally, 49 thoroughly, and 414 externally, in addition to which 1 of these boilers has been tested by hydraulic pressure. The following defects have been found in the boilers examined:—Fracture, 5 (2 dangerous); corrosion, 16; safety valves out of order, 2; water gauges ditto, 20 (1 dangerous); pressure gauges ditto, 10; feed apparatus ditto, 2 (1 dangerous); blow-out apparatus ditto, 14; fusible plugs ditto, 8; furnaces out of shape, 1. Total, 78 (4 dangerous). Boilers without glass water gauges, 3; without blow-out apparatus, 21; without back pressure valves, 17.

Explosions.

Three boilers, not under the inspection of this Association, have exploded during the past month, from which four persons have been killed and three others injured. One of the boilers has been personally examined since the explosion, while this was prevented in the other cases by distance.

The first explosion, from which one person was killed and two others injured, happened to an agricultural boiler, while at work at a farm, driving a thrashing machine. It was not under the inspection of this Association.

The boiler, which was about twelve years old, was a portable one, of the multitubular locomotive type, and was worked at a pressure of about 40 lbs. per square inch. It was stated at the inquest that the safety valve worked freely, and that there was a due supply of water, the explosion being attributed entirely to a defective plate in the fire-box, which had been eaten away by corrosion, until reduced to one-sixteenth of an inch in thickness. This plate had been previously repaired, and at the time of the explosion was cracked through, and though it had for some days been leaking in consequence, had yet been worked on in that state.

The owner of the boiler was brought in guilty of manslaughter, the jury adding that they thought the appointment of a Government inspector to be highly necessary.

The second occurred to a new balloon or haystack boiler during the operation of testing at the maker's yard. It had not been constructed for raising steam for purposes of power, but was intended to be used as a chemical evaporating pan or still. It was not under the inspection of this Association.

The boiler—as another of similar construction and dimensions had recently been—was proved with steam, in order to test the tightness of the joints. The pressure, which appears to have been about 50 lbs., being raised, not by generating the steam within it by means of a fire underneath, but by communication with another boiler in work, to which it was temporarily connected for the purpose. Some five or six men were engaged upon it in caulking the seams at the time of the explosion, four of whom were blown to a distance from it; one of them, who was killed upon the spot, being thrown upon the roof of a house about 40 yards off, while two others died subsequently from the injuries received. The boiler was laid upon its side during the test, and gave way at the bottom, which was blown out entire, and thrown upon a roof about 10 ft. high and 13 yards distant, the shell rearing up on its dome end, and remaining in that position supported by a shear leg.

Its dimensions were as follows:—The height was 11 ft., the dome, from the appearance of which the term balloon boiler probably arose, was 9 ft. 3 in. in diameter, and the base 8 ft. 9 in., while the cylindrical sides were drawn in to 7 ft. 9 in. in the waist. The bottom, like that of a bottle, was concave, as is usual in these boilers, and rose 18 in. at the centre, in order to enable it to resist the downward pressure, being connected to the sides of the shell by a 3-in. angle iron, half an inch thick. The plates, which were from seven-sixteenths to half an inch in thickness throughout, were some of them second-hand, those forming the dome being new, the remainder having been used in a boiler before. They had, however, been worked to their new shape, their edges sheared, and the holes punched afresh. The rivets, which were three-quarters of an inch in diameter, were centred from $1\frac{1}{4}$ in. to 2 in. apart, and the general workmanship appeared satisfactory.

The rent between the bottom and sides of the boiler had occurred, for the most part, at the lower ring seam of rivets in the cylindrical portion of the shell, but not altogether so, some portion of the rent running through the rivet holes at the outer edge of the circular bottom plate; while, from the upward position in which the latter was thrown by the explosion, it appeared most probable that the rent had commenced at that part of the boiler which lay nearest the ground at the time of the explosion, and thus, from the position of the fractures, must have started at the cylindrical part, and not at the bottom plate. The reason of this is not very apparent—since there were two other ring seams of rivets in the cylindrical portion of the boiler which were quite uninjured, although subjected to the same direct pull, which, after allowing for the rivet holes, did not amount to two tons per square inch of metal, added to which, the longitudinal strain thrown upon these circular seams in cylindrical boilers, is only half of that which occurs in the transverse direction, so that it is difficult to account for the rent selecting the lower ring seam of rivets, or indeed for its occurring at all.

Whether, however, the rent in question was due to some undetected flaw in the iron, or whether the plates had been crippled in being brought together, which is too frequently the case, or whether an unfair strain was caused by the springing of the eighteen bottom plate, which, although arched eighteen inches in the centre, was yet flat as compared with the hemispherical top; or whatever may have been the cause that started the rent, one thing is certain—that the application of the hydraulic test would have detected and exposed the weakness, prevented the explosion, and saved the three lives. It is, therefore, again earnestly recommended that in all similar cases this precaution should be adopted; and it is trusted that it will not be necessary for any further additions to be made to the list of fatal explosions—already sadly too long—before the adoption of the simple and inexpensive hydraulic test becomes universal.

Cavalier Novi, formerly Lieut.-Colonel of the Ordnance, on the 5th of February last, read at the Royal Institution of Naples a Paper entitled "Substances for the Preservation of Iron, Cast Iron, and Steel." It was approved and inserted in the reports of the Academy. After having enumerated the principal means for preserving iron adopted by the ancients, and still more recently down to modern times, he confines his attention to the three following compositions for coating iron works:—1. Varnish composed of resinous matter, such as essence of turpentine, galipot, resin, colophony, &c. 2, varnish in the composition of which there is; quick essence of coal tar and dry pitch of the same tar; 3, varnish the composition of which is derived from asphalte and its quick essences, mixed with oxides and various colouring substances. He concludes by saying that the future preservation of iron depends on the positive use of asphalte and its results. In the month of August the French Government directed that experiments should be made on these compositions.

LAW AND DOWNIE'S TRACTION ENGINES.

Fig. 1.

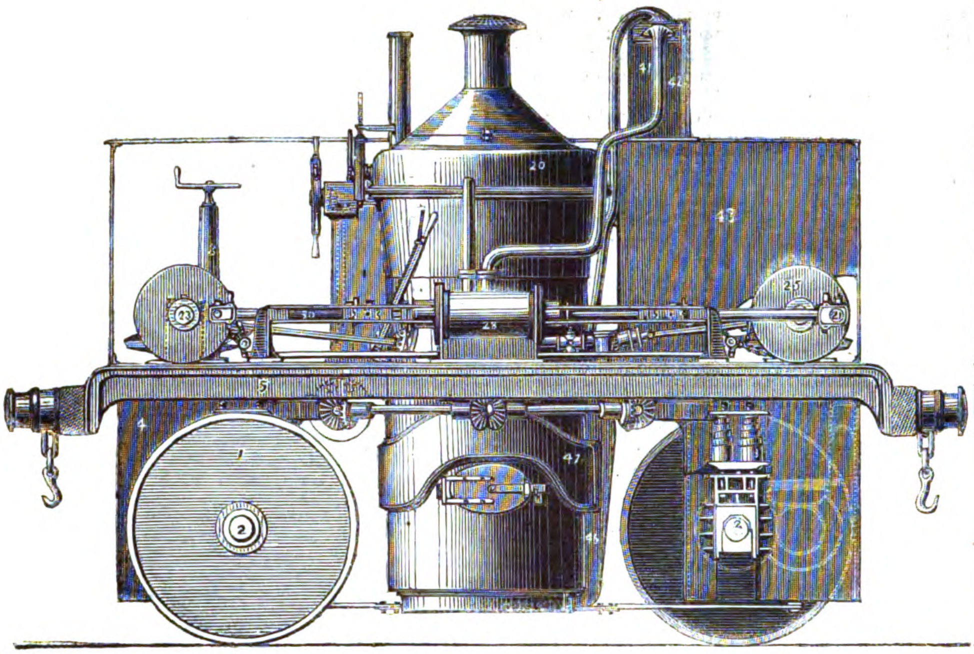

Fig. 2.

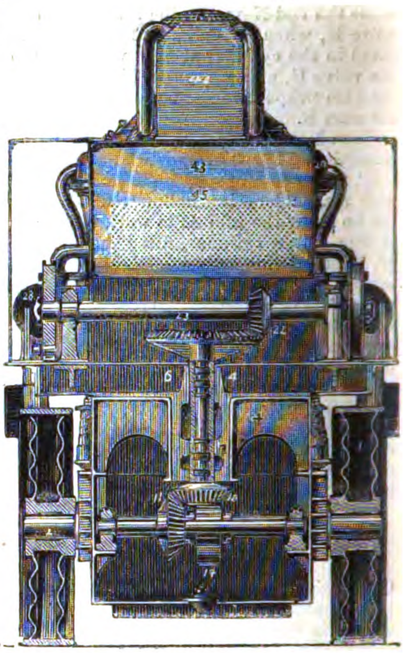


LAW AND DOWNIE'S TRACTION ENGINES.

The following improvements in traction engines have been patented by Messrs. Law and Downie, engineers, Glasgow.

This invention has for object increased efficiency in traction engines, with economy in cost and facility and convenience in manœuvring.

Fig. 1 is a front elevation of one modification of the improved traction engine, with the outer shell or casing removed, to show the details in the interior, one of the wheels being also supposed to be removed to show parts that would have been hid by it; and fig. 2 is a transverse vertical section.

In this improved traction engine there are two pairs of carrying or main driving wheels, and an important feature is the making of all four wheels both driving wheels and steering wheels. The steering is effected by inclining the axles horizontally in opposite directions, the axles being driven by gearing arranged so as not to be interfered with by this inclining of the axles. Each pair of wheels has mounted on it, on springs, a kind of bogie; and the two bogies support the main carriage framing, and are connected thereto so as to be capable of swivelling for the steering action already referred to. The main carriage framing is, in this example, a kind of platform built up with longitudinal and transverse wrought-iron ribs or beams placed vertically, and strengthened by angle irons, being covered by floor plates. At each end there is built into the wrought-iron framing a cast-iron ribbed frame-piece, which bears in each case upon the corresponding bogie, or this framing may be entirely of wrought iron. Each end frame piece is formed with a tubular trunnion 7 projecting downwards, and on which the bogie swivels, being made with a socket to fit and turn upon it. In the vertical axes, about which the bogies 4 swivel, that is, in each case in the tubular trunnion, there is a vertical shaft 8 fitted with a bevel wheel 9 on its upper end, and with a bevel pinion 10 on its lower end. The bevel pinion gears with a bevel wheel 11 on an intermediate horizontal shaft, mounted in bearings in the bogie, with which arrangement the swivelling of the bogies for steering purposes merely causes the bevel wheels to, as it were, roll round the bevel pinions 10 on the vertical shafts without affecting the transmission of the power through the wheels. The intermediate horizontal shaft 12 of each bogie is fitted with a spur pinion, which gears with a spur wheel 14 fast on the main driving wheels' axle, and this spur pinion 13 is, by preference, directly under the swivelling centre of the bogie, or as near thereto as can be conveniently managed, and is made with the teeth slightly curved across their acting faces, so that the teeth are slightly thicker at their middles, with which arrangemnt the carrying wheels 1 and axle 2 can accommodate themselves to inequalities of the road without disturbing the engine or gearing. The axles 2 are arranged with axle boxes and springs 3 in a manner similar to that sometimes adopted in railway rolling stock. The bogies 4 are made to swivel, as required for steering purposes, by means of toothed segments, fixed upon them, and acted upon by worm wheels, and one of the worm-wheel shafts is connected by bevel gearing with a hand wheel, mounted upon a standard, whilst the two worm-wheel shafts are connected by intermediate shafts and bevel wheels, so as to be actuated simultaneously. This gearing is arranged to turn the bogies in opposite directions, whereby a doubled steering efficacy is obtained with a given adjustment, whilst, from the swivelling wheels being at the same time driving wheels, the steering action is thereby rendered the more certain and powerful.

Various arrangements of steam boiler and engine details may be provided for driving the apparatus which has been described. In one modification, a multitubular boiler, of the vertical class, is employed, and this boiler may be suspended by trunnions, as shown in fig. 4, so as by its own weight to remain vertical, although the carriage may be ascending or descending an incline. The boiler 20 is placed centrally and between the bogies and their vertical driving shafts 8, being fixed to the main framing 5 by flange plates or brackets (which are not shown). The vertical shafts are actuated by bevel pinions upon transverse horizontal shafts, mounted in bearings upon the platform or main framing. The transverse horizontal shafts are at each end fitted with overhung discs 25, provided with crank pins, whereby they are driven by means of two steam cylinders 28, arranged on the main framing, one on each side of the boiler. The pistons are fitted with long piston rods, working out at both ends of each cylinder, and having both ends fitted with slide blocks working in guides and jointed to connecting rods, which are jointed on the several crank pins. Any other convenient arrangement of the steam-engine details may be adopted in place of that described. Frictional brake straps 31 are applied to the four crank-pin discs 25, being arranged to be actuated simultaneously, and giving the power of bringing the machine to a dead stop in a very short space. The brakes are actuated by means of a vertical screw spindle, fitted with a handle, and mounted in a pillar. The screw spindle acts on a lever fast on a transverse horizontal shaft, which acts directly on the brake straps at the end, and simultaneously, by means of rods, on the brake straps at the other end. The steam cylinder valves are worked by means of the ordinary reversing link-motion 36, and the eccentrics are conveniently placed on one of the crank shafts, whilst on the other crank shaft are placed eccentrics for working the feed-pumps.

The several arrangements which have been described permit of the centre of gravity being kept low, and with the centres of the wheels closer together than usual with other plans, whilst extreme portability and compactness is ensured. The two ends of the engine are reversed duplicates of each other, whence arises economy and simplicity in construction, whilst the engine may move in either direction with equal facility, whereby the frequent necessity of turning will be obviated.

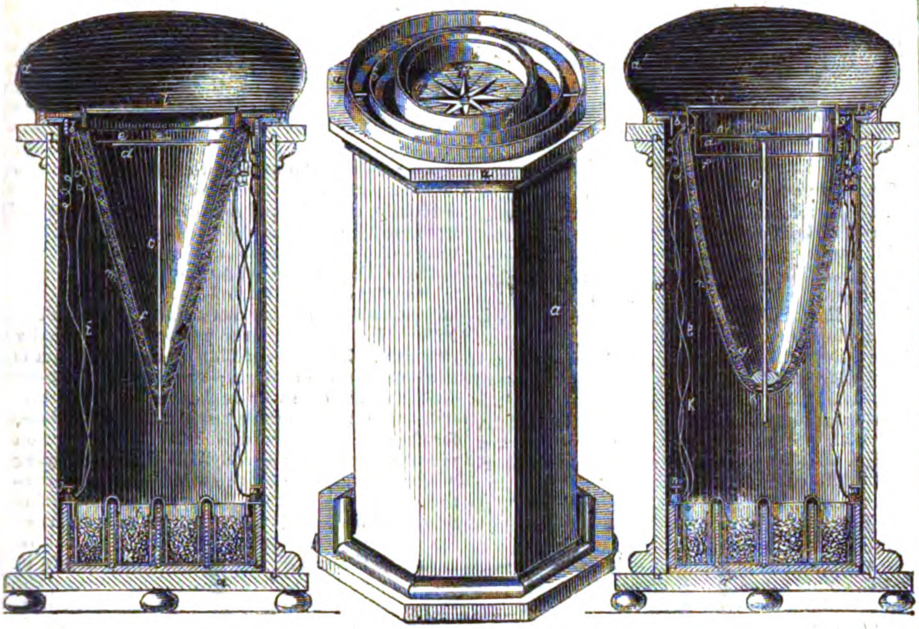
The details described are obviously susceptible of various modifications, and the invention also comprises improvements in other details; thus the engine may be fitted with more than two pairs of wheels, and every pair or only two pairs may be made driving wheels. The engine may also be made to carry a load, or it may be arranged to transmit driving power to the wheels of one or more lorries or waggons coupled to it. The engine may also be fitted with a crane or with other hoisting or winding details to be driven by hand or by engine power.

It is intended in general to provide the usual blast pipe and steam jet in the chimney to assist the furnace draught; and in addition to these appliances, provision is made for exhausting the waste steam from the cylinders into the feed-water tank through a box fitted with divisions of wire cloth, or the like, to suppress the sound and the external appearance of white vapour, and at the same time to heat the feed water.

The modification of engine shown in figs. 1, 2, and 3 is represented as provided with these im-

GISBORNE AN SIMPSON'S SHIPS' COMPASSES.

Fig. 1. Fig. 2. Fig. 3.



proved arrangements. The exhaust pipes 41, from the steam cylinders, are made to communicate with the top of a box 42, placed on the top of the water tank, with which tank the bottom of the box 42 is in open communication. In this box there are placed a number of horizontal diaphragms of wire gauze, through which the exhaust steam has to pass, noise being thereby prevented, and the steam more or less condensed, whilst it imparts heat to the feed water. To render this action the more efficient, branch pipes, with which the feed-pumps may be put in connection when not feeding the boiler, are carried from the feed-pumps, and unite in a single pipe, which discharges the water into the top of the box 42, and the water falling like a shower through the wire gauze diaphragms, and carrying along with it the steam, promotes its partial condensation, thereby rendering the necessity for supplying the feed tank less frequent than in ordinary arrangements. Further, as the heat imparted to the feed water is considerable, a number of tubes are fitted longitudinally across the tank, and air entering these tubes at their outer ends tends in passing through them to keep down the temperature of the water for circulating purposes. From the tubes the air passes into a duct 46, which communicates with the ashpit and with a belt, which encircles the boiler above the grate bars, the air being admitted into the furnace from this belt by tubes which cross the water space surrounding the furnace. A donkey-engine feed-pump is provided as usual for feeding the boiler when the main engines are not working, and can also be used when the engines are working to keep up circulation in the feed tank, by withdrawing water from the lower part and discharging it into the condensing box 42. This pump is also provided with connections to enable it to be used for drawing water from a road-side stream or trough to supply the water tank, and thereby rendering special watering stations unnecessary. Where rapid manœuvring is required, the donkey-engine may be arranged to supply power for working the steering details, the steersman in that case having merely to set levers or hand wheels for putting the necessary motions into or out of gear, or the steering gear may be worked by a special cylinder or pair of cylinders, the action of which may be regulated in various ways; thus, by one plan the steersman by turning the steering wheel actuates the valves of the cylinder or cylinders, which last actuate the steering details in a precisely correponding direction and degree.

GISBORNE AND SIMPSON'S IMPROVEMENTS IN SHIPS' COMPASSES.

This invention, patented by T. S. Gisborne, E. E., Birkenhead, and Mr. W. Simpson, of Liverpool, consists of the use or employment of electricity, to render insensible to local attraction, or to overcome or countercheck the local influences which have so often and so seriously affected the magnetic needles in ships' and other compasses. And although this invention is more particularly serviceable in compasses to be used on board ship, it is not exclusively so applicable, as it may be applied or used to or with other compasses.

The best mode or arrangement for "the employment of electricity" for the purpose above named, consists in passing a current of electricity from an ordinary battery through a coil of insulated copper wire wound around a hollow conical or semispheroidal compass box, or wound around a hollow conical or semispheroidal-shaped dish encircling the compass box. In either of these arrangements the magnetic or compass needle rests on a centre pin; or when there are more than one, they are secured to the card or other part, which rests on the pin in any usual way, at a short distance below a straight line drawn horizontally across the upper termination of the coil and below the mouth or termination of the conical or semispheroidal-shaped box or dish, the leading features of construction of compasses at present in use being retained.

In figs. 1, 2, and 3 of the accompanying drawings, the same letters of reference denote the same parts. *a* represents the binnacle; *b*, the compass bow; *c*, the pin for carrying the needle *d* and card *e*; *f*, the compass box, made of sheet copper or other material into the shape shown and supported on gimbals *g*, as in ordinary compasses. On the outer surface of the said conical compass box *f*, there are fastened, by soldering or otherwise, a number of projecting pins or pieces *h*, which keep the insulated wires *i* in their places around the compass box *f*. The insulated wires *i* are here shown to be two in number, but one only, or any larger number, may be employed; at *j* they are connected, after sufficient slack has been left for free movement of the compass to, and communicate with, the battery *k*, shown as of the ordinary sand or sulphate of copper description, although any other kind of battery or means of maintaining a continuous current of electricity would answer the same purpose. The currents of electricity may be made to travel in any direction; but in practice it is advisable, indeed almost indispensable, that the currents should pass around the cone, and consequently around and below the magnetic or compass needle or needles in opposite directions—that is, the layer of insulated wire next the cone may have the electricity passing in one direction, whilst the layer over it may have the electricity passing in the opposite direction, or two insulated wires with the positive end of one and negative end of the other laid together may be taken and wound around the cone. *l* is the glass cover; *m*, shows a protecting covering of gutta percha or other material, preferably impervious to moisture.

To arrange or set either of the apparatus above described for use, it is only necessary to connect the wires to the battery, when, if the insulation is good, a continuous current of electricity will pass from one pole of the battery to the other through the coil, and in so doing the effect is to counteract practically all local attraction of the magnetic needle or magnetic needles in ships' and other compasses, and give a "true north pole."

SOUTH WALES INSTITUTE OF ENGINEERS.

The annual general meeting of the members of this Institute was held at the theatre of the Royal Institution, Swansea, on Saturday last—the President, T. Evans, Esq., F.G.S., and Government Inspector of Coal Mines for the South Wales District, in the chair. Lionel Brough, Esq., the Inspector for the Bristol and West of England District, and about fifty other members of the Association, were also present.—The President, in opening the proceedings, observed that six years had passed away since the promoters of the South Wales Institute of Engineers met together at Methyr and held their first meeting in that great centre of mining and manufacturing industry. They were but few in number, inexperienced in the conduct of such matters, and labouring under innumerable difficulties. Those difficulties, however, had been surmounted, and their numbers had increased far beyond their expectations, and he could now designate the Institution as a most important and flourishing body. During the past year, however, death had been amongst them, and they had now to deplore the loss of three most valuable members—viz., Mr. Ebenezer Rogers, of Abercarne (one of the early promoters of the Institution), Mr. Benjamin Dodd, of Blaenavon, and Mr. Samuel Baldwin Rogers, of Chepstow, the inventor of the iron bottom in the puddling furnace, which had proved of such incalculable benefit to the iron trade.—The Secretary having read the report for the last year, the members proceeded to the discussion of Mr. William Firth's Paper on "Coal-cutting by Machinery," this subject is at present creating considerable interest amongst scientific men, and several of the learned associations of the day are discussing the feasibility of adapting machinery to cutting coal. The writer of the paper in question is an advocate for the introduction of the coal-cutting machine, and minutely describes that in use at West Ardesley colliery, near Leeds. The motive power is compressed air, and the machinery so simple, that it is but little liable to derangement. One penny per ton will amply cover wear and tear of machinery, interest, and redemption of capital, on a daily get of 500 tons. The get of large coal by machinery over manual labour was also most satisfactory, and a total saving of 7d. per ton was realized. Upwards of 40 per cent. of the loss of life in coal mines arises from falls of coals or roof. The introduction of machinery will reduce the number of persons exposed to these casualties at least one half, and consequently a considerable saving of life must result.—During the discussion which ensued, Mr. Brough, Mr. Bedlington, Mr. Birkbeck, and others, believed that the proper power for propelling machinery under ground had at length been discovered, and that coal-cutting machines could be advantageously used in the North of England, where there were good roofs and good bottoms, and where the wages for cutting were very high. They, however, questioned the use of such machines in the South Wales mines, where the roofs and bottoms were bad, and where wages were low. They believed also that the loss of power would be very great in collieries of large extent; and what was still more objectionable to the introduction of these machines in Wales, was that the pick was driven with such force that, if it came in contact with pyrites, it struck fire, which was very dangerous in fiery veins like those of Wales. The members generally seemed to admit that the first great difficulty, the propelling power, had been

successfully overcome, as, mechanically speaking, the engine answered every purpose, and they hoped the day was not far distant when the other obstacles would be removed, and coal-cutting by machinery universally adopted, resulting in a great saving of human life.—The following Papers were then read, and ordered to be printed for discussion at the next meeting :—"On surface condensation, and the use of distilled water in boilers," by Mr. Turner, of Lansamlet, near Swansea; "Description of a mode adopted in sinking a pit through quicksand," by Mr. John Glassbrook, of Morriston, near Swansea; "On long work in collieries," by Mr. John Williams, of the Letty Shenkin Colliery, Aberdare; and "On coal and ironstone mining in Scotland," by Mr. Ralph Moore.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post-office orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

RECEIVED.—F. W., G. W., G. P. W., R. D., W. G. and Co., W. W., Capt. N., R. T., J. N., G. L. W., W. P.

H. H. A. (Birmingham).—All the registered designs appear in our pages. But few have appeared recently. The next list will appear in a week or two.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Living in a colony, I am, like most others of my calling, often put into unpleasant straits by want of carriage for my produce to the seaboard and supplies to the estate.

Do you think a road engine would be of any assistance? The distance to the port of shipment is 96 miles—the road, as a rule, fairly good, but over a pass of 1,500 ft. above the general level of the country, and a small portion, on each side, at a very steep gradient (say 1 in 8 or 7), but only for 200 or 300 yards. There are also two or three sharp corners to turn. Mail coaches with passengers run the whole distance at an average speed of eight miles an hour. I should, when I could get them, have to carry my own coals; at other times, wood must be the fuel. Coals average about £3 per ton at the port. Carriage by bullock-carts ranges from £3 3s. to £5 15s. per 16 cwts. Occasionally it goes to double and treble this last rate, but that is very unusual. An Englishman would, of course, be required as driver. Now the questions I should like to put to you are:—

Would any description of road engine be economical; and would it be possible to get one that would not, with fair treatment, get out of order? If so, what makers would be to be preferred, and what guarantee should I have that it would not fail on the first or second journey, and thereby entail a heavy loss?

What would be the price of such a machine, on board, with duplicate parts most likely to fail?

Would a copper boiler be worth the extra cost?

Allowing 20 per cent. for wear and tear, at what rate per ton per mile should I get it to draw loads? By wear and tear, I mean fair wear and tear, exclusive of breakages and accidents, for which a liberal allowance ought to be made.

In case of your handing this over to any manufacturer who might like to speculate to the extent of the postage of a priced list and description, I add my name and address, but remain to you as

Your obedient servant,
PLANTER.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

"THE GREAT EASTERN."

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Long ago I recommended in your columns two screws to be placed one on each side of the rudder-post to facilitate the steering of this vessel. This the daily papers have lately described as having been tried successfully in another steamer. It now appears also the mountainous paddles become injured in a stormy sea. Permit me to suggest that they be removed altogether, placing instead three paddles with their appendages on each side. This could be done with present steam engines, with the addition of shafts, cranks, and lower bearings than the present ones. The steerage power of the "Great Eastern" would, with this alteration, be equal to any conceivable emergency, as the paddle abaft midship on one side could be reversed, whilst the forward paddle on contrary side is working onwards. Besides, with any sea one of the sets of paddles would be working efficiently.

Yours truly,
GEORGE WALCOTT, C.E.

STEAM BOILER EXPLOSIONS.

SIR,—In your last impression I observe that Mr. Clark refers the origin of the "projectile theory" of boiler explosions to a private conversation between himself, my friend Mr. Holley, and myself, on some day not named, but "shortly after" the explosion on board the "Great Eastern." Mr. Holley was on board the ship at the time of the disaster—viz., 5.50 p.m. Friday, September 9th, 1859, and narrowly escaped with his life. Before quitting the vessel he made himself thoroughly acquainted with the structure and fittings of the feed-water casing, and with the conditions under which it had worked. He returned to town the next (Saturday) evening, and came immediately to my rooms. With the light which he gave me, I at once formed an opinion of the cause of the explosion. I saw that the casing must have been nearly full of water just before it exploded, and that the funnel, having no stays, must have collapsed under a moderate pressure. In collapsing, some of the joints would be likely to open, and thus the steam, pressing upon nearly eleven tons of water heated, perhaps, to 300 deg., would be instantly liberated. As to what would be the result, I immediately formed the opinion I have ever since held—an opinion which, as I believed, was clearly expressed in a leader in the *Engineer* of the following Friday. My views were formed on the evening of September 10th, 1859; and Mr. Holley, who adopted them in his letter to the next number of the *Engineer*, understood and shared them with me at the time. We met Mr. Clark a few days afterwards and I mentioned my view of the case to him. He offered some explanation of his own—one which I was unable to understand at the time. On a subsequent occasion he appeared to agree with me; but he has since advanced an explanation (one which, possibly, may have been that which he suggested in the presence of Mr. Holley and myself), and which, now that I do understand it, I dissent from altogether. I may add that Mr. Holley is now in England, and that Mr. Clark can easily refer to him should he wish to do so.—I am, &c.,

ZERAH COLBURN.

SIR,—It appears to me to be rather an idle discussion, whether Mr. D. K. Clark or any other man originated that particular theory of the violence of boiler explosions which that gentleman advocates. The theory in question insists on the projection of the water and its percussive action as being the prominent agency in the production of violent effects. Now every man who has drawn the cork of a bottle of ginger beer recognises and understands this action. The fact itself is plain enough, and the only novelty in the application and *rationale* of the thing is the distinction which Mr. Clark makes between the momentum of the steam and the momentum of the water projected, contending that the latter, as "a heavy projectile" . . . "shatters the boiler in a manner not to be accounted for by simple over-pressure or by simple momentum of steam." Now this distinction would be relevant to the subject, and the conclusion drawn therefrom of "the sudden projection of the water in the boiler being the great cause of the violence of the effects," would be perfectly correct, if the water were projected with the same velocity as the steam. This, however, is not the fact, but it is covertly assumed as such; and as a condition for consistency of thought, it must have underlaid all Mr. Clark's ideas on the subject.

On the 3rd and 10th of May 1861, Mr. Clark addressed you on this subject; and on the 17th of the same month you published a communication of mine in which the fallacy here adverted to was fully exposed. No reply was made to it; and I thought, therefore, that my reasoning was satisfactory, and the refutation unanswerably complete. But error possesses great vitality, and comes to the surface again and again. Will it be out of place then to re-state, in brief terms, the argument which on the former occasion I employed—namely, that if a given repulsive force imparts motion to bodies which differ in their mass, the respective velocities will be inversely proportional to the masses, that is to say, in the inverse ratio of their specific gravities; consequently, a particle of steam and a particle of water will impinge on the broken and separate pieces of the boiler with no grater momentum, the one than the other? I speak of the fragments of the boiler, for, of course, no projectile and percussive action can take place until the boiler by simple over-pressure is actually ruptured. But this equality in the momenta is truth only in the abstract; and the practical conditions of the case will make the actual result still more unfavourable to Mr. Clark's notions, for the said particles will have to impinge on pieces of the boiler already in motion, and flying with a velocity due to the pressure that causes the explosion, which velocity, if the magazine of steam be large, may well be greater than that which the necessarily lesser pressure, now acting on the water, will be able to impart to it. So that possibly, according to circumstances, the water may have no projectile action at all on the fragments of the boiler. At any rate, it could only act with its relative velocity. Now that relative velocity is immensely in favour of the steam, by reason of the immense difference in the absolute velocities imparted to the steam and to the water. Again, in the case of the water, we have to take into account the time lost in consequence of the secondary character of the action upon it of the repulsive force, during which the fragments of the boiler have already been projected by the primary action of the force, and have gotten the start of the water.

But, in opposition to Mr. Clark's notions, I imagine the real fact is, what the Astronomer Royal, in his recent communication to the British Association, assumes it to be—that the second action of the force is the conversion of part of the water into steam, which, of course, will further delay the projection of the remainder, through the instrumentality of the steam so produced; thus constituting the third action of the force in the order of time. For as to any inherent projectile force proper to, and operating on the remaining water, it will be altogether robbed of that by being robbed of its heat. Thus, in Mr. Airy's opinion, the entire destructive energy of the explosion resides in the steam, in its conjoint action simultaneous with and subsequent to the rupture of the boiler—a conclusion to which the common sense of observers has all along directed them. There is nothing new in the observation; but Mr. Airy has endeavoured to give some precision to the estimate of the remanent force in the steam liberated from the water by the explosion. It is, however, more specious than real, and this is a qualification which necessarily attaches to all mathematical estimates of practical matters in the abstract; and yet there is a charm, as well as an illusion, in obtaining precision and certainty, although it be only in the abstract.

The practical points which are not amenable to calculation, but which have an influence upon the effects—and it is here where precision and certainty have any importance at all—pertain in part to the secondary nature of the action of the force in its evolution from the water, for it is in time that it follows the first, and it takes other time in the extrication of the steam. These are circumstances connected with the physics of the subject, and the mathematician cannot fix and determine such; they are dependent too, in degree, on other circumstances of a practical kind. Now, time is the all-important element in the efficiency of steam as a destructive agent, and yet we are unable to bring it to account. We may arrive, even in an explosion, at a tolerably satisfactory estimate of the efficiency of steam, as a

cause, in the aspect of mechanical power, labouring force, or energy, as it is now the fashion to call it; but that is of no avail unless we can supplement the time. The work done will be the same, although it should take a moment or a month in the doing, but the destructiveness of percussion does not follow that rule. A cubic foot of water at 60 lb. pressure of steam, is found by Mr. Airy to be equivalent to 1 lb. of gunpowder, but both the one and the other may be very harmless under a slow development of their powers. In this comparative estimate, by-the-bye, the "*accurate* integration" concerning the one is mixed up with a mere guess at the destructive energy of the other, the loss thereof in Didion's experiments being *supposed* to be *one-half*. Verily, mathematical accuracy and precision are fain at times to put up with a very incongruous kind of companionship. The truth is, that the power of the science for all practical affairs is bounded within exceedingly narrow limits, and the sole recommendation, generally speaking, of mathematical conclusions concerning them, is mathematical *prestige*.

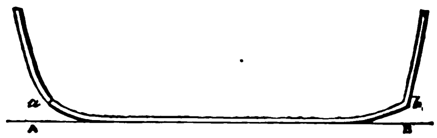
Yours, &c.,
Sept. 28. Benj. Cheverton.

SHIPS' WATER-MARKS.

Sir,—As the Mechanics' Magazine is extensively read by naval architects, and others connected with our mercantile marine, it may prevent an accident of a very serious character if you publish the following caution respecting the "*water-marks*" placed on ships' stems and stern-posts.

I have seen several vessels with their keels "cut up" (as it is technically called) at their stems and stern-posts, and their water-marks, in consequence, have given an erroneous indication of their draft of water.

Let A B be a straight horizontal line continued



forward and aft along the base of the keel. The keel being "cut up," that is, curved upward as at *a* and *b*, the water-marks are placed so as to show the draft of water above *a* forward, and *b* aft; instead of showing it above the line A B.

The consequence is that, when a ship so marked is about to be placed upon blocks in dry dock, the captain may be oblivious or ignorant of the keel being so cut up at its two ends, or at either of them, and the ship may actually draw a foot more water than she appears to draw.

Within the last few days, a ship of this kind was being hauled into dry dock. The water indicated upon the beacon at the head of the blocks, was considerably more than the ship apparently required, and abaft there was a still greater superabundance. But, before the ship could be placed in her intended berth, she stopped, as the men were hauling her to it; and some of the blocks making their appearance on the surface of the water it was manifest that she had pressed upon those blocks and tripped them. Considerable force was required to get the ship clear of the blocks, and if this had not been effected, she would have grounded upon them in such a manner, in all probability, as to have strained and broken herself very seriously.

Nauticus.

Miscellanea.

A monument to the memory of the late Samuel Colt, the inventor of the revolver, is to be erected at Hartford, Conn., of Scotch granite. Mr. J. G. Butterson, of that city, the designer of the Worth monument, New York, has gone to Scotland to select and purchase the granite. The monument is to cost 25,000 dols.

A French engineer has made an improvement in making macadamized roads that promises good results. The main feature of the invention is a steam roller, to consolidate gravel and broken stone. A pair of cylinders, inclined at 49 degs., act on an outside crank on one end of the axle of the main roller or drum. The front axle has broad wheels, and is controlled by steering gear similar to that used on steam carriages and traction engines. This machine can run both backward and forward with equal facility, is easily reversed, and can work on a short piece of road until sufficiently consolidated.

We learn that the Plymouth Iron Works, at Merthyr Tydvil, to the creation and improvement of which the late proprietor, Mr. Anthony Hill, devoted a valuable lifetime, have recently been purchased from his trustees for a quarter of a million sterling by three gentlemen whose acknowledged experience, ability, and command of capital will, doubtless, maintain and increase the well-earned reputation of the works. The purchasers are Mr. Richard Fothergill, of the Aberdare Iron Works; Mr. Thomas A. Hankey, banker; and Mr. Benjamin Bateman, iron merchant. The property of which they have become possessed comprises 3,000 to 4,000 acres, abounding in steam coal, ironstone, limestone, &c., sufficient for a produce of iron nearly double the present make. About 6,000 tons of coal are raised weekly, and this quantity may be very considerably increased. The works are remarkably well situated as regards water power, and the machinery and appliances are of the most extensive character. There are eleven blast furnaces, producing about 1,000 tons of cold-blast pig iron weekly, as well as forges, rolling mills, &c., equal to the production of about 800 tons of finished iron weekly.

Workmen are now busily engaged in making the excavations in Seymour-street, for the extension of the pneumatic despatch from the Euston Station of the London and North-Western Railway to the General Post-office in St. Martin's-le-Grand, and to Messrs. Pickford's depôt in Gresham-street. The total additional distance between Euston-square and the City will be 2½ miles, making with the distance between the North-Western District Post-office and Euston-square, now in daily operation, a length of 3½ miles. A 54-inch tube, instead of 30-inch, is now being constructed, and it is expected that the line may be so far completed for the transmission of the Christmas traffic into the City from the London and North-Western Railway at that period.

The iron trade in the North continues to improve. There are at present 125 furnaces in blast, producing about 21,500 tons weekly. The total deliveries continue steadily in excess of the make, and will be this week fully 25,000 tons. Consequently the stocks are about 35,000 tons less than they were four months ago. The malleable ironworks, foundries, and shipbuilding yards on the Clyde were never so actively employed and so full of orders. So great is the demand for iron for shipment and local consumption, that ironmasters have raised their prices 2s. to 3s. per ton.

At Woolwich, an experimental 300-pounder Armstrong gun, after being fired nine times, was found defective near the muzzle, in the same way as many of the 12-pounders.

The French Minister of Commerce, having recently sent to the Rouen Chamber of Commerce specimens of the Siamese nettle or China hemp in various states of preparation, experiments have been made to ascertain its value as a textile substance. The result, as announced by the Chamber, is that, when mixed with cotton in the proportion of one half, excellent yarn may be produced at a cost of 30 per cent. cheaper than from Louisiana cotton at its present price. The Chamber calls the attention of manufacturers to this important fact, and requests them to inspect the specimens placed at their disposal.

There has been a great decrease in the exports of coal from the various ports of the Kingdom during the past month. As compared with the corresponding month of 1862, the decrease is as follows:—From the northern ports, 13,082 tons; Yorkshire ports, 8,463; Liverpool, 19,022; Severn ports, 22,329; and Scotch ports, 952 tons. The total exports of coal from January to August, inclusive of the present year, amount to 4,935,705 tons, showing a decrease of 22,688 tons as compared with the shipments of the corresponding period of last year. Of the exports this year France has taken 858,584 tons; Germany, 441,307 tons; and the East Indies, 385,714 tons.

The anchorage for one set of chains for the Clifton Suspension Bridge is now complete, and the work of hanging the links will be at once commenced, thus exhibiting a perceptible progress. Great hopes are entertained that the bridge may be completed by June next, in which month the meeting of the Bath and West of England Agricultural Society will be held at Bristol, at which his Royal Highness the Prince of Wales, who has accepted the office of patron, is expected to be present. If, however, the work should not be finished by that time, there is little reason to doubt that it will be accomplished by September, 1864, in which month the British Association will assemble at Bath, and the completion of the bridge—the foundation of which was laid by the Marquis of Northampton, a former President of the Association, so far back as the year 1837, on the occasion of the visit of the Association to Bristol—might then be fitly inaugurated.

The second trial of the iron-plated screw steamship "Prince Consort," 35 guns, 4,045 tons, which took place at Plymouth, on Thursday, was considered satisfactory. The mean speed attained in six runs was 13·132. The trial was at full boiler power. Both the engines and boilers worked exceedingly well, and although in some of the runs the wind freshened from an average of 3½ up to 5, it appeared to have very little effect on the speed of the vessel.

The Agricultural Society of Suffolk have adopted a resolution under which the association recommends the appointment of a competent engineer as inspector of agricultural engines. The inspection is proposed to be made at least half-yearly at a certain fixed payment per engine for each examination, the charge to be paid, with the exception of a small annual grant from the funds of the association, by the owners of the engines. The inspector will be required to keep a registry of all engines inspected by him from time to time, with the name of the makers, the date or age of the engine, and the limited amount of pressure in pounds to the square inch upon the boiler—all of which is to be painted in large and legible letters upon the engine. The inspector is also to examine every engine-driver as to his fitness, and, if satisfied with him, to give him a certificate which will enable him to wear a badge on his right arm, having a number upon it corresponding with the inspector's book. This badge or distinction the driver is to be obliged to wear when at work with his engine. The inspector is also once a year to make out a schedule of all engines examined by him, with a report upon their condition, together with any suggestion which may occur to him in the course of his inspection.

The division of iron-plated vessels collected at Cherbourg was to have put to sea on Sunday afternoon. It is to double the Isle of Ushant and steer towards the coasts of Spain. The first cruize is to last for from twelve days to a fortnight without anchoring. Vice-Admiral Penaud, president of the commission charged to watch the experiments, hoists his flag on board the "Solferino." The other members of the commission are distributed among the four frigates, which, with the "Solferino," form the division. There are the "Couronne," the "Magenta," the "Invincible," and the "Normandie." The steam advice-boat "Talisman" is placed at the disposal of the vice-admiral for the service of the division during the whole course of the experiments.

We have heard with regret of the death, after a protracted illness, of William Buckle, Esq., Assistant Coiner of the Royal Mint. That gentleman was widely known in the mechanical and engineering world; and the respect in which he was held was as extensive as was his acquaintanceship with members of those professions. Mr. Buckle was, for more than thirty years, manager of the Soho Works, for Messrs. Boulton and Watt; but during the past twelve years he had occupied the post above named. The death of the lamented gentleman took place at the Mint, on the 30th ult.

Shaver's patent eraser is an extremely ingenious little instrument, recently brought under our notice, containing a burnisher, paper-cutter, folder, and pencil in a neat and elegant form. It is decidedly the best thing of its kind.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 512.
Boilers and Furnaces—*none*.

491. R. Martindale. *Improvements in lamps and burners, and in apparatus employed for milling or ornamenting parts of lamps, which apparatus may also be applied to other similar uses.* Dated February 23, 1863.

This invention consists—1, of improvements in the construction of oil, hydro carbon, and other similar lamps, and burners used for other purposes than lamps, of the description in which a flat cotton can be employed to form a cylindrical wick by the following means:—The patentee alters the form of the wick case, which is usually a circular tube, and makes it either flat or semi-annular at its lower end, and merging into a circular tube or cylinder above. An inner tube around which the wick is arranged reaches slightly below the shoulder of the outer tube or wick case, that is to say, slightly below the point at which the flat or semi-annular portion meets the circular part. This inner tube serves as a guide to the cotton, and causes it to assume a tubular form; or, by the employment of a suitable guide or funnel, he can insert these flat wicks at the top of the wick case and wind them down the tube into their proper position. The winding these wicks he effects by employing a thumb button and series of toothed wheels and rollers which serve to maintain the vertical position of the cotton; or he can employ a cotton holder and cap worked up by means of a slide, or by a lever or a series of wheels, as above described for the purpose of raising the wick; or it may be done by means of a cap working up a slot or groove in the inside of the wick case. 2, The invention consists of improvements applicable to gas as well as other descriptions of burners. He surrounds the burner with one or more air chambers or cones, each separated from the other by its own windguard, by which arrangement more perfect combustion is insured, and a smokeless or nearly smokeless flame is obtained. 3, The invention consists of improvements in apparatus to be employed in milling or ornamenting parts of lamps, which apparatus may also be applied to other similar uses. In place of the chock of an ordinary lathe, he inserts a block piece or holder to receive the stamped or shell work to be milled. In front of this holder he fixes upon a jointed arm in a rest a lever rod, forked at one end to hold a revolving wheel or roller engraved with the pattern or mill; the shell or stamped work being fixed upon the holder, the operator by a motion of the lever rod brings the milling roller into contact with the shell, and thus the pattern or milling is produced upon the shell. If a pattern or mill be required upon the interior of the shell also, the holder in the lathe is engraved with a pattern. For solids, such as thumb buttons, screws, and other like articles, a very slight modification of the form of the holder, or the use of clams, will allow of their being similarly milled or ornamented. *Patent completed.*

492. T. R. Harding. *Improvements in carding and combing flax, wool, cotton, and other fibrous substances.* Dated February 23, 1863.

This invention relates to the application of drawing-off rollers or other similar apparatus to cylinders covered with teeth or other carding surface for the purpose of drawing-off and separating the longer and more valuable portion of the material under operation, both from that portion which is shorter in the fibre, and partakes more of the nature of noil, and also from all impurities and refuse. *Patent completed.*

493. T. and A. L. Dickens and H. Heywood. *Improvements in ornamenting plush and other such textile fabrics.* Dated February 21, 1863.

This invention relates to those fabrics which, after the manner of woollen or other plush, are provided with loose, floated, or raised fibres produced either during the process of weaving, or by a subsequent process, such as "raising." These fabrics the patentees dye by the usual operations, and then protect any desired portions thereof, so that they will resist a further application of dyeing or printing materials. The surface is then brushed over, or is otherwise treated with a colouring matter, whereby the face or raised fibres are tinted, leaving the back or groundwork with its original tint; the prohibited portions, however, not having been submitted to the secondly named dyeing process, afford the desired pattern. *Patent completed.*

494. J. Tatham. *Improvements in machinery or apparatus for preparing cotton and other fibrous materials for spinning.* Dated February 23, 1863.

This invention relates—1, to the drawing frame, and consists in a method of driving the coilers thereof. For this purpose the patentee places the line shaft above the carrier wheels which impart motion to the said coilers; and in order to enable him to adopt this arrangement, he forms the beam which supports the stands or slides so that the top thereof extends partly only between the front and back portions of the said beam. Another part of the invention relates to feed rollers of preparing machinery, and consists in so disposing them that the fibrous material is caused to lap around one or more of their surfaces. Another part of the invention relates to the slubbing frame, and consists in conducting the material after it leaves the delivering rollers, and before it reaches the floor, through a trumpet or guide, whereby the said sliver is brought into a cylindrical form. *Patent completed.*

495. J. Erwood. *Improvements in producing imitation gilding on paper-hangings and other surfaces, also in metal leaf and metallic or bronze powder suitable for the purpose.* Dated February 23, 1863.

In producing imitation gilding on paper-hangings and other surfaces it is now common to employ a metallic leaf known as Dutch metal, and a metal powder or finely divided leaf called bronze powder is also made use of; these both, however, lose their brightness in a short time. According to this invention, the inventor employs in place of these materials a metallic leaf prepared from gold coloured alloys of copper and aluminium (he uses about 10 parts of aluminium and 90 parts of copper) by rolling, annealing, and beating the said alloy, and he applies the said leaf to the paper or surface to receive the imitation gilding in the same manner as that in which Dutch metal is commonly applied. He also employs for the same purpose a metallic powder made from the same material, and this he applies in the same manner as that in which ordinary bronze powder is commonly applied. In producing the metallic leaf from the alloy of copper and aluminium, he employs the processes now adopted for making Dutch metal; and in producing the improved bronze powder from the alloy of copper and aluminium, he employs the processes of rolling, beating, stamping, and grinding, as is practised in making ordinary bronze powder. *Patent abandoned.*

496. H. Masters. *Improvements in spools, bobbins, rollers, and similar articles.* Dated February 24, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

497. D. Spink. *Improvements in the construction and arrangement of armour plates for ships.* Dated February 24, 1863.

In carrying this invention into effect, plates or bars of wrought iron, steel, or other material adapted for the purpose, are placed with their edges outwards, such plates or bars having projections formed thereon out of the plates or bars themselves, so as to constitute an armour of great strength. The plates or bars are connected tightly together by means of large bolts passing through the sides thereof, such bolts also serving by means of small eyebolts through which the former pass to secure the armour to the hull of the ship. *Patent abandoned.*

498. W. and H. Whitehead and H. Barber. *Improvements in the manufacture and securing of cutlery handles, and machinery employed therein.* Dated February 24, 1863.

This invention is not described apart from the drawings. *Patent completed.*

499. J. Clay. *Improvements in the manufacture of saddles.* Dated February 24, 1863.

In making the pads and rolls and the upper leather according to this invention, the patentee takes a pair of moulds having internally the figure which it is wished to give the upper leather, that is to say, having the figure of the saddle with its projections. He wets the leather and places it upon the lower or convex mould, the wetted leather being held and compressed between the two moulds. The leather is allowed to become dry in the moulds, and when dry it is removed from the said moulds, and the hollow portions having the figures of pads or rolls, are filled with stuffing. The said upper leather having the pads and rolls thus made in it is secured to the stout leather called the shield or under-flap and skirt in the usual manner. Where it is wished to ornament the saddle by embossed or raised ornaments, they may be made at the same time, and in the same manner, as the rolls and pads. The whole of the upper leather, that is to say, that covering the flaps, skirt, and seat of the saddle may be made together with the required pads, rolls, and ornaments from one piece of leather; or the pads may be made of two or more pieces, as in the ordinary way. *Patent completed.*.

500. J. Hawthorn. *Certain improvements in handles for doors, drawers, and other means of enclosure.* Dated February 24, 1863.

This invention relates to the manufacture of such handles or knobs for doors, drawers, &c., as are made of china, clay, earthenware, and other argillaceous substances, and is designed for the purpose of combining a screw therewith in such a manner that it may have a secure hold in the handle, the projecting part of such screw being the means of attaching the handle or knob to the door or drawer. The improvements consist in the employment and use of a metal male screw fitting into a female screw tapped on the handle or knob, and so secured therein; such combination forming a more perfect connection between the metal and earthenware than hitherto attained. The opposite end of the piece of metal is also screwed, by which means the handle is secured to the door or drawer. *Patent completed.*

501. G. Davies. *An improvement in melting and smelting furnaces.* (A communication.) Dated February 24, 1863.

This invention consists in applying to a foundry, cupola, or other furnace (substantially in the manner described) a box of any suitable form, having an opening through which may be discharged the slag or scoria which flows into the box from the furnace through another opening, and through which the molten metal—which also passes from the furnace into the box—may flow from the latter. The object of this invention is to obviate the difficulties which arise from an accumulation of undue quantities of slag or scoria in melting and smelting furnaces. *Patent completed.*

502. W. E. Gedge. *Improvements in the manufacture of hats.* (A communication.) Dated February 24, 1863.

The hat body, according to this invention, is made of silk stuff thoroughly steeped in an impervious preparation or stiffening composed of gum lac and gum elemi dissolved in about equal proportions of spirits of wine, and after the body has been stretched on a suitable frame, any impurity or shade left by the stiffening washed off, and the glossiness of the stuff restored, the tip and brim are then cut and placed on the form, a strip of gauze only being used as a band where the junction of the plush is to be made. Varnish or other coating is then placed on the hat body, and any suitable material (usually silk plush) is glued over all. *Patent abandoned.*

503. J. W. Burton. *Improvements in the bearings and leashes of axles and shafts.* Dated February 24, 1863.

In carrying out this invention, the bearing or part on or against which the axle or shaft works is composed of glass, or other similar hard and smooth material or composition, and the flanges or ends or outer parts are composed of brass, or other suitable metal or alloy, and there is inserted between the said bearing and the flanges or ends pieces of wood, papier mache, felt, india-rubner cloth, or other similar non-metallic and partially elastic substance or material. The several parts are united as required by means of counter-sunk bolts, or in any other convenient manner. *Patent completed.*

504. J. Le Butt. *Improvements in machinery for dressing grain.* Dated February 24, 1863.

In place of employing flat screens, the inventor constructs screens in such manner that every alternate wire of the screen may either be stationary whilst the other wires are moved to and fro, or may be moved in the opposite direction to them. By constructing screens in this manner, the spaces between the wires will not have to be kept clear by means of discs or other instruments. When the screen is composed of a set of moveable wires and a set of stationary wires, the frame which carries the moveable wires may be carried by rollers running on inclined rails, and the frame may have the to-and-fro motion imparted to it by a crank or otherwise. The inventor, however, prefers to carry the moveable frame by means of upright springs of wood, or other material; there being, by preference, two springs on each side of the frame. When both sets of wires have a to-and-fro motion imparted to them, one set being moved in one direction whilst the other set moves in a contrary direction, he prefers to carry the frames of each set of wires by springs, as just described, but they may be otherwise carried. *Patent abandoned.*

505. W. Hooper. *Improvements in insulating and protecting telegraphic and other wires and rods, and in machinery connected therewith.* Dated February 24, 1863.

When covering and protecting telegraphic and other wires and rods with india rubber or compounds of india rubber, the patentee obtains the tapes or narrow strips to be employed by cutting a continuous sheet of india rubber or compound of india rubber from a block of the material caused to rotate in front of a knife, and afterwards he divides this sheet into tapes or narrow strips by a series of cutting edges, the interval between which is the width of tape required. He applies these tapes to the wire or rod by lapping it around the same, as heretofore practised. India rubber and sulphur (or a substance having a similar action), combined, by preference, with tar or any of the articles usually employed with india rubber and sulphur, may be cut into tapes or narrow strips, and applied as above described, and he vulcanizes the same by the well-known methods of vulcanizing after the wires or rods are coated. He varnishes such sheets, tapes, or strips of india rubber or india-rubber compound to keep them from adhering together, and also to prevent them taking up dust or dirt that may come in contact with them, or absorbing moisture from the atmosphere. This varnish may be composed of half a pound of shellac, half a gallon of water, and two or three fluid ounces of strong liquid ammonia. When only one side of a sheet is varnished, a small quantity of colouring matter is mixed with the varnish to show on which side of the sheet or tape the varnish has been applied. Before coating the wires or rods with the tapes or strips, he submits the latter to a uniform temperature (he prefers about 60 deg. Fahrenheit), to cool them in the summer, or to warm them in the winter, as the case may be, by which means, when they are lapped on the wires or rods, or passed through discs to coat the same, they will work more accurately than heretofore when the tapes or strips have been applied without regard to temperature, which has given rise to unequal suppleness, and, as a consequence, eccentricity of the conductor. *Patent completed.*

506. D. B. Chatterton. *Improved brick-making machine.* Dated February 24, 1863.

In carrying out this invention, the inventor employs a shaft which, upon power being applied thereto, gives motion to a pinion, to a bevel pinion which acts on a spur wheel, to another bevel wheel, thereby giving motion to another shaft with other bevel wheels, and to a screw placed in a hopper or feeding tube, by which the clay placed therein will be forced into moulds arranged in a circular, or approximately circular, frame. The spur wheel aforesaid will likewise give motion to a crank or eccentric, and, by endless band or cord, to a pulley working the delivery band or apron hereafter described. The crank acts on a lever carrying at its end a stamp mould. The eccentric has a rod attached, terminating in a pall working on the face of a pall wheel, which gives motion to the circular mould frame aforesaid. The hopper being filled with clay, and the machine being put in motion, the screw is caused to force the clay into the moulds, the pall acting on the pall wheel moving the moulds partly round, and bringing a mould under the press or stamp, the stamp being forced into this mould and moulding the brick; on its being withdrawn by the backward action of the crank, the pall moves the mould frame another part of a circle, the clay in the meanwhile having been forced into the next mould, the lever pressing the brick as before. The circular frame being forced round, brings the loose

bottom of the moulds to bear on the top of the eccentric keyed fast on the fixed shaft, and forces the loose bottom a portion of the way out, and the moulded brick with it, and so on until the brick falls on the endless band or apron prepared for that purpose, worked by the pulley which moves the brick, until it is taken from the band. After the brick is forced out of the mould, the eccentric acts on a roller and forces the loose bottom back to its place, so that the mould can again be filled at the feeding tube or hopper. *Patent abandoned.*

507. E. R. Walker. *Improvements in valves, and in apparatus connected therewith.* Dated February 24, 1863.

The patentee claims—1, the method of reducing the friction on the surface of the slide valves by means of a flexible plate or plates of whatever form attached to the valve, and against which the steam or fluid presses, so arranged that this pressure against the plate neutralizes or tends to neutralize the pressure against the valve, as before described; 2, the method of reducing the friction on the surface of slide valves, by means of a plate or plates covering an open-backed valve, and attached to the flexible plate, as before described. *Patent completed.*

508. H. B. Willson. *Improvements in the construction of war and merchant ships.* Dated February 24, 1863.

The main object of this invention is so to construct war and merchant vessels that, although built of large capacity, they shall be able to navigate shallow waters and obtain high speed with moderate power. The following are some of the important features of the invention. The inventor forms the hull of the vessel in midship cross section of a figure approaching that of a parallelogram, the lower immersed angles being rounded off to mitigate resistance, and the more ready to reflect wave undulations, and for the same reason he also curves the bottom or floor downwards from a few feet on each side of the keel, which thus becomes enclosed inside the ship's skin from end to end. The rest of the floor is made long and level to give buoyancy and prevent the ship from pitching deeply into the seas. This enables him to give a finer entrance and run, which he prefers to be slightly hollowed to lessen resistance. The longitudinal as well as the general strength of the ship he secures by carrying a central wall constructed in the same manner as the side walls from the keel, to which it is fastened at all points up to the main deck, so far fore and aft as may be necessary to obtain adequate strength; and in cases where the necessary stiffness cannot be thus gained, he springs an arch nearly from one end of the vessel to the other, so as to make it constitute a part of the structure of the central wall, which arch may be carried above the upper deck in merchant vessels to such height as may seem needful. This central wall also adds security to the ship by dividing it into two longitudinal and equal water-tight compartments. The transverse girders extend from either side the vessel's framing, to the central wall or great longitudinal girders, and are firmly secured thereto, by which means the central wall or girder remains unbroken and unimpaired in strength. *Patent completed.*

509. G. A. Huddart. *Improved means of imparting heat to fluids.* Dated February 24, 1863.

The chief object of this invention is to facilitate the raising of steam in steam boilers. This the inventor proposes to effect by partially filling the water space with a good heat-conducting material, such as solid or hollow pieces of iron of various shapes, which when thrown into a steam boiler, will so arrange themselves as to form a kind of porous filling that will not interfere with the circulation of the water, but will occupy a considerable portion of the water space. *Patent abandoned.*

510. A. Junger. *An improved life-preserving garment.* Dated February 24, 1863.

This invention consists in constructing a garment in the shape of a cape coat, so cut and padded with ground cork or cork shavings, or other like suitable buoyant materials, that, on a person wearing it entering or falling into sea-water, he shall be supported in a vertical position with his body from the waist upwards out of the water. In other than sea water the body would sink some few inches deeper. *Patent completed.*

511. T. Mallinson and J. Livingston. *Improvements in throstle spinning and doubling frames, wholly or partly applicable to roving and slubbing frames.* Dated February 24, 1863.

This invention refers to machines for spinning and doubling of the character of the throstle frame, and also wholly or partly applicable to roving and slubbing frames, and its main object is an improved arrangement and construction of parts with a view to a more perfect lubrication of the bearings of the spindles of such machines. The invention consists in constructing the footsteps for the spindles by a part which resembles a thimble in form, or a tube closed at one end, which is made, by preference, of cast iron, and in the hollow of this thimble part a piece of brass is inserted, so that a cavity is left between two sides and the bottom of the brass and the interior sides and bottom of the thimble part. The brass has a hole drilled through it for the foot of the spindle to pass through, which rests on the bottom of the thimble part, which is secured in the spindle rail by a set screw, the same as the ordinary footstep. With this arrangement, the lubricating matter is filled into the cavity formed between the brass and interior of the thimble part, and by the rotation of the spindle a constant circulation of the lubricating matter is maintained, as the oil passes from the bottom of the cavity up the centre, and descends to the bottom of the cavity down the sides. The invention further consists in making the moveable spindle rails with a cavity in the upper side of the rail to give space around and above the collar (which is screwed into the rail) for lubricating matter and a washer or strip of fibrous material, the "washer" or "strip" being provided with holes, so as to pass on to the spindle. *Patent abandoned.*

512. R. W. Thompson. *Improvements in obtaining and applying motive power, which improvements or parts thereof are applicable for raising, forcing, and measuring fluids.* Dated February 24, 1863.

This invention relates in the main to the arrangement and construction of an improved rotary steam-engine, which consists of a cylinder or steam chamber with a horizontal axis containing within it two diaphragms or pistons. One of these pistons or diaphrams is keyed upon a solid shaft passing through the axial line of the cylinder, whilst the other is similarly keyed upon or attached to a tubular or hollow shaft, through which the solid shaft is passed. The hollow or tubular shaft passes out of one end of the steam cylinder by a shifting box in the ordinary manner, and the solid shaft passes through it. Each shaft has keyed upon it a working crank, and these two cranks have connecting rods, the opposite ends of which are jointed to the rim of a fly-wheel, disposed eccentrically as regards the steam cylinder by means of suitable joint studs. The positions of the pistons accord with those of the external cranks, and the actuating steam is admitted to one side of the pistons or diaphragms and discharged on the other by valves of any suitable form. At the "dead point" of the engine the two pistons or diaphragms themselves close the steam cylinder ports. If, now, the fly-wheel moves round, one piston will pass the induction port, and the other will pass the eduction port, both moving in the same direction. But when steam enters by the induction port, it tends to cause the two pistons to move in opposite directions. But as the two pistons are set to revolve upon one main centre, and are connected by the cranks and connecting-rods with the fly-wheel, as hereinbefore referred to, working upon a separate and independent centre, it follows that the front or first piston will increase in velocity, whilst the opposite or second piston decreases in speed, the steam being introduced between the two. The result is that, during a complete revolution of the fly-wheel, each of the pistons will traverse three-quarters of a revolution with the actuating steam pressure, and one-quarter of a revolution against it, giving together a working traverse equal to one and a half revolutions. During this amount of traverse each of the pistons is working through a quarter of a revolution against the pressure of the steam, and this, being deducted from the amount of forward motion, leaves a complete revolution of the piston corresponding to that of the fly-wheel with the pressure of the steam available as power. *Patent completed.*

513. G. Bower and W. Hollinshead. *Improvements in apparatus for the production and transmission of gas or other fluids.* Dated February 24, 1863.

This invention consists in constructing dry centre valves used for the transmission of fluid, gaseous, and liquid bodies through a series of four or more separate vessels, in such a manner as to enable the gas or liquid to be conducted through any one, two, three, four, or more of such vessels, but more particularly the application of such valves to the changing of a current of gas in any direction, so as to cause it to pass through any desired number of a series of four or more purifiers. Also in combining with one or more of the various parts of apparatus required for the cooling, cleansing, and purifying of gas, embracing such as are technically called the hydraulic main, scrubber, washer, and purifiers, with a dry centre valve, or a dry centre valve and by-pass valve or valves, so that the combination, in whatever form it may exist, shall enable as desired one, two, three, or more purifiers to be in operation at one time, with power also to pass or shut off the gas from any part which may require the gas to be excluded from it, the whole being within the limits of a single base. *Patent completed.*

514. W. Clark. *Improvements in sewing machines.* (A communication.) Dated February 25, 1863.

This invention consists in certain novel devices for extending the loops of the upper or needle thread on the under side of back of the cloth, or other material to be sewed, and carrying the under or locking thread through them; also in a novel mode of combining the needle-operating lever with the said devices for extending the loops of the needle-thread, and carrying the locking-thread through them, whereby the operation of the said device is produced by the same crank or its equivalent by which the movement of the needle-operating lever is produced; also in a novel construction and arrangement of the feeding apparatus for feeding the cloth or other materials in all directions, and in a novel mode of applying the needle in combination with such feeding apparatus to keep the planes of revolution of the feed-wheel always at the same distance from the line of motion of the needle; also in an improved take-up for drawing back through the cloth or other material the slack of the loops of the needle-thread; and, further, in an improvement in the tension device for producing and regulating the tension on the upper or needle-thread. The invention cannot be described without reference to the drawings. *Patent completed.*

515. W. H. Lapthorn. *Improvements in reefing and furling ships' square sails.* Dated February 24, 1863.

These improvements in reefing square sails consist mainly in the application of cords or ropes to the upper part of the sail, which descend from the yard, and are rove through thimble loops worked on to the reef bands. *Patent abandoned.*

516. H. Wilde. *Improvements in electro-magnetic machines.* Dated February 25, 1863.

This invention consists in improvements in the transmitting instruments described in the specification of letters patent granted to the present patentee on the 8th day of April, and on the 10th day of August, 1861, and numbered 858 and 1994 respectively. In the specification of these patents transmitting instruments are shown and described in which the armature of a magneto-electric machine is mechanically geared with a radial arm, which travels beneath a series of finger-keys, any one of which being depressed, arrests the motion of the radial arm, and also the motion of the armature with which it is mechanically connected. In the present improvement the alternately inverted currents (or currents passing in opposite directions) generated during the continuous revolution of the armature of a magneto-electric machine are made to pass in one and the same direction by means of a commutator or current-changer of the ordinary construction placed on the armature or other axis connected with the ends of the wires in which the currents are generated. These direct currents are then transferred by means of wires to another commutator, by which the currents are again inverted previous to their passing into the telegraphic circuit. This last-mentioned commutator is made to revolve more slowly than the other, so as to allow a greater number of the direct currents from the first-mentioned commutator to pass into the telegraphic circuit before the currents are again inverted. From the relation which the more slowly moving commutator bears to the more quickly moving commutator of the magneto-electric machine, the patentee calls it a differential commutator. This differential commutator is fixed on the axis which carries the radial arm and index finger of the transmitting instrument, or other axis geared with it, and is so constructed as to invert the direct current from the other commutator as many times as there are letters or signs on the dial of the indicating instrument. *Patent completed.*

517. F. A. Gatty. *Improvements in printing and dyeing cotton and other fabrics.* Dated February 25, 1863.

This invention consists in producing a black colour, either in combination with other colours or alone, on cotton and other fabrics, in the following manner:—When the fabrics are intended to be prepared with mordant for dyeing, the patentee takes acetate of alumina (commonly called red liquor) at 10 degs. of Twaddle's hydrometer, and dissolves in it eight ounces of bi-chromate of potash to every gallon of acetate of alumina. Any other soluble chromate will answer the purpose, but he prefers to use the bi-chromate of potash. He then pads or otherwise impregnates the cotton or other fabrics with the said mixture of acetate of alumina and bi-chromate of potash, and dries them. They are then printed with a thickened solution of a salt of aniline or other similar tar products. He finds the following proportions to answer best: One gallon of water is thickened with one pound of starch, or other suitable thickening substance, and when cold he adds one pound of aniline, previously mixed with one pound and a quarter of muriatic acid of commerce, and one pound of water. Although he prefers to use muriatic acid, various other acids will answer the same purpose. After the fabrics have been printed, they are treated in the same way as mordanted fabrics which are intended to be dyed with madder, garancine, or other colouring matters. *Patent completed.*

518. R. Maynard. *Improvements in portable chaff-cutting machines.* Dated February 25, 1863.

This invention has reference to a previous patent dated 3rd March, 1856, and consists in connecting to portable chaff-engines an elevator to convey the chaff sufficiently high for it to fall into a bag or other vessel suitable for carrying it away, instead of, as heretofore, permitting it to remain on the floor to be gathered up by hand. For this purpose the patentee conducts the chaff by an incline, or by any other suitable means, to a revolving fan, which is driven at a sufficient velocity to cause the chaff to ascend to the height required. Or to affect the same purpose, he employs an endless chain or band, to which is attached buckets or other projecting parts, and the same being passed over a revolving drum carries the chaff with it. Or he uses any other kind of elevator which, in practice, he may find suitable. *Patent completed.*

519. R. A. Brooman. *Improvements in lamps for burning petroleum and other similar oils, and in feeders or cans for supplying such oil to lamps.* (A communication.) Dated February 25, 1863.

This invention is carried out as follows:—The inventor covers the glass or other reservoir with a cap having a circular hole in the centre, to the sides of which aperture a ring with screw threads is fixed. This cap is dished round a portion of its surface, and apertures for the passage of the liquid are made through the bottom of the dish. A crown is fixed on this cap in such a manner as to be capable of being turned; it is solid with the exception of a slot or hole made in it. When the slot or hole is brought over the dished portion of the cap, passage for the liquid to supply the reservoir is opened. When the crown is turned so far round as to bring the aperture in the crown over the solid part of the cap, communication with the interior is shut off, and loss by evaporation through the supply aperture prevented. The feeder or can is provided with a two-way cock, opening into a nozzle, and communicating with the interior of the can when it is held in a position for pouring out its contents, but when the can is in any other position, the nozzle falls, and communication through the cock is thereby shut off. The gallery and upper parts of the lamp are fixed in the ring before mentioned by a solid plug, from which the gallery springs, being screwed into it. The plug is pierced through the centre to receive a tubular wick-holder; a sheath is fixed outside this wick-holder, the edges of which are turned down at top over and upon the sheath, and thus the sheath and tube are held together. The tube is fixed to the under side of the plug by means of flanges carried out from the bottom of the tube, and slots are made in the wick-holder and sheath for the reception of two spiked wheels fixed on an axis on which a button is fixed, and extending beyond the gallery for turning the wick up and down. The capsule or cap through which the wick passes is formed in a piece with a tube and a ring, the former for carrying the lamp chimney, and the other the globe, both resting upon the upper part of the gallery; the sides of the gallery are open, and a plate of wire gauze or perforated metal for dividing the air before passing into the capsule is supported by a flange on the inside of the gallery. *Patent completed.*

520. J. Fitter. *An improvement or improvements in the construction of castors for tables, chairs, and other furniture or other articles.* Dated February 25, 1863.

This invention consists in the arrangement of anti-friction rollers within an inclined circular groove formed round the under side of the castor socket, or round the under side

of the plate upon which the article to be moved is intended to rest. *Patent completed.*

521. W. READMAN. *Improvements in the manufacture of carbonate of magnesia, and of iodine and kelp salt, and other products from kelp.* Dated February 25, 1863.

By this invention the carbonate, whether in the ley or in the salts deposited from the ley during evaporation, is utilized in the manufacture of carbonate of magnesia from bittern, being the residual liquor derived from the manufacture of common salt, or from a solution of chloride of magnesium. The ley, or a solution of salts containing the carbonate derived from the kelp, is mixed with the solution of chloride of magnesium, the products from which are carbonate of magnesia and chloride of sodium. A portion of soda ash or other similar carbonate may be added. The resulting liquor and washings are evaporated in suitable vessels, and the soda and potash, as well as the iodine and bromine, are recovered in the ordinary manner. *Patent completed.*

522. E. B. WILSON. *An improvement or improvements in the manufacture of an alloy or alloys of titanium and iron.* Dated February 25, 1863.

We cannot give space to the details of this invention. *Patent abandoned.*

523. J. B. GREEN. *Improvements in the manufacture of paper.* Dated February 25, 1863.

Here the wire mould on which the pulp is spread is formed with certain portions of its surface in grooves or channels, so as to be capable of receiving a greater depth of pulp at such portions. By this means, an increased thickening or density of the paper is produced at those parts which correspond with the grooves or channels in the surface of the mould. *Patent abandoned.*

524. R. LAWRENCE and W. NIBLETT. *Improvements in apparatus for regulating the flow of gas for purposes of illumination.* Dated February 25, 1863.

This invention consists in placing over and upon the ordinary gas-burner a tube or cylinder of any suitable metal or other material, fitted at the top with an adjustable cap, piston, or plug. The slits or apertures for the escape of the gas are cut either in the cap, piston, or plug, or in the tube or cylinder. The objects of the invention are, in the first place, to admit the gas from the ordinary burner into a chamber for the purpose of allowing it to expand, thereby reducing its pressure; and, secondly, by the proper adjustment of the cap, piston, or plug, to allow the gas to escape through the slits or apertures at that pressure which is most desirable to produce complete combustion, and to develop the illuminating powers of the gas to the greatest possible extent. *Patent completed.*

525. J. GAILEY. *Improvements in apparatus for the purpose of supplying air for mixture with gases and other aeriform fluids.* Dated February 25, 1863.

This invention consists in the use of two chambers or receivers similar to gas holders, that is to say, they are chambers inverted and open at bottom, and dipping into outer casings containing water or other fluid, which inverted chambers have alternate up-and-down reciprocating motion imparted to them. The interior of such chambers, have air inlet and outlet communications—the inlet being controlled by suitable valves to permit the ingress, but to prevent the egress of the air; while the outlet passages are similarly furnished with valves to permit the egress of air, but to prevent the ingress. Those outlet passages communicate with a reservoir to contain the supply of air furnished, from whence it may be drawn for the purposes required. A safety or pressure valve may be applied to this reservoir to regulate or limit the pressure of air therein. The inventor communicates motion to the reciprocating chambers by means of a spring train, or it may be a weight, a slight pressure and a small quantity of air only being required for the purposes to which he applies the apparatus. In connection with the train of wheels, he uses what is known as the mangle motion, which, although the train always moves continuously in one direction, a reciprocating rotary motion is communicated to a wheel by reason of the pinion communicating the motion from the train gearing with a segment of teeth alternately on the inside and then on the outside of the periphery of such segment, as is well understood. To the wheel so actuated he attaches a rope or chain, from the ends of which the inverted chambers are suspended, and by which the reciprocating rotary motion of the mangle wheel imparts a slow up-and-down motion to the inverted chambers, and so forcing a supply of air. *Patent abandoned.*

526. J. EDWARDS. *Improvements in the manufacture of buttons.* Dated February 25, 1863.

This invention consists in fixing the colour of what are termed gilt buttons by an application of silver varnish, or any other suitable varnish or liquid. This varnish protects the gilding from the action of the atmosphere or sea air, and is applied the same way as lacquer. *Patent abandoned.*

527. H. H. HENSON. *Improvements in mats.* Dated February 25, 1863.

One part of this invention consists in first forming oval and other shaped strands of cocoa-nut fibre, or other similar fibrous materials, or mixture of such materials, by inserting into them a core of thin japanned or painted metal or wood, cane, or other suitable material, and then constructing mats of these strands, by preference, in such a manner that the strands being placed on edge, and some of them being made wider than others, such strands are raised above the general level of the mat, so as to produce an uneven surface, and thus render the mats more efficacious as scrapers for removing the dirt from the boots. Another part of the invention consists in providing the ordinary fibrous mats with a waterproof backing, treated with any suitable waterproof material or compound in any stage of the manufacture, or afterwards, to prevent the same from being so readily saturated with moisture as at present, and thereby preserving it from decay. Another part of the invention consists in constructing mats the wearing surfaces of which are formed into two or more subdivisions, one or more of which has or have a fibrous pile surface, whilst the other or others is or are formed of an open or cellular structure flush with the pile, composed either of fibrous strands, india rubber, or its compounds or equivalents, or metal, thus combining the properties of a brush and a scraper in one and the same mat. Another part of the invention consists in constructing mats of any description with a removeable centre piece, so that when a centre piece is worn out it may be removed and replaced by a new one. Another part of the invention has reference to the manufacture of cellular india-rubber mats generally. *Patent completed.*

528. T. V. LEE. *Improvements in machinery for digging, compressing, and moulding peat or turf, and for retorts and kilns for drying peat or turf, and making peat or turf charcoal through the agency of hydro-caloric or superheated steam, and for collecting the products of distillation whilst charring the peat or turf.* Dated February 25, 1863.

This invention has for its object the preparation of peat or turf for smelting ores, for generating steam in marine and locomotive boilers, and for domestic uses, in a more economical and expeditious manner than any heretofore practised, and comprises, among others, the following features:—For digging peat the patentee employs a machine consisting of a revolving shaft carrying one or more series of spades set at suitable angles. This shaft is mounted in bearings, and rotary motion is given to it by the united action of toothed-gearing, a pair of rocking levers, and eccentric. The levers are connected to a vertical shaft, and each series of spades is brought into action alternately, and as each series takes up and delivers to a hand-barrow or other receptacle its number of sods or spits, drums or wheels on which the machine is mounted, actuated by the ratchet-wheel and eccentric, move the machine backward, and give room for the next series of spades to repeat the operation. That portion of the invention for triturating, compressing, moulding, and perforating peat, and cutting it into blocks of square or other shape, consists of a hopper in which are placed two pairs of rollers horizontally; they are furnished with teeth similar to the well-known bone and rag mill, the first or upper part being set about 4 in. apart, and in its passage between them the fibre of the peat is partially broken, and on reaching the second pair the process of triturating is completed, and a great portion of the water is in this part of the process liberated from the peat and runs off through a slot or perforations in a horizontal cylinder, into which the peat now rendered homogeneous falls. This cylinder is fitted with a shaft on which are affixed knives, arms, or blades which carry the pulp to the exit end, where a propeller forces it through the moulds of any required form. In the moulds are placed iron rods of three-fourths of an inch in diameter for perforating the blocks, and as the mass exudes, a knife is brought into use, and cuts off the blocks the size required. The blocks thus formed are fit to be handled, the process having deprived the peat of one half its water. This portion of the invention is worked by toothed gearing. The blocks formed in the manner described are placed upon carriages and run into retorts or kilns for drying or charring, as may be desired, the kilns being furnished with rail or tramway to correspond with similar rail or tramway outside. *Patent completed.*

529. W. E. NEWTON. *Improvements in producing stereotype plates for printing surfaces.* (A communication.) Dated February 25, 1863.

This invention relates to a means of producing curved plates. To this end the matrix is made on a sheet of steel, or other elastic substance, the normal shape of which is curved. But in order either to cast the stereotype plate, or to form the printing surface, by electro-deposition, the curved plate must be made to assume a flat or straight form by being secured down in any convenient manner to a flat plate, table, or surface. The clay, wax, or other suitable plastic material to form the mould or matrix is then put in the plate, and the impression is taken therein. The elastic plate is then released, when it assumes the curved form, and of course the matrix takes a corresponding form. The matrix or mould is then put on a curved plate or bed, and dried, and the stereotype plate is then cast or formed by electro-deposition. *Patent completed.*

530. W. HUDSON and C. CATLOW. *Improvements in looms for weaving.* Dated February 25, 1863.

This invention refers, firstly, to the motion for making the shed, and to that arrangement thereof in which a revolving tappet is employed acting at its upper and lower sides upon rollers connected to the treadles. According to this invention, the inventors mount these rollers upon an arm through which the tappet shaft passes so as to act as a guide and support for it. This arm is connected at its lower end to a treadle, which is thus caused to vibrate in order to form the shed. As applied to the arrangement above mentioned for making the shed, they cause one treadle to give motion to another by jointing the two together. Another improvement upon the said motion consists in mounting one or both of the rollers acted upon by the tappets upon springs, so as to yield when required. Another part of the invention relates to the beating-up motion, and consists in forming the connecting rod and stay as one rigid part, the latter being jointed to the lathe sword. Another part of the invention relates to the motion for taking up the work or for letting off the warp. For this purpose they use a plain wheel and clip or friction surface, which is brought into action by a lever acting thereon within the diameter of the work or warp beam. *Patent abandoned.*

531. N. THOMPSON. *Improvements in machinery for sawing wood.* Dated February 25, 1863.

In carrying out this invention, when sawing irregular or varying bevels, the patentee employs in front of the saw (which is by preference a band saw) a rotating fence, consisting of a wheel or pulley capable of revolving on an axis level with the surface of the saw bench, and in a line with the saw. Out of this revolving fence a quadrant is cut, and this serves as a guide for the wood to be sawn. In cutting a bevel from a plank or other piece of rectangular section, a line is marked on the upper surface of the wood, where the saw is to cut, and the angle of the piece of timber being laid in the angle of the fence, the cut is commenced, and then by inclining the wood more or less (the revolving fence moving with it) the saw is made to follow the line previously marked. This being done ensures obtaining the requisite bevel supposing the line to have been properly marked, as the fence obliges the saw to cut it out of the wood along the lower angle of the piece. *Patent completed.*

532. J. INGLIS. *Improvements in machinery or apparatus for folding paper and other fabrics or materials.* Dated February 25, 1863.

This invention relates to a system or arrangement of machinery or apparatus to be used for folding sheets of paper and other fabrics or materials, such as newspapers, sheets of paper for book-binding, and for other uses, and is partially based upon an invention of a machine for folding, for which J. Black, of Edinburgh, obtained letters patent in November, 1850. The present improved machine is contained upon and within an open rectangular framework, adjoining which and attached thereto, or forming part thereof, is a feeding table or platform, opposite to which the attendant stands. As each sheet is placed upon this table or platform from the bank or source of supply, a pair of grippers or traversing holders, actuated by the gearing of the machine, come forward and seize the sheet by its two opposite edges. The grippers then return to convey the sheet down from the table to an inclined folding platform attached to or forming part of the main framing. This inclined platform is set at a considerable angle with the horizontal line, and it has along its centre a longitudinal slot for the passage through of the paper during the primary fold. Directly on this slot is a serrated or roughened folding knife or thin lever arm, caused to vibrate back and forward by the main gearing. As the sheet of paper comes over the slot and beneath the folding knife, the grippers relax their hold, and the folder comes down upon the released sheet, forcing it through the slot, and thus producing the primary fold. The folded sheet is then passed beneath the platform, and is then in readiness for being refolded by knives or folding arms arranged at right angles to each other in the framing beneath. Suitable guides or register marks are provided for the due set of the sheet for the gripper action. *Patent completed.*

533. A. MACIVOR. *Improvements veneering or overlaying woods according to two methods—1, by means of steam exhaustion or air pressure; 2, by the employment of electro-magnetism.* Dated February 25, 1863.

This invention consists in two methods of veneering or overlaying wood—1, by means of exhaustion or steam-pressure, or air exhaustion or air pressure; and, 2, by the employment of magnetism. The invention cannot be described without reference to the drawings. *Patent completed.*

535. H. EDMONDS. *Improvements in the ventilation of ships and vessels, and apparatus connected therewith.* Dated February 26, 1863.

This invention consists in the application and adaptation of a system of shafts and air-channels to those parts of a ship's interior where ventilation is necessary, such shafts and air-channels acting directly upon the parts to be ventilated. *Patent completed.*

536. W. H. BROWN. *Improvements in window frames and in glazing windows.* Dated February 26, 1863.

The object of this invention is to render windows—and especially the windows of railway carriages, cabs, and other vehicles—noiseless at all times, and, when closed, dust and water tight. For this purpose the inventor constructs the window frames as follows:—When the outside edge of the sash is intended to slide—as in the case of the stiles of an ordinary sash window—he forms a groove along the outside edge. These grooves fit upon and slide along a beading of vulcanized india rubber, or other suitable fabric, which beading is fixed into the corresponding inner face of the stile of the window frame. Where there is much friction between the groove and the beading, he sometimes lines the groove with pewter or other suitable metal. When the window shuts upon or against the frame as in the case of a common sash window, he forms a similar groove along the edge or the face of the rail or stile, which shuts upon or against a corresponding beading fixed along the frame, upon or against which the window shuts. *Patent abandoned.*

537. C. RITCHIE. *An improved machine for making spiral lighters or spills from wood or other substance, and which machine will make and colour them, when desired, at one process or operation.* Dated February 26, 1863.

This invention consists in the use of a flat wheel or disc mounted on an axle and made to revolve in a suitable framework by means of steam or other power. On one side of the said wheel are fixed several pairs of brackets, each pair being parallel to each other, and capable of receiving and holding between them a piece of thin wood, or other substance, to be operated on and made into spills. Radiating from the centre of the wheel are several screwed rods—viz., one for each piece of wood. The use of the screwed rods is to force or feed the wood outwards towards the periphery of the wheel, and into contact with a skerved cutter or plane, which is there fixed in an adjustable manner to the framework, and so that, while the wheel is moved round, the said cutter will cut a spiral shaving from each piece of wood. On each of the feeding screws is a small cone, and an adjustable stud or projection from the framework comes into contact with the periphery of each cone as the wheel is turned round, and by its friction on the said cone moves the feeding screw round a small space, according to the desired amount of feed. Each feed-screw acts on the wood or other substance to be operated on through the medium of a flat rod of iron, which is doubled into somewhat of the form of a pair of sugar tongs, but having the hands brought nearly into contact, and screwed internally to form a divided nut in which the screw rod acts. This nut is made to close on the rod by means of a small ring removeable by hand when it is required to replace the wood or other material on the machine. *Patent completed.*

538. G. H. LILLEY. *Improvements in apparatus for connecting and securing together planks of wood, applicable to the building and caulking of ships and other vessels.* Dated February 26, 1863.

This invention consists in connecting and securing together planks of wood in the following manner:—As applied to securing the planks of ships, the inventor forms along the top and bottom edges of the planks, lengthwise, holes or apertures, the said holes or apertures in one plank corresponding with those in the other, and into which he inserts right and left-handed screws, the screws at or about their centre having nuts thereon with apertures therein. The material for caulking is led from one screw to the other between the planks, and by inserting levers in the apertures in the nuts, the planks are drawn together, the caulking between the nuts taking into recesses formed in the planks for that purpose, and thus a perfectly water-tight and finish joint is obtained. The material prepared for caulking is vulcanized india rubber, but any other suitable material may be used. *Patent abandoned.*

539. W. A. WILSON and J. SMITH. *Improvements in furnace fire-grates.* Dated February 26, 1863.

This invention relates to a novel arrangement of the parts forming furnace fire-grates, and consists in the use or employment of stationary bars and travelling bars, placed alternately, to form the support for the fuel; such bars, when so arranged, may be distributed either lengthwise or across the furnace. *Patent completed.*

540. A. [illegible]LLO. *An improved method of, and apparatus for, gl[illegible] morocco leather.* Dated February 26, 1860.

We cannot here give space to the details of this invention. *Patent abandoned.*

541. A. P. PRICE. *Improvements in the production and manufacture of blue colours.* (A communication.) Dated February 26, 1833.

This invention consists in the employment of acetates, citrates, succinates, racemates, malates, valerinates, carbolates, benzoates, cinnamates, tartrates, and oxalates of potash, soda, and ammonia in conjunction with aniline and roseine and rose-aniline, in the production of blue colours. *Patent completed.*

542. J. YATES. *Improvements in the manufacture of armour plates or blocks for defensive purposes.* Dated February 26, 1863.

The patentee claims—1, the manufacture of armour plates, blocks, or bars, by hammering, stamping, and squeezing or rolling them in metal moulds or frames of the size and shape of the plate, block, or bar required, substantially as described; 2, the manufacture of armour plates, blocks, or bars, by casting a metal backing on to a wrought-iron face plate or block, as described; 3, the manufacture of armour plates, blocks, or bars by hammering, stamping, or squeezing a wrought-iron plate or block whilst in a welding state on to a cast metal block provided with projections or indentations on its surface, for the more perfectly holding of the wrought-iron plate thereto, as described. *Patent completed.*

543. P. SPENCE. *Improvements in the manufacture of potash, alum, and other salts of potash.* Dated February 26, 1863.

This invention consists in manufacturing potash, alum, and other salts of potsh from those substances which are known as shales of the coal measures. *Patent abandoned.*

544. W. CLARK. *Improvements in the manufacture of buttons, and in apparatus for the same.* (A communication.) Dated February 26, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

545. M. PUDDEFOOT. *Improvements in implements for tilling and cultivating land.* Dated February 26, 1863.

This invention consists in the use of a truncated cone-like piece forming the body of the implement; this is mounted on an axis, and in a suitable frame, so as to turn in a rolling direction while passing over the ground. The frame is furnished with handles to guide it like an ordinary plough, and a beam, shaft, or parts to apply the tractive force. On the cone-piece or body at the large end, the inventor fixes in radial positions what he terms curved coulters or tines, pointed and sharp on the one edge, and thick on the other edge or back; on the other end of the cone-piece he mounts in similar radial positions a series of what he terms shares, being spade-like instruments which are set at an angle to the axis, and so as in revolving to throw the soil on one side, that is, in the direction of the length of the cone axis, and so forms a furrow; one, two, or more rows (in a circular direction) may be applied towards the end of the cone-piece. The implement in rolling over the ground causes the tines or coulters to enter and stir and break up the soil, while at the same time the spades or shares form the furrows. The tine and spades act on different parts of the soil at the same time during one traverse of the implement, loosening and lightening the soil to be operated on in the subsequent traverse by the spades. *Patent abandoned.*

546. J. HUMBY. *Improvements in furnaces and apparatus for manufacturing oxide of zinc or zinc white.* (A communication.) Dated February 26, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

547. R. J. NODDER. *Improvements applicable to hats, caps, helmets, military head-dresses, and other like coverings for the head.* Dated February 26, 1863.

The patentee claims the application to hats and other coverings for the head of a zone or band having the upper portion formed with a warp of metallic wire, or any other material which is non-elastic in the direction of its length, and the lower edge and lower portion and weft thereof of silk, cotton, mohair, or other suitable textile material, in the manner described. *Patent completed.*

548. F. H. TWILLEY. *Improvements in book slides or holders.* Dated February 26, 1862.

This invention consists in certain improvements in the construction of slides or holders for books, whether single or double slides, whereby they may be extended in width in order to hold a considerable number of books, or be reduced so as to contain a few books only, dispensing entirely with all cross-pieces as have heretofore been used. *Patent abandoned.*

549. J. H. ALBINSON and H. H. COCKER. *Improvements in spinning, doubling, throwing, and reeling silk, and in the machinery employed therein.* Dated February 27, 1863.

This invention consists—1, in adapting the usual wrapping machine now employed for testing the size of silk to the English weights and measures reduced to the decimal system, and in applying thereto a balance with a graduated quadrant for indicating the weight and size of the skein produced. The second improvement consists in applying the usual cleaners to the winding frame, thereby performing the operations of cleaning and winding simultaneously. The third improvement consists in the application of the usual throstle doubling and throwing silk threads, either organzine or tram. In order to render the above machine suitable for silk, the patentees apply thereto additional drag-rollers or pulleys for increasing the friction on the thread. They also apply the doubling-frame for winding and spinning silk direct from the cocoons. The fourth improvement relates to reeling, and consists in winding the silk threads from the bobbins produced on the machines above referred to in skeins of 1,000 yards, or other suitable length; the size is ascertained by a balance with a graduated quadrant; these skeins are divided into portions of 100 yards. *Patent completed.*

550. W. STAUFEN. *A new or improved fibrous substitute for human and other hair, to be used for all the purposes for which human and other hair is now used, and also for the manufacture of textile fabrics.* Dated February 27, 1863.

The patentee claims—1, the sole use of the fibres of the leaves of the Elais Guincensis, and of the leaves of palms of the same family, as a substitute for human and other hair, in the manner and for the purposes described; 2, the sole use of the leaves of the Elais Guincensis and of the leaves of palms of the same family, for the manufacture therefrom of textile fabrics, in the manner and for the purposes described. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 11, 1863.

1449. W. Clark, 53, Chancery-lane, engineer. Improvements in obtaining and applying motive power, and in apparatus for the same. (A communication.)

Dated July 30, 1863.

1887. J. B. Howell, Sheffield, steel manufacturer. Improvements in ordnance, firearms, and projectiles.

Dated August 17, 1863.

2041. R. Baillie, Glasgow, engineer. Improvements in reefing or furling the sails of vessels, and in the apparatus to be employed therein.

Dated August 18, 1863.

2056. C. G. Wilson, Blackheath, civil engineer. Improvements in machinery for pressing cotton, and for crushing and pressing other substances, the said machinery being adaptable for locomotion on railways or on common roads.

Dated August 27, 1863.

2119. C. Richard, 10, Rue de la Fidelité, Paris, gentleman. A new or improved apparatus for lighting and cutting the ends of cigars.

Dated August 31, 1863.

2145. G. Attock, engineer, Stratford. Improvements in assistant bearing springs for locomotive engines, railway carriages, waggons, and trucks.

2148. G. Bebbington, Manchester, salesman, and J. R. Hampton, packer. Certain improvements in means to be employed for securing the ends of bands in packing "bale goods," and in machinery for manufacturing "rivets" to be employed for the purpose, and also in apparatus for forming apertures in the aforesaid bands or hoops.

Dated September 1, 1863.

2160. P. Joyot, jun., Paris, manufacturer. An improved fabric, and improvements in looms for manufacturing the same.

2161. J. H. Banks, Radnor-street, Hulme, Manchester, church furniture manufacturer. Improvements in the construction of benches or desks for schools, churches, and other similar purposes.

Dated September 2, 1863.

2167. R. Young, Glasgow, millwright and engineer. Improvements in separating and elevating apparatus for grain or granular matters.

2168. E. Collier, High-street, Leicester, milliner and crinoline manufacturer. Improvements in crinolines and crinoline fastenings.

2171. E. Alcan, King-street, merchant. A new method of, and apparatus for, feeding wool and other textile and filamentous substances into carding, combing, and other machines for treating such substances. (A communication.)

Dated September 3, 1863.

2173. C. Jackson, Birmingham, engineer and machinist. Improvements in bolts for fastening doors, windows, shutters, and for other like purposes.

2175. A. A. Beaumont, 2, Rue Sainte Appoline, Paris. A new or improved engine for raising liquids.

2181. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved apparatus for cleaning and decorticating grain and seeds. (A communication.)

Dated September 5, 1863.

2187. W. Lorberg, 4, Wyld's-rents, Bermondsey, analytical chemist. Improvements in the manufacture of gas and other substances from tan and similar materials.

2189. S. Mellbourn, Wallington Paper Mill, Carshalton, Surrey, paper maker. Improvements in the preparation of materials for the manufacture of paper, and in the construction of machinery employed for such purposes.

2191. T. Moody, Wincauton, Somerset, gentleman, and E. T. Moody, Chelsea Villas, West Brompton, civil engineer. Improvements in the generation and production of motive power to be applied generally, and in its special application to the propulsion of vessels.

2192. J. Rowell, Aberdeen, manufacturer. Improvements in the manufacture and construction of fences, part of which are also applicable to the manufacture and construction of gate-posts, and to poles and posts used for telegraph and signal purposes, and for stretching telegraph wires.

2193. T. Smith, Wolverhampton, merchant. An improved waggon break.

2195. C. H. Adames, Birmingham, manufacturer. Improvements in the manufacture of lids or covers for certain articles of hollow ware.

Dated September 7, 1863.

2197. F. Mills, Heywood, machine maker, T. Booth, mechanic, and T. Clegg, foreman. Improvements in machinery for preparing and spinning cotton and other fibrous substances.

2199. N. Singleton, Manchester, commission agent. Certain improvements in machinery or apparatus for cutting hay, straw, or other similar agricultural produce. (A communication.)

2201. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved apparatus for directing motion in right lines. (A communication.)

Dated September 8, 1863.

2203. L. Mond, Appleton-in-Widness, Lancashire, chemist. Improvements in obtaining sulphur and sulphurous acid from alkali waste.

2205. J. C. Lott, Clyro (near Hay), Radnor. Improved apparatus for turning over the leaves of music.

2208. T. H. Baker, Tunbridge, Kent, engineer, and G. Friend, engineer. Improvements in treating excrementitious and sewage matters, and in the means or apparatus employed therein.

2209. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in machines for working and preparing skins. (A communication.)

Dated September 9, 1863.

2213. W. H. Tucker, 6, Southampton-street, Strand, lock manufacturer. Improvements in the modes of propelling and steering vessels.

2217. W. Glydon, Birmingham, manufacturer. Improvements in apparatus and machinery for the manufacture of metallic tubes and hollow cylinders, part of which improvements may also be applied to the casting of other hollow bodies.

2219. W. E. Gedge, 11, Wellington-street, Strand. Improvements in paving roads or ways. (A communication.)

2221. J. Robinson, Batley, York, stone mason. Improvements in steam boiler and other furnaces.

2223. N. Thompson, 15, Abbey-gardens, St. John's Wood. Improvements in apparatus for stopping bottles, jars, and other vessels, which improvements are also applicable for stopping the muzzles of firearms.

2225. W. Hutchinson, Salford, engineer. Improvements in steam engines.

2227. J. Maggs, Bartlet-street, Bath, decorator. An improved construction of fountain pen.

Dated September 10, 1863.

2231. W. W. Greener, Birmingham, gun maker. Improvements in breech-loading firearms.

2232. H. and J. W. Wright, Freedom Mills, Morton, near Bingley, Yorkshire, paper manufacturers, and W. Clough, Keighley, engineer. Improvements in glazing and rolling press papers, pasteboard, and other paper requiring to be glazed or rolled, and in the means or apparatus employed therein.

2233. M. A. Muir, Glasgow, and J. McIlwham, machinists. Improvements in machinery or apparatus for winding yarns or thread.

2234. W. Clark, 53, Chancery-lane, engineer. Improvements in the purification and disinfection of hydro-carburets, and especially of oils produced by the distillation of coal schist and boghead. (A communication.)

2235. J. H. Whitehead, Royal George Mills, near Manchester, woollen manufacturer. Improvements in the manufacture of felted fabrics.

Dated September 11, 1863.

2236. J. Hartshorn, Nottingham, lace manufacturer, and W. Redgate, draughtsman. Improvements in the manufacture of lace, and in means or apparatus employed therein.

2237. W. Taylor, Lawton Iron Works, Shiffnal, Salop, ironmaster. Improvements in the manufacture of iron rods, and in machinery to be employed in the said manufacture.

2238. L. Desens, Paris, No. 18, Rue de l'Echiquier, gentleman. An improved bath or bathing machine adapted for deep water.

2239. T. J. Sloan, Paris, engineer. Certain improvements in braiding machines.

2240. J. Rhodes, Morley, near Leeds, machine maker. An improvement in piecing machines.

2242. J. Dobbie, St. Petersburgh, civil engineer. Improvements in the construction of railway and other carriages.

2243. J. D. Lee and J. Crabtree, Shipley, near Bradford, York, machine makers. Improvements in looms for weaving.

2244. H. Chrichley, Birmingham, manufacturer. Improvements in stove grates and kitchen ranges.

2245. M. Gerstenhofer, Freiberg, Saxony. An improved construction of furnace for roasting pyrites.

Dated September 12, 1863.

2246. J. Crellin, Lime-street, Liverpool, plumber and brass founder. Improvements in appara[illegible] [illegible]erning and stopping the flow or passage of liq[illegible]

2247. J. King, Glasgow, chemist. Improved means for assisting and regulating the process of fermentation.

2248. O. E. Wallis, Millman-street, Bedford-row, Holborn. Improvements in revolving firearms.

2249. E. N. Gregory, Camberwell, wire cloth manufacturer. An improved method of uniting belts and lengths of wire gauze and other metal cloth.

2250. W. Clark, 53, Chancery-lane, engineer. Improvements in revolving firearms. (A communication.)

2251. D. S. Sutherland, 34, Great George-street, Westminster, civil engineer. Improvements in blasting rocks and other materials.

2252. J. A. Whipple, Boston, United States. Improvements in apparatus for supporting photograph cameras.

Dated September 14, 1863.

2254. W. R. Hutton, Glasgow, manufacturing chemist. An improved lubricating compound.

2255. T. Bell, Wishaw, manager. Improvements in apparatus for distilling shale or other bituminous minerals.

2257. G. F. Millin, Oxford. Improved arrangements for facilitating the quick detachment of horses or draught animals from carriages or vehicles, and for the application of break-power with the view to prevent accidents.

2258. G. W. Billings, New York. An improved method of preparing the fibres of hemp, flax, and other vegetable materials, for manufacturing purposes.

2259. W. Gassage, Widnes, Lancashire, chemist. Improvements in drying or curing certain vegetable productions.

Dated September 15, 1863.

2260. C. Battock, Wandsworth, fusee and match maker. Improvements in cigar lighters and fusee matches, part of said improvements being applicable also to vestas and matches, wax tapers, and candles.

2261. G. Howell, Old Kent-road, stationer. Improvements in machinery for stamping or obliterating and printing, especially applicable to post-office purposes, parts of which improvements are applicable to machines in which cams are employed.

2262. W. Thompson, 5, Rue Neuve des Martyres, Paris. Improvements in electric telegraph apparatus.

2263. A. Barclay, Kilmarnock, engineer. Improvements in locomotives or other steam engines.

Dated September 16, 1863.

2267. J. Cox, George Mills, glue maker. An improvement in swings.

2268. J. Rahill, Minories, mariner. Improvements in liquid compasses.

2269. A. Watson, King-street, City, engineer. An improvement in hinges.

2270. J. Daunatt, Sunderland, plumber. Improvements in the construction of apparatus for cooling liquids.

2271. B. Latchford, Upper St. Martin's-lane, bit and spur maker. An improved spur.

2272. B. J. Webber, Newton Abbot, Devon. Improvements in threshing machines.

2273. R. Thompson, Manchester, silk manufacturer. An improved mixed fabric, and in the application thereof to covering umbrellas and parasols.

2274. E. Scott, Manchester, engineer, and J. Starkey, Salford, overlooker. Certain improvements in looms for weaving.

2275. R. Harrington, Birmingham, umbrella furniture manufacturer. Improvements in umbrellas and parasols, and in parts thereof.

2276. J. M. Tate, Bermondsey Wall, Bermondsey. An improved method of hanging the lower topsail yards of ships and other sailing vessels.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, September 29, 1863.

1220. B. Shillito and D. Moor. Generating heat and motive power.

1227. J. Papin, C. Lintz, and L. Lavacherie. Manufacture of boots and shoes.

1228. R., W., and T. Waddington. Combs for combing wool by machinery.

1229. B. Browne. Manufacture of elastic material. (A communication.)

1232. F. M. Burns. Preventing the fouling of the bottom and sides of ships and vessels.

1236. W. White. Manufacture of looped fabrics.

1237. T. C. Stretton. Dressing lace or other fabrics.

1240. E. Christmas. Carriages for common roads.

1243. A. Heather and J. Redfern. Steam-boilers.

1249. S. Rhodes. Twisting and doubling cotton, hemp, flax, and other like fibrous materials.

1261. H. Wren and J. Hopkinson. Lubricating bearings.

1271. J. Steart. Extracting the fibre from zostera marina and other aquatic vegetable productions.

1278. E. Sonstadt. Manufacture and purification of the metal magnesium.

1280. J. Goodman. Velocipedes.

1282. W. Snell. Butt hinges. (A communication.)

1284. T. A. Blakely. Ordnance.

1286. T. A. Blakely. Rifling guns and forming projectiles to correspond therewith.

1290. J. Higgins and T. C. Whitworth. Roving, spinning, and doubling cotton and other fibrous materials.

1292. J. Sturgeon. Steam hammers.

1295. W. Cormack. Distillation of coal tar, tar oil, resin, resin oils, all hydro-carbons, petroleum, or other mineral or vegetable oils and spirits derived therefrom.

1296. S. E. Rosser and J. G. Jennings. Chimneys, fire-places, stoves, and flues for warming and ventilating apartments.

1297. J. S. Bickford and G. Smith. Firing explosive compounds.

1303. R. A. Brooman. Safety garments. (A communication.)

1305. G. Smith. Burning hydro-carbon oils. (A communication.)

1306. J. Hesford. Machinery and apparatus for stretching and drying fibrous materials.

1307. W. Muir. Machinery for cutting sugar.

1315. J. Hilliar. Construction of frames, sashes, shutters, blinds, and ventilators for windows or other openings.

1318. M. J. Roberts. Preparing, spinning, twisting, and doubling wool, cotton, and other fibrous substances.

1320. W. Clark. Ruling paper and other materials. (A communication.)

1326. F. W. K. and J. Kitson. Tyres for railway wheels.

1328. A. P. Hernandez and P. B. Crespy. Manufacture of soap.

1338. G. Gore. Gas-burners and gas-furnaces.

1340. H. Cartwright. Steering vessels.

1341. C. F. Baxter. Elastic stopper.

1349. A. Abadie. Railway breaks.

1352. G. H. Pierce. Heating buildings.

1379. E. J. Jarry. Machinery to be worked by steam or other power for clearing and ploughing land.

1384. J. Travis. Preventing the incrustation of earthy matter in steam boilers.

1405. W. Clark. Distillation and separation of hydro-carburets and their derivatives. (A communication.)

1502. F. S. Williams. Shaping plastic materials. (A communication.)

1503. W. Manwaring. Harvesting machines.

2056. C. G. Wilson. Pressing cotton.

2116. F. Pragst. Steam engines.

2148. G. Bebbington and J. R. Hampson. Securing the ends of bands in packing "bale goods," and in machinery for manufacturing "rivets."

2217. W. Glydon. Manufacture of metallic tubes and hollow cylinders.

2223. N. Thompson. Stopping bottles, jars, and other vessels.

2239. T. J. Sloan. Braiding machines.

2273. R. Thomson. A mixed fabric and the application thereof to covering umbrellas and parasols.

2320. W. Elsdon. Rail and road carriages.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated September 21, 1863.

2320. W. Elsdon, Sandridge, Bourke, Victoria, engineer. The construction of rail and road carriages and improved wheel tyres, and an improvement in railway crossings, adapting them to such carriages.

LIST OF SEALED PATENTS.

Sealed September 25, 1863.

326. H. Dircks and J. H. Pepper.
803. R. A. Brooman.
813. W. Symons.
815. J. Dale and G. Bischoff.

MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 9, 1863.

TWIN-SCREW STEAMERS.

FROM time to time reports have appeared in our pages of the performance of a few vessels built on the twin-screw principle by Messrs. Dudgeon, of Blackwall. The results obtained have been so satisfactory, that the subject is rendered worthy of deep consideration. To whom we are indebted for the first idea of this principle, it is not easy to determine. Captain Carpenter, of the Royal Navy, was perhaps the first to reduce it to a practical shape. This gentleman obtained a patent for his invention; but as he employed but one engine, he was unable to avail himself of the most important feature of the whole principle—that of using each screw separately, in order to turn the vessel. Mr. Richard Roberts, many years ago, proposed to overcome this difficulty by the use of independent engines; and it is to their use that the success of the "Flora," "Kate," "Ceres," &c., is mainly due. By running one screw ahead and the other astern, these ships are turned with ease on their centres as on a pivot, without changing their places more than a few feet in still water; the rudder having little or nothing to say to this action, as the ship has no way.

The application of two screws to the propulsion of sea-going ships has met with a vast deal of opposition; many persons considering it impossible that vessels so fitted could prove good sea-boats. This idea still obtains, to some extent; all sorts of objections being used against the use of double keels, &c. We must recollect, however, that not on this side of the Atlantic alone is the principle adopted with success; the Americans possessing many vessels both in the navy and mercantile marine so fitted, which have given the greatest satisfaction. Facts, such as these, are worth much more than theoretical reasoning, grounded on assumptions, the fallacy of which is demonstrated by actual practice.

In another of our pages will be found the report of the recent trial trip of the twin-screw steamer "Ceres." This vessel is built without a double keel, a three-bladed screw working under each quarter. The screw shafts are supported outward by means of V brackets just in front of the blades. The engines are horizontal direct-acting; the cylinders, which are cast in pairs, being placed nearly over the keel, with the condensers, which are of the ordinary injection variety, between their ends and the ship's side. The air-pump buckets are worked by a prolongation of the main piston rod through the cylinder bottoms. The starboard engine is placed forward; the shaft of the screw on that side running between the bottoms of the larboard cylinders and their condensers. The framing of the engines is very neat and compact; and the engine room one of the most convenient we have ever seen. A small fan is fitted inside the stoke-hole bulkhead, in order to aid the draft in the furnaces, which it does effectually; the boilers making an abundance of steam with very moderate firing. There can be no doubt that the subdivision of a certain amount of power among a number of cylinders affords peculiar facilities for the construction of engines intended for screw propulsion; and not the least advantage attending the use of two screws is found in the fact, that the position of the screw shaft permits the employment of a connecting rod of fair length attached directly to the piston rod. The use of the V brackets, however, cannot be regarded as commendable. Not only do they offer very great resistance to the motion of the hull through the water, but the peculiar position of the screws, with their inner blades only removed a few inches from the keel and dead wood, at each side of which they work, injures their action very materially, causing a good deal of vibration, and preventing a clear run of water to the blades. In order to overcome these objections, Commander Symonds, R.N., in a Paper on the Construction of Screw Steamers, read at the Royal United Service Institution in March, 1862, advocates the use of two hollow keelsons, each containing a screw shaft. The dead wood in the centre being done away with, a half-rudder is fitted to each keelson under the screw shaft—a mode of construction which would, we imagine, effectually overcome most of the objections at present raised against the use of double-screws.

We begin, at last, to understand that the ship which can steam at the greatest speed on the lightest draught of water, and manœuvre with the most ease, must be the best for all the purposes of warfare. Were the use of armour-plating and heavy guns confined to the British Navy, the question of speed would be of secondary importance: our ships being comparatively impregnable could set an enemy at defiance. Other nations, however, have resorted to the same principles of construction as those we have adopted. Guns and armour-plates are not peculiar to our ships; and modern navies are, after all, very much in the same position, as to their relative powers of attack and defence, as that which they held half a century ago. If the strength of modern war-ships has been immensely increased within the last few years, so have been their powers of destruction; and a sea-fight would be now, more than ever, a question of naval tactics and rapid evolutions. Under sail alone, none of our large frigates can be depended on either to stay or wear; some of them requiring three miles for the former and seven for the latter. Under steam they perform better; still the operation of turning is tedious in the extreme, and cannot be accomplished in crowded or narrow waters without considerable danger. The use of two screws would enable the largest ship in the Navy to turn on her own centre as on a pivot, placing her really under the control of her officers. It might, indeed, be practicable to construct a very efficient fighting ship on this principle, armoured at the bow alone with plates, thick enough to set a shot at defiance, and carrying a couple of 150 lb. Parrot guns there. Such a ship would be a match for almost any single adversary, from the ease with which, turning as on a pivot, she would always present her armed head to the foe. If very large guns are ever to come into use, it will only be by mounting them on the ship as a gun-stock and training them by changing her position.

The principle on which the success of Mr. Dudgeon's craft has depended, is neither new nor untried. In 1845, Ericsson built a small double-screw steamer for the Marine Insurance Companies of Boston, U.S. This vessel was used for many years in and about that harbour, for the purpose of rescuing ships which had got into dangerous positions. She could navigate the most intricate passages with the greatest ease by means of her screws, turning in her own length in a remarkably short space of time. The Insurance Companies calculated that she saved them many millions of dollars during her career. On one occasion, she rescued one of the Cunard steamers from a very dangerous dilemma, and brought her safely into Boston harbour. She remained in that service until the commencement of the war, when she was purchased by the Federal Government and fitted as a gun-boat, in which capacity she did good service until she was wrecked last winter. The "Nangatuck," an American gunboat, repeatedly turned end for end, during public experiments, in 1 min. 15 sec. She was fitted with twin-screws, and had a single 100-pounder Parrot gun on a fixed carriage, there being no possibility of moving the gun laterally, except by turning the ship. The celebrated Stephens' battery, with fixed turrets, is also fitted with two screws, worked by independent engines. The system is, in fact, rapidly extending in America.

The question, therefore, for our Government is no longer, whether it will or will not take the initiative in the introduction of a new principle, but whether it will follow the example set by other nations. Thousands of pounds are wasted annually on costly experiments which frequently result in nothing. But the twin-screw principle is objected to in very nearly the same words as those employed in the reply to Ericsson, when he urged the adoption of the screw-propeller on the Lords of the Admiralty—namely, "that the paddle-wheel answered their purpose sufficiently well." The single screw also answers their purpose, we are informed; and the only experiment which the Government will make, is the construction of a double-screw boat of 30 tons burden! We really imagine that, with the example of a private firm already before them, the Lords of the Admiralty might have adventured a few thousand pounds on a ship large enough to go to sea and face a gale of wind, instead of a few hundreds in a miserable little craft, more suitable for a pleasure-yacht, than for the first official embodiment of an important principle. Those in authority maintain that the screw must be regarded more in the light of an auxiliary power, to be rarely employed, than in that of a permanent means of propulsion—in other words, the Lords of the Admiralty state that the work of the fleet must be done by sails, and that therefore, from some ideal difficulties connected with the elevation of double-screws, they are unsuitable for use in the Navy. The absurdity of this conclusion has rarely been surpassed. The screws can be raised, on Captain Symonds' principle, with the greatest ease; and even if they could not, they could either be disconnected, feathered, or driven by donkey-engines. With her screws up, a double-keel vessel really becomes a good sailing ship, which the single-screw ship never can, in consequence of the injurious effects of the opening in her dead wood, and the resistance caused to her progress by the after stern-post dragging through the water. As to the expediency of sacrificing much that is valuable, in order to retain the power of converting a good steam-ship into a bad sailing one, we do not wish just now to express an opinion. By a recent dictum we learn that sails could probably be dispensed with, provided the ship could carry thirty days' coal—an object which, we imagine, may yet be secured without very great difficulty.

V. P.

GREEK FIRE AND TORPEDOES.

As yet, engineers have had all their own way in the recent extension of the powers of destruction; chemists have practically done but little beyond the invention and improvement of gunpowder. The latent powers of destruction in many substances known to modern

chemists are, however, immense, and it is not improbable that the chemical knowledge of the 19th century may some day bring forth a similar revolution in warfare to that effected by the chance discovery of gunpowder by the alchemists of the Middle Ages. To the development of chemical destructive power, directed by the modern resources of engineering, we may, perhaps, look to the realization of the hope that war may be rendered a physical impossibility. We say *perhaps*, as the realization of this hope—the specious balm self-administered by all the conscience-stricken inventors of implements of warfare—has always appeared to us more than doubtful. Given two rival armies or navies, each provided with an infallible wholesale and instantaneous means of destruction. Would not each party hope and trust that it may be beforehand in the application of the wholesale death potion?

However this may be, we already see at Charleston in the Federal bombs charged with Greek Fire, and in the infernal machines used by the Confederates—two distinct applications of a warlike union of chemistry and engineering. The exact composition of the Greek Fire with which the Federal shells are charged, is naturally a secret; the prevalent opinion seems to be that it principally consists of either naphtha or spirits of wine. That this is the case, we have lately obtained some corroborative evidence. In searching through an old book—the "Natural Magick," of Baptista de Porta—published in Italy towards the middle of the 16th century, we alighted on the following recipe and short history of "Greek Fire," which we copy *verbatim* as follows:—

By the subtilty of the Greeks there was invented a fire, called Greek Fire. To overcome the ship, presently, they boyl'd Willow-coals, Salt, Spirit of Wine, Brimstone, Pitch, with the Yarn of the soft Wool of Ethiopia, and Camphire; which, it is wonderful to speak, will burn alone in winter, consuming all matter. Callimachus, the architect, flying from Heliopolis, taught the Romans that thing first, and many of their Emperors did use that against their Enemies afterwards. Leo, the Emperor, burnt with this kind of Fire those of the East, that sail'd against Constantinople with 1,800 Camels. The same Emperor, shortly after, burnt with the same Fire 4,000 ships of the Enemy, and 350 in like manner. Prometheus found out that fire would keep a year in the Cane Ferula: wherefore Martial speaks of them thus:—

Canes, that the Master's love, but Boys do hate,
Are by Prometheus's gift held at a great rate.

It will be seen that, what druggists call the "vehicle," by which the ancient Greek Fire was administered, consisted simply in a "kind of tow or yarn." This would, no doubt, answer well enough against wooden ships; the Americans, however, have naturally filled their bomb-shells with this destructive composition.

In the following passages, it will be seen that the Mediæval Italian *savant* has also anticipated the Confederates in the construction of naval infernal machines. Indeed, in many situations, Baptista de Porta's infernal machines would probably be more efficacious than those of General Beauregard—especially in shallow situations. A torpedo of this kind, fired by means of the galvanic wire, would probably effect great havoc in a fleet.

Baptista de Porta's plan will be found described on the 298th page of his book, under the title of "*How in plain ground and under waters mines may be presently digged:*"—

You shall make your Mines where the enemies' Galleys or Ships come to ride; you shall upon a plain place fit many beams, or pieces of timber, fastened cross-wise, and thrust through, or like nets; according to the quantity in the divisions, you shall make fit circles of wood, and fasten them, and fill them with gunpowder; the beams must be made ..., and be filled with match and powder, that you may set fire to the round circles; with great diligence and cunning, smear over the circles and the beams with pitch, and cover them well in it, that the water may not enter, and the powder take wet (for so your labour will be lost), and you must leave a place to put fire in; then sink your engine with weights to the bottom of the water, and cover it with stones, mud, and weeds, a little before the evening come. Let a Scout keep watch, that when their Ships or Galleys ride over the place, that the snare is laid; for fire being put to it, the sea will part, and be cast up into the air, and drown'd the ships, or will tear them in a thousand pieces, that there is nothing more wonderful to be seen or done. I have tried this in waters and ponds, and it performed more than I imagined it would.

MILLS AND MILLWORK.*

A century of mechanical engineering has not only introduced novelties in manufacturing processes, and the machines by which they are accomplished, but in our mechanists and that literature peculiarly their own. It does not need a very extended retrospect to recall the days when everything connected with prime movers, wheel-work, or mechanical appliances, dwelt in the hands of a class styled "millwrights," men as different in abilities, skill, and social habits, from any we now meet with, as it is possible to conceive. Illiterate and conceited, drunken and unmannerly, their presence was tolerated only because nothing better was to be had. Few and far between were the exceptional cases, wherein the faculty of "millwrighting" was coupled with that accurate knowledge of first principles, and a correct perception of their bearing on every point presenting a difficulty, which elevates the mechanic into the engineer. A few lights gleam through the darkness only to make the darkness itself still blacker; and it can scarcely be maintained that these men, as a class, have become merged in something greater and better. The modern mechanical engineer is almost a creation, scarcely a growth; and if this be true of the men, how much more so is it of their books. Fifty years ago a young man, studying what was scarce a trade, yet not yet arrived at the dignity of a profession, had no means of acquiring knowledge but personal observation. Within his own district the same arrangements of gearing, style of building, and constructive principles were repeated over and over, with a stereotyped uniformity, which gave opportunity for the acquirement of not one single novel idea; and travel alone, by bringing the youth into different scenes, and in contact with other men, could convert the servile imitator, into one, capable of originating new ideas, and developing them to a successful result. The knowledge to be derived from books was trifling. Not only were they expensive and rare, but a misty style of composition obscured the authors' meaning, and detracted materially from the usefulness of a class of literature, which was otherwise not without a certain value. Theoretical knowledge can never be disseminated without books; and without theory, it is difficult, indeed, to secure correct practice. In our day, we have little to complain of on this score; and the youth of this half of the 19th century might possibly become a very fair engineer, capable of designing, if not constructing, any machinery however complicated, without any workshop practice. Scarcely a subject coming within the range of the arts is left untouched. Able and exhaustive treatises, popular essays, newspaper articles, have brought mechanical science from the workshop to the fireside and the lecture-room; and, to books in vast degree, must be attributed the perfection of our steamboats, our railways, and our factories. Much of the time heretofore spent in manual labour, is now more usefully employed in study. Some will always have to design, while others find their mission in executing the works appointed them. Thought begets thought; and the progress of science is so rapid, that the field for engineering literature daily expands; and those books which comprise most practical information, well digested and arranged within the smallest compass, are certain to be regarded as most valuable. As a sample of such a book, it is perhaps difficult to select one better adapted to its end than that now before us. "In the first part of this book," says Mr. Fairbairn, in his preface to the present volume, "I endeavoured to give a succinct account of nearly fifty years' experience in the profession of a mill architect, millwright, and mechanical engineer. My professional career commenced just at a time when the manufacturing industry of the country was recovering from the effects of a long and disastrous war; and I was enabled from this circumstance to grow up with, and follow out consecutively, nearly the whole of the discoveries, improvements, and changes, that have since taken place in mechanical science." Mr. Fairbairn's name stands so high, that such an explanation of the causes, which gave him a peculiar fitness for writing a book on millwork, is hardly necessary. The reputation he has already earned as an author, is security that any work emanating from his pen will be valuable.

The first volume of "Mills and Millwork" was published in 1861. Commencing with a chapter on the Early History of Mills, the author treats successively of the principles of mechanism, of the accumulation, outflow, and discharge of water, the construction of water-wheels, turbines, &c., and concludes with a treatise on the steam-engine and boilers, and a chapter on windmills. The second volume, only published a few weeks since, is fully equal to anything Mr. Fairbairn has ever written. The first part is devoted to the consideration of machinery of transmission. The article on the teeth of wheels in this section is exhaustive and interesting, giving not only the rules for their correct formation, but the reasons for them, in a form which leaves little to be desired. Mr. Fairbairn very properly dwells on the importance of proper curves to the correct working of any train of gearing, pointing out the ease with which they may be secured by the use of the odontograph, a little instrument we could wish to see in more extended use than it is. The section is illustrated with a useful plate of examples of teeth, mostly drawn to full-size scale, on the different systems met with in the best practice. The second chapter, on the strength and proportion of shafts, is extremely able—we fear too much so—the author treating his subject in a style which would have been far too theoretical, were it not redeemed by practical tables calculated to meet every ordinary case. This section concludes with a chapter on engaging and disengaging gear, which scarcely leaves a single form of such apparatus undescribed.

In the fifth section which forms the second part of the volume before us, Mr. Fairbairn touches lightly on an important subject, too much neglected—Mill Architecture. We are rapidly drifting into a state of total disregard for the ornamental in such buildings as are intended to contain machinery; and our author might have extended this chapter with considerable advantage. It really requires no additional outlay worth naming to render a building—pro-

* "Treatise on Mills and Millwork." By William Fairbairn, Esq., C.E., LL.D., F.R.S., F.G.S. London: Longman and Co. 1863.

bably the most prominent feature in the landscape—pleasing to the eye, as well as adapted to the object in view. Mr. Fairbairn is an engineer, however, not an architect; so we hasten with him to the chapter on Corn-mills. The two which the author has selected as examples, are one of three pairs of stones erected at Constantinople for the Seraskier Halel Pasha in 1842, and the other of thirty pairs of stones, for a Russian Company at Taganrog, on the borders of the Black Sea. The first was built under the conditions that the building should be entirely of iron, that it might not be burnt to the ground by the fires which so frequently occur in the Turkish capital. The other was intended for the purpose of grinding the large supplies of wheat which are grown on the Steppes of Southern Russia for the European markets, and also for the supply of bread and biscuits to the Russian Navy. The descriptions of these mills are very copious, and accompanied by tables of the gearing and speeds of every shaft and wheel, from that of the prime mover to the sack tackle pulley—a feature as novel as it is valuable. Mr. Fairbairn pronounces strongly in favour of the bevel-wheel system—a sentiment with which most engineers will agree, as the disadvantages of spur-wheel hursts are very well understood. It is very remarkable that he should not once allude to the system of blowing air through the stones to keep the flour cool, the use of a stive-room, or, indeed, several details which are considered matters of necessity in a first-rate flour-mill of the present day. Nevertheless, the chapter cannot fail to prove useful to those interested, embracing as it does practical examples of machinery which has proved extremely successful.

During the Russian war, Messrs. Fairbairn and Sons were employed to fit up two screw steamers, the "Bruiser" and the "Abundance" as floating corn-mills, which they accomplished with perfect success in less than three months. Our author devotes a little space to a description of these mills, which were, perhaps, the first of the kind. The machinery was all driven from the propeller shaft, and the whole of the process performed without manual labour The wheat was stored in the fore hold; the four pairs of stones being arranged in a line directly over the screw shaft abaft the engines, and driven from it by bevel gearing. Ten sacks of flour per hour were frequently ground while the ships ran at the rate of 7¼ knots in the same time—a rather remarkable feat.

Mr. Fairbairn does not confine his observations to corn-mills. The latter half of the volume before us treating consecutively, at some length, of cotton, woollen, flax, oil, paper, powder, and iron mills; the architecture, fittings, and machinery of the two first being dwelt on with a care, which renders these chapters not less interesting than useful. In pursuance of the system generally adopted through the work, examples of mills in successful operation are selected as illustrations of correct principles of construction: plans and sections being supplied of the large factory built by Messrs Fairbairn for the Oriental Cotton Spinning and Weaving Company, near Bombay, and the Izmet Woollen-mills, erected by the same firm, for the Sultan, near the Gulf of Ancient Nicomedia. Flax-mills are illustrated by a mill erected at Narva, in Russia; while the new machinery at Waltham Abbey, serves the same purpose for the chapter on Gunpowder-mills. The entire work forms a most valuable book of reference. The engineer, even if inexperienced in the construction of any particular class of machinery, need never be at a loss for the correct solution of a minute question of detail. The tables interspersed through the book, give the speeds of all the machines treated of, from the smallest to the largest; while general information is put before the reader, in a pleasing and accessible form. We can cordially recommend the book to the mechanical engineer as one of the best of its kind. V. P.

HEAT.*

It is impossible to conceive of anything more intimately connected with, not only our well-being, but our very existence, than that principle of nature termed Heat. Mysterious in its attributes, strange in its powers, and remarkable in their development, heat has, for centuries, baffled the wisdom of the greatest philosophers. Amidst the host of treatises which have been written on the subject, the one before us deserves to take a place as one of the most remarkable, if not exact, and complete, which has yet appeared. Starting on the assumption, which he takes some pains to prove correct, that all previous hypotheses are incorrect and unsatisfactory, the author places yet another before us, in very remarkable language. Without asserting for a moment that his theory is perfect, his reasoning leads us to believe that it is, on many points, more satisfactoy than any which has gone before. Faraday was one of the first to enunciate the idea that force can have existence without any connection with matter. This view Mr. Colburn embraces and applies to heat. Successively reviewing and abandoning the material, motory, and molecular vortical theories, he considers heat as a pure abstract force, to some extent analogous to gravity. Most of the conclusions which he draws from these premises are, doubtless, correct. There is not a theory of heat in existence which is not open to objection in some respects. Perfect in some things, falling short in others, each seems to want what another can alone supply. The present is not an exception to the rule; still we welcome the book, because it throws light on many obscure things, and the author's propositions are, for the most part, very carefully reasoned out. The language is, perhaps, more suitable to men of science or philosophers than to engineers as a class. Yet many who are not very deeply versed in the mysteries of natural philosophy may read this little book with advantage; while to those who are, we recommend it as containing much food for careful thought.

* "An Inquiry into the Nature of Heat." By ZERAH COLBURN. London: Spon. 1863.

THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

The October meeting of this society took place on the night of the 3rd inst., at 35, St. Swithin's-lane, City. Mr. Joseph Newton, of the Royal Mint, occupied the chair; and the proceedings were commenced, as usual, by the reading and confirmation of the minutes of the preceding meeting. Afterwards the Chairman read a communication from M. Achard, C.E., in reference to sundry queries which had been put, but not answered, when, a month before, Mr. Gettliffe communicated his Paper on "Boiler Explosions and Railway Accidents." It will be remembered that M. Achard's apparatus, then described, was intended for the maintenance of a constantly level feed in steam boilers; and the first of the queries ran as follows:—"If the float, refusing to act, causes the index to remain at zero, while the water falls in the boiler, how can the alarum bell, in consequence of the non-interruption of the electric current, be made to give the required signal?" The answer to this objection was, that in M. Achard's arrangement a stone float was immersed in the water with a counterpoise on an exterior shaft. The articulation consisted in the friction of a steel roller on a plane of polished cast iron, instead of the old stuffing-box system, which was in many respects imperfect and liable to derangement. The resistance of the rolling friction was insignificant as compared with the gravitation of the stone float, and with that of the exterior counterpoise weight. The float known as "Bourdon's" also neutralized the objection raised; for it was scarcely possible for it to refuse to work freely, and it indicated alterations in the water level to the minute difference of 1-24th of an inch.

In reply to the second question raised—"Would it not be possible to cause the conducting wire to pass through the boiler, and communicate directly with the float?" M. Achard stated that the plan would be quite practicable. He had carried it out with success at Lyons, in the manufactory of Messrs. Coignet. In that case, the conducting wire was subjected to continual friction, which prevented oxidation, and the current circulated quite as freely as with Bourdon's float. The disadvantage of the arrangement, however, was that it precluded the application of an indicator on the face of the boiler, which was legally imperative in France. The Bourdon float, therefore, superseded it, and it met every requirement.

The third of the series of queries was—"Which would be the best and most economical means of keeping the automatic regulator in operation during the temporary stoppage of the machinery and the absence of the workmen?" It was replied that, in order to secure this desideratum, which had not escaped the early consideration of the inventor of the regulator, he had at first added to it a direct electrical bell, which rang the alarm by means of the circulation of the electrical current, so that when the current no longer circulated for the regulator, it circulated for the direct electrical alarum—this latter operating notwithstanding the suspended action of the machinery. Of course the alarum in such case might be fixed in any convenient place—the office of the manager of the factory, for example. It had been found that this was but an extra precaution, which it was not absolutely essential to take, for the water in the boiler never descended, during such temporary suspension, more than an eighth or a quarter of an inch. A little reflection, indeed, would show that when an engine was stopped *pro tem.*, the index of the regulator pointing to zero, the water could not, owing to the non-consumption of steam, decrease more in height than had been stated.

The querists having acknowledged themselves satisfied with the explanations of M. Achard, the Chairman next proceeded to revert to the loss which the Association had sustained by the decease of one of its honorary members, Mr. William Buckle, of the Mint. In feeling terms, the last hours of his late colleague were described by Mr. Newton, who read also a brief sketch of the deceased gentleman's life and career as an engineer. Mr. Buckle was born, he said, at Alnwick, Northumberland, July 29, 1794, and was educated at Hull, in Yorkshire. Soon after he had left school his parents removed to London, and he was apprenticed to Messrs. Woolf and Edwards, millwrights and engineers, of Holland-street, Blackfriars-road. His conduct during his apprenticeship was exemplary, and his evenings were spent, for the most part, at a drawing school in Finsbury. In the year 1817 Mr. Buckle went, at the instance of Messrs Humphrys, to Memel, to establish steamboats on the rivers and lakes of Prussia, under the patronage of the Prince of H..r..lenburg. Whilst in that country he was fortunate enough to save from drowning a young lady of the Prince's family, and to receive for his valorous conduct a gold medal. Mr. Buckle remained at Memel for four years, and returning at the end of that time to England, was entrusted with the charge of the engines of the first steam mail packet between England and Ireland *via* Holyhead and Dublin, under the then Postmaster-General, Sir Francis Freeling. In 1820 he superintended, so far as his special department was concerned, the voyage of George IV. to Ireland, in a steamship then known as the "Lightning." The name of this vessel was

ubsequently exchanged for that of the "Royal Sovereign," and afterwards, *mutatis mutandis*, for that of the "Monkey," under which last designation she now does duty in the Thames as a tug-boat! Mr. Buckle, after having safely conducted "the first gentleman in Europe" (save the mark) back to England, was engaged by Messrs. Boulton and Watt as manager of their engine works at Soho, near Birmingham. In this capacity he remained for the space of 33 years, enjoying during that lengthened period the friendship of his employers, as well as of the numerous *savants* who visited in succession that shrine of science, "Old Soho." In 1851, Mr. Buckle, having followed to the grave the original partners of the eminent firm in question, transferred his services to the Royal Mint. At this establishment important changes were at that time made. A Royal Commission had recommended the removal from their posts of the Company of Moneyers; and the Government acting upon the recommendation, pensioned off the members of that company; the place became, therefore, exclusively a national establishment, and Mr. Buckle was appointed one of its principal executive officers. That post he occupied up to the day of his death, although failing health had, for many months previously to that event, prevented his active performance of duty. During those months the reader of this brief sketch had the honour of officiating at the Mint for his disabled friend and colleague; and perhaps no one had been able more fully to appreciate the kindly disposition, the amiable temper, and the practical talent of the deceased gentleman than himself. It would be possible to enumerate many [remarkable mechanical works in which Mr. Buckle was engaged during his managerial career at Soho; but as it was likely that these would be referred to at length in a memoir which was being prepared for publication, it was not necessary to particularize them.

Much emotion was exhibited by Mr. Newton in the reading of the above, and the general feeling pervading the members at the time was evidently one of extreme sorrow. Finally, it was proposed by Mr. Oubridge, seconded by Mr. Jones, and unanimously carried, "That the Secretary should be directed to convey in writing to Mrs. Buckle and her two children the condolence of the Association of Foremen Engineers under pressure of their heavy bereavement."

On the conclusion of this painful episode in the proceedings of the evening, Mr. T. Miller read a very elaborate Paper on an "Entirely new Method of Coating Telegraph Wires." This was illustrated by a series of admirably-finished diagrams, and was replete with interest. At a future period we may give an extended report of this communication; but lack of space at present compels us to summarize its principal features. Mr. Miller proposes to cut sheets of india rubber from blocks in such a manner that the knife-cuts or corrugations shall run in a longitudinal direction, or nearly so, with the sheet. He has also constructed an apparatus for preparing the strips for the covering machines, as well as covering machines themselves. In the latter, the principal points of improvement consist in the employment of sets of hollow spindles placed one within the other and to be driven at different speeds. A third arrangement is the drawing or stretching apparatus mounted on spindles and to act independently of the friction of the bobbin on its spindle. Another main characteristic of the series of ingenious contrivances in question is, the application of a current of electricity, by the action of which the working of the covering machine will be self-actingly stopped when the insulation is imperfect.

The Chairman remarked, at the conclusion of Mr. Miller's Paper, that he had rarely heard a more complete description of a variety of ingenious combinations of machinery, for the effecting of an important object, than that which he had just listened to. In every way Mr. Miller deserved their thanks—in the first place, for the demonstration of his skill as a mechanic and draughtsman; and in the next, for the clear and intelligible way in which he had put the whole subject before the meeting.

A vote of thanks having then been put and carried, *nem. dis.*, the members of the society separated.

SCIENTIFIC GHOSTS.

By H. Dircks.*

Sir David Brewster has judiciously remarked that, "although it is not probable that we shall ever be able to understand the actual manner in which a person of sound mind beholds spectral apparitions in the broad light of day, yet we may arrive at such a degree of knowledge on the subject as to satisfy rational curiosity and to strip the phenomena of every attribute of the marvellous." I cannot say of the work in question that the many ingenious illustrations given as the result of natural phenomena or scientific combinations lead to the anticipated result, for in every instance adduced the aerial or spectral figures are but isolated visions, or, when produced artificially, are of very limited application.

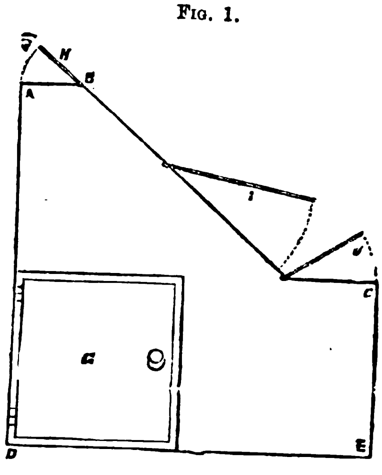
The peculiar features of the optical arrangement I introduce may be thus stated:—Two or more figures, for example, appear on a stage, and the spectators view them as two living actors, in all respects the one as well defined and obviously round and life-like as the other, yet one shall be a material and the other only a visionary actor, results obtained in a manner by no means in accordance with the before-named views expressed by Sir David Brewster. We may suppose a theatre or apartment, arranged as customary when required for dioramic exhibitions, a stage being provided and the spectators placed in a distant, darkened, and elevated portion of the building. The spectators, thus situated, may, for example, see on an illuminated stage two or more figures, but without being aware that one or more of them bears a visionary character. The peculiarity of this mode of exhibiting spectral appearances, it will be understood, consists in thus associating a living or solid figure with a merely visionary one, and yet the illusion to be so well sustained that the spectator distinguishes no visible difference between the several actors when properly managed until the circumstances of the dramatic scene require the visionary figure to fade away or pass through the furniture and walls of the apartment, or play any similar spectral part.

It is more than twenty years since I first invented a plane mirror of unsilvered glass, but, finding no practical utility in the contrivance, it was laid aside. It happened, however, that within the last two years I accidentally observed a solid body in a peculiar situation, by which it was apparently rendered transparent. It was, in short, an effect illustrated by my plane unsilvered glass mirror in its principle. I immediately saw that by means of this combination the singular appearance could be produced, of getting behind a mirror and communicating with its shadows. Here, then, a means was at once at hand for producing the best possible illustrations of all descriptions of spectral phenomena. For this purpose I arranged an oblong chamber into two equal portions, making the separation between the two by means of one vertical screen of thin glass, having a perfectly true surface. We may suppose each chamber to measure 12 feet square and 12 feet high. Now, let one of these be the stage in which the acting is to take place, its floor and three of its walls are solid, and the fourth or front of it is one entire glass screen: the ceiling must be made to open at different parts to let in light, and have suitable blinds to regulate the light and shade in which the actors perform. The chamber opposite, or facing the actors, is in reality a second stage for carrying out the spectral performances, and is differently constructed; the two sides may be large folding or sliding doors, or may be left quite open, or one side closed and the other open, but the ceiling must cover only that half of the top away from the glass screen or partition, thus leaving an open space in the ceiling of 6 ft. by 12 ft. Through this space so left in the ceiling the spectators obtain a full view of the stage, their seats being above the half-ceiling described, and thrown rather backwards than forwards; the line of vision thus being at an angle of about 45 degrees with respect to the vertical glass screen or plane unsilvered crystal mirror. It will now be obvious that the actor on the stage beneath the seats of the spectators can only be seen by reflection, and the trained actor in the opposite stage, knowing the precise situations of the reflection as seen by the spectators, performs accordingly, so that, when really seeming to stand confronting the vision, the actor whose reflection is thus seen as a vision, is as far from the screen on one side as his reflection is cast in the other.

Some striking effects may be produced illustrative of the illusive properties of optical apparatus constructed on the principle described. Thus, a figure placed before a white screen is so strongly reflected that the spectator cannot divest his mind of there being the substance and not the shadow, which he observes, particularly as he contrasts them with an adjacent solid figure. By placing two figures of corresponding form equidistant, one on each side of the glass mirror or screen, they appear as one, until one is moved; and if they differ in colour, as one blue and one white, the effect seems more remarkable. If a cabinet, box, or the like is placed one on each side of the mirror until the image of one exactly corresponds with the material figure of the other, then the spectator may see the visionary figure open a drawer or door and remove and replace anything therein, and afterwards the solid figure repeat the same acts. If the reflection of an actor is thrown on a transparent screen it is invisible, but by gradually decreasing the light the spectral appearance will be as gradually developed, until apparently it becomes a firm, solid figure in all its proper costume, and acting in perfect conformity to its designed character.

The arrangement of the apparatus is represented by the annexed engravings. Fig. 1 is a side elevation, fig. 2 a vertical section, and fig. 3 a plan. A B C D E is a box closed on all

Fig. 1.



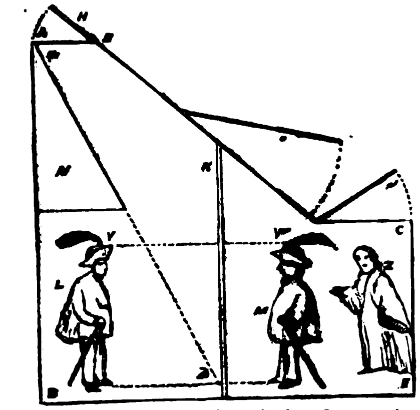
sides, but provided on one side with the door F, and on the other with the door G, hinged to the back, A D; and on the top of the box are the flapped openings H, I, J. The interior of the box is divided centrally by the partition K K, made of a good, clear, and even-surfaced piece of thin patent plate glass, kept in its place within two side grooves. The box is thereby divided into two separate chambers or compartments, L, M, the latter, M, having a ceiling or screen, N, to exclude any object therein from the direct view of the spectator, as shown by the line *a b*.

If two figures be now introduced, one Y, the other Z, and the eye of the spectator be fixed at A, he will observe two images, one the real figure Z,

* Read before the British Association, 1858.

the other Y', the mere reflection of Y. By this arrangement it is evident that the plain unsilvered glass thus viewed at an angle of about 45 degs.

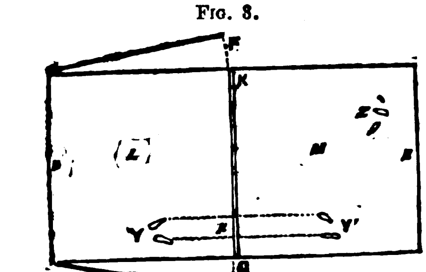
Fig. 2.



has all the properties of a mirror, but, owing to its transparency, two figures are seen possessing little or no distinguishable difference between them. Of course a person placed at Z sees only the figure Y; but as a piece of acting he may, under proper arrangements of a suitable stage, approach the situation apparently occupied by Y', and thus indicate to spectators placed at A any pre-arranged dramatic scene requiring Z to be in correspondence with the visionary figure Y'.

In using the apparatus, the flap H must be open, but I may be shut, being mostly useful to get admission for inserting or withdrawing the screen or the figures. The flap J may be closed or opened to regulate the admission or exclusion of

Fig. 3.



light. The two doors, F, G, may both be wide open, though one is generally sufficient, provided it is turned as direct as possible to the light. A mirror placed at an angle close to the opening F or G will assist the illusion by illuminating the figure Y, and thus heightening the effect of the reflection Y'.

If two geometrically proportionate figures, as spheres, cubes, or the like, be placed in the situations Y, Y', then the image at Y' will be a vision and a substance combined, as will at once appear by slightly moving the substantial body in either compartment, L or M. Let the duplicate figure be a box, and then the spectator might observe the apparent anomaly of the same box being opened and a substance taken from it and replaced either by a substantial or a visionary actor. When the compartment M is lighted up no vision appears, but, the light being made gradually to fade and disappear, the vision might seem life-like as at first. As it is evident that the right hand of the vision is the left hand of the actor in the compartment L, all his acts requiring the right would have to be performed with the left hand, to appear natural to the spectator. It is also requisite for ensuring a good effect that no solid figure in the compartment M should come before or behind the visionary image, as its transparency would at once become evident; but, if anything of the kind is desired, then the background figure or object should be placed behind the actor Y, and become with him also visionary. In this way a white screen placed behind the actor Y will allow his shadow to appear on it, and give great force and solidity to his reflected figure or vision at Y'.

TIME SIGNALS AND CHRONOMETERS.

By Mr. James Mather, of South Shields.

In the earliest ages the mariner had no means of discovering longitude; and, once on the broad ocean, his distance from land, or his whereabouts, was an enigma. Even after the compass was known, the voyages of European navigators, up to the end of the 15th century, seemed little better than coasting voyages along the shores of Europe and the Mediterranean, and even round the African continent and the Cape to India.

At the time of Columbus, longitude, though better understood, yet relied on imperfect observations of the stars with very imperfect instruments, and afforded to the mariner not much increase of knowledge, and at length brought up the great question of ages. For upwards of three centuries it was the great practical difficulty of navigators—the source of abundant errors, and often of disastrous wrecks. Columbus himself seemed lost in his erroneous views of it, which affected his westward course and his principal conclusions, corrected long after by better knowledge and experience.

In the beginning of the 16th century, the pervading ignorance on this subject induced learned men to devote themselves to the teaching of nautical science, and the modes of obtaining astronomical longitude. All the maritime States became deeply interested, and Spain and Holland especially offered large rewards for the discovery of the best mode of ascertaining it. Now, the great discoverer, Galileo, entered into the arena, and by the power of his telescope and other means, in 1610, helped forward the great question. He lucidly laid down the true principles of it—using Jupiter and his four satellites as the European clock, to strike the hour, and mark the time, in heaven, for earth. Thus, far into the 18th century, rested the position of the question of longitude. England, from her frequent losses at sea, both in the navy and mercantile marine, then became roused to its importance; and her Parliament, on the presentation of an influential petition, put itself in motion. This petition stated that the discovery of a good method of finding the longitude would "prevent the loss of abundance of ships, and lives of men, as it certainly would have saved Sir Cloudesley Shovel's fleet" (on its return from its attack on Lisbon), "had it then been put in practice." Upon this, Parliament, the same year (1714), passed an Act for the appointment of a Board of Commissioners for Longitude, offering large rewards for the discovery of the best method of finding it; and Queen Anne herself took great interest in the subject. A great nautical impulse was thus given; and at last George III. was affected by it, and offered £20,000 for the same purpose.

During this period, Mayer's executors obtained a reward for his lunar tables, teaching nautical men, with astronomical certainty, the reading of the hours, the minutes, and seconds of the celestial clock, by the movements of its pointer, the moon among the stars. To examine this clock with accuracy was the difficulty. The single-image sextant at sea was imperfect and unmanageable. Hadley, in 1740, with a sextant of two reflectors and its double image, gave to seamen a true astronomical indicator of the exact position of their local habitation. This instrument still continues to them most important for the astronomical rating of their chronometers, and for giving confidence where doubt would often be shipwreck and death.

At length appeared on the scene a simple Yorkshire carpenter, with an acute and exact mind, working in silence, as great men and great discoverers ever do; and suddenly, in 1764, he announced the invention of a chronometer, the labour of his life, that afterwards became the prototype of all chronometers. It was taken to Barbadoes and back, and gave the true longitude throughout, within a quarter of a degree. He received the £20,000 reward; and we now reap the benefit of his labours. It settled the vexed question, and is now the mariner's guide. His chief improvements or principles for his chronometer consisted, as most know, in "the detached escapement" and "the compensation balace." The vibrations of the first constituted the equations of time, unaffected by the machinery of the chronometer. The second protected from irregularities of the change of temperature, and was attached to the balance spring—afterwards to the balance itself, by Le Roy and Arnold.

Greenwich Observatory, with the accomplished Astronomer Royal at its head, now gives forth the true time, received from astronomical data that never err, and then, demonstrating it daily to the eyes of men, flashes it on lightning wings to all parts of the kingdom, for the use of mariners and others, whose lives depend upon it, and whose property, as well as that of maritime England, afloat on the oceans of the world, are secured by it from danger.

Greenwich, then, is the polestar of longitude. The power to observe it in every part is an individual and national interest. The Tyne, inferior to no port, requires that it should be done here, for the sake of its interests and the honour of its jurisdiction. A ship's chronometer is only useful when it is in exact accordance with Greenwich time, and exactly rated. If so, it is safety of way to the ship; if not, it is a false guide, a delusion, and a snare. The importance, therefore, to chronometer makers and commanders of ships of an easy reference to Greenwich time, is palpable and undeniable. Chronometers in their delicacy are not unfrequently disturbed in their rates, even by the change from the room of their makers to the cabin of the ship. "In a large majority of cases, these discordant results," says the able astronomer of the Liverpool Observatory, in his last report, "are not so much from the difference of quality of the instruments, as from the method which is almost invariably employed of obtaining the rates on shore, and calculating the errors on Greenwich mean time at sea." Whether these errors arise from change of temperature, by which even the best chronometers will be affected, and give errors of from one to two seconds daily in a change of from 30 to 40 degs., or from the irregular motion of the vessel, or some other cause, seems not yet ascertained.

The energies and acuteness of our astronomers and mechanicians, which have already eliminated nearly all causes of error from this wonderful instrument, will doubtless eventually detect and remedy what may be left. The "Nautical Almanac," which is a gigantic work of astronomical observations and calculations, giving the relative positions of the sun, earth, moon, and stars, four years in advance, enables the mariner to rate and correct his chronometer at sea, when the state of the time and the weather will permit. In storms, however, in thick darkness, and in obscured heavens, these observations cannot be made; and as a few seconds fast or slow in the chronometer may be shipwreck and death, it is clear enough that the best adjustment and rating of it should be done on board ship. It was stated by the British Association in 1837 that the best chronometers differed sometimes from each other two minutes of time, and they added, that "these two minutes might cause a wreck." A case will illustrate this:—A ship left the Tyne for South America last year. The chronometer was rated in the usual way, and the recorded rating was given as one second five-tenths slow. The time of the chronometer was trusted to. However, after thirty days at sea, a lunar observation was obtained, when the chronometer was found, instead of losing time as given, to be gaining eight-tenths of a second daily. Here was an error of sufficient gravity to have caused a wreck, had this vessel, thus directed by a treacherous guide, trusted in it. Thus the absolute necessity of an opportunity for an appeal to the true Greenwich time by every commander of a ship proceeding on a foreign voyage is quite evident. The Tyne sends forth from her busy port more laden vessels than the Thames. Upwards of 20,000 leave her harbour annually, of which a large portion go to foreign ports, and necessarily require exact knowledge of Greenwich time for longitude. All the great ports—the Thames, the Forth, the Clyde, and the Mersey—already possess time balls or signal guns, falling simultaneously with that at Greenwich, or calling in a voice of thunder, or flashing forth to the eye of the deep-bound mariner the grand truth by which his course is to be guided. The practical advantages of time signals it is not, perhaps, necessary much further to develop. They are, however, well set forth by the following extracts of communications from scientific and practical men of eminence:—

"There is no doubt," says the Astronomer Royal, in a note to me of the 16th of January last, "that a public time signal of authoritative character is a very great convenience to all classes of persons whatever—greatest of all to those persons who have to use chronometers showing accurate time."

"With regard to the advantages of time signals for nautical purposes, there cannot be a doubt," says the astronomer of the Liverpool Observatory, June 3.

"By outward-bound vessels lying in the stream, as they occasionally do for three or four days, the Greenwich time is rated from the ball, as a check upon the rate given for the chronometers."—Messrs. James Moss and Co., May 19, 1868. These gentlemen are well known as large shipowners.

"I can say that the Board thought it desirable at

the time" (when this gentleman was a member of the Marine Committee), "and I was informed that the time ball was used by captains of sailing ships, and I have never heard any opinion given against it since it was established."—William Inman, Esq., manager of the New York and Philadelphia Steamship Company.

"The captain or chief officers could always check the error given" (that is, in the rating) "by the time ball, after the chronometer was taken on board."—Messrs. Hornby and Son, the largest chronometer makers in Liverpool, 1863.

"They have no doubt that ship captains generally take advantage of the time ball."—Messrs. D. and C. M'Iver, Liverpool, managers of Cunard's lines of American steamers, and large steamship owners, May 19, 1863.

"We beg to say that our chronometers are usually sent ashore to be rated, in the first place, because of the vibration produced on board by the almost constant working of the steam-winches in loading and discharging cargo; and, secondly, because the time ball is not easily seen from the dock where the steamers load. Vessels, however, which lie a day or two in the river before proceeding to sea, escape these disadvantages: to such the time ball is a great boon, and by them is extensively used."—Messrs. Bibby, Sons, and Co., Liverpool, most extensive steamship owners, and of great experience.

Why not such an advantage for the Tyne?

The River Tyne Commissioners, deeply interested in the maritime operations of their important river, with its 400,000 registered tons of shipping, the eleventh part of the whole of the United Kingdom, had their attention called to this subject in 1859, when a committee of its body was appointed to investigate the subject. An interruption of this investigation occurred for about three years by some unforeseen causes; when, again, the Commissioners last year re-appointed the committee for the same purpose. In such investigation, we were favoured with the able advice and assistance of Professor Airy, who, with the same adaptation of energy and power by which he laid the basis of measuring and weighing distant worlds at the Harton Pit, and adopting a mode for preventing loss of time in chronometers, fully developed to them the advantages, and pointed out the practical facilities of this great disideratum for the Tyne.

The committee had under consideration a suggestion that a time ball should be placed on the High Level Bridge, and a signal gun on the old Norman keep of Newcastle, which was considered to be sufficient for the purpose of indicating Greenwich time to the upper reaches of the river, and that either a ball or gun near Whitehill Point, to command the docks and harbour, which sometimes contain more than twelve hundred ships, would be enough for the diffusion of this true knowledge. The brilliant and successful experiment performed by the Astronomer Royal of Scotland, Professor Piazzi Smyth, at Newcastle, on the 17th of August, is sufficient proof of the easy adaptation of both ball and gun.

Mr. John Hewat, of Edinburgh, was the first to propound the advantage of a signal gun; and Professor Piazzi Smyth, with that penetration which distinguishes him, at once perceived its advantages, and, calling in the aid of Messrs. Ritchie and Sons, they proceeded with the *perfervidum ingenium Scotorum* which distinguishes their country, to effect its successful execution.

The Commissioners of the Tyne having obtained opportunities of examining the skilful arrangements at Edinburgh, they there found that, by the pendulum regulator of Mr. Jones, of Chester, the clock at the castle of Edinburgh was made to pulsate with the astronomical clock of the Observatory at the Calton Hill, 4,000 ft. away. At the same time, by the ingenious clock-trigger of Messrs. Ritchie, the 24-pounder at the castle was discharged at the same instant as the time ball fell at Calton Hill, marking Government time. Daily the booming and flash of the time-telling gun from the castle-rock of Edinburgh thunders and gleams over that great city and across the broad waters of the Frith of Forth, amongst its deep bays, and for many miles throughout the surrounding country. When its instant flash cannot be observed, its sound is a true guide to mariners; for by the law laid down by Herschel, that the velocity of sound, in a temperature of 62 deg., is 1,125 ft. per second, and with 1·14 ft. difference for every degree of variance from 62 deg., adding for an increase, deducting for a decrease, the exact moment of discharge is fixed. This practical lesson cannot be lost upon the promoters of this great object on the Tyne. All that are required for those operations, with certain additions for the signal gun, are expressed by Professor Airy, in his letters to the Tyne Commissioners, thus:—"The information given to you," states the Astronomer Royal, "is correct, that, at ten and at one time signals, equally accurate, are sent from Greenwich Observatory, with no interruption except that of a relay at Lothbury, every day. From our best companies direct with Edinburgh, it appears that, where the metallic circuit is complete, the whole time occupied in the passage between Greenwich and Edinburgh is less than the 1-20th of a second"—(the action of the relay cost, on one occasion, the 1-50th of a second). "If wires were always in good order and dry, there would be no difficulty in dropping the time signal by direct action at Greenwich. But, viewing the chance of failure of these saving circumstances, I should recommend that the Greenwich current should be used to give signals only to the telegraph office, by which the error of a clock, No. 1, stationed there, would be ascertained, and with this knowledge another clock, No. 2, would be adjusted, and this No. 2 clock would automatically drop the signal. You may take the hour or hours you like best. The usual hour (following the example of Greenwich, which was fixed by office convenience), is 1 o'clock p.m. You had better come here in the morning, to include 1 p.m. in your visit, and we will mention other points." To carry out these suggestions of Professor Airy, according to Mr. Latimer Clark, the experienced engineer of the Electric and International Telegraph Company, it would require to make a junction between the Greenwich Obervatory and the selected sites or stations at Newcastle, and that near Whitehill Point, costing abont £160; two time balls, costing each about £110, equal to £220; a very good clock at each station, each £25, equal to £50; the maintenance of wires between Newcastle and Whitehill Point, £10; the charge for daily electric communication, per annum, £40; total, £480. After which, £100 a year, or thereabouts, may be taken as the cost of keeping in repair and working these time signals for the Tyne.

The signal gun also contemplated, and already so completely demonstrated, will doubtless add something to the cost. The Tyne Commission, however, with the means and appliances at their command, have great facilities for successfully and comparatively inexpensively carrying out this great object. To the Astronomer Royal, Professor Piazzi Smyth, and other scientific men, this important question may be well left for their better knowledge and experience to elucidate.

CLARK'S IMPROVEMENTS IN PROJECTILES FOR ORDNANCE.

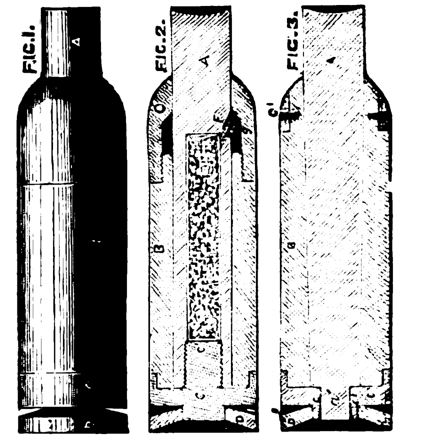
Letters Patent have been recently granted to William Clark, engineer, London, for an invention which relates to what are technically known as "sub-calibre" shot and shell—that is to say, shot and shell of a calibre less than that of the guns from which they are intended to be fired.

It consists, first, in the combination of a bolt or elongated shell of iron or steel, having a cutting face and a surrounding casing of wood or other light material; secondly, in a rear cap of metal, so applied in combination with the bolt or shell and the wooden casing as to serve as a means of holding the wooden casing, as a means of attaching the packing device, and as a means of supporting and guiding the rear end of the projectile in the bore of the gun; thirdly, in a front cap of metal, so applied in combination with the bolt or shell and the wooden casing as to serve the purposes of holding the forward end of the casing, of supporting and guiding its front end in the bore of the gun, and of effecting the explosion of the charge of the shell by resistance against the surface of the body penetrated by the shell itself.

In the accompanying drawing, fig. 1 is a longitudinal outside view of a shell constructed according to this invention; fig. 2 is a central longitudinal section of the same; fig. 3 is a central longitudinal section of a shot illustrating a modification of the invention. Similar letters of reference indicate corresponding parts in the several figures.

A is the bolt which forms the body of the shot or shell, made of cast steel or of iron faced with steel at its front end; and if intended for operating against metallic armour, its face is made concave, as shown in figs. 2 and 3, to produce a sharp cutting edge. For a shell, the exterior of this bolt may be made perfectly cylindrical, as shown in fig. 2, as the cavity for the charge may

FIG. 1. FIG. 2. FIG. 3.



be so arranged as to bring the centre of gravity nearer the front end; but for a solid shot, the bolt is tapered towards the rear end for about two-thirds of its length, as shown in fig. 3, to bring the centre of gravity to the desirable point. B is the casing of wood or other light material surrounding the bolt A, and extending from the rear nearly to the front end thereof, having a periphery of cylindrical form to fit the bore of the gun. This casing may be made to fit the whole space between the bolt and the bore of the gun, as represented in figs. 1 and 2; or for projectiles to be used in guns of large calibre may for the sake of ligthness be composed of staves secured around the exteriors of bands which encircle and fit snugly to the exterior of the bolt. C is the rear cap, made of malleable iron or other metal fitting over the rear end of the casing B, as shown in figs. 2 and 3. D is the cup-shaped annular disc of copper or other soft metal fitting over a projection c upon the rear face of the cap C, which projection is made of angular or irregular form in its tranverse section, to prevent the disc D turning on it. The cap C performs three functions—to wit, holding the rear end of the wooden casing, supporting and guiding the rear end of the projectile within the bore, and constituting the means for the attachment of the packing disc D. I represents hemp, candle-wicking, or other fibrous material, thoroughly saturated with a composition of tallow, black lead, and sulphur, coiled between the disc D and cap C, and when compressed between the said disc and cap it expands radially in all directions so as to assist the disc D in closing the windage. The composition above mentioned is likewise very beneficial in lubricating the bore of the gun and preventing heating and scaling. In the illustration given in fig. 2, the cap C also constitutes the means of closing the orifice through which the chamber of the shell is charged with explosive material, for which purpose this cap is formed with a projection c^1 adapted to screw into the chamber, the pitch of its thread being in the reverse direction to that of the lands or rifle grooves in the gun in which the projectile is to be used. The cap C may be attached to a solid shot by fitting it over a stem a^1 provided on the rear end of the shot and securing it by wedges c^2, as represented in fig. 3, or by upsetting or rivetting the said stem at the back of the cap. F (fig. 2) is a nipple, secured in an oblique position in the side of the shell. G is the front cap of metal, having a portion of its exterior cylindrical end of a size to fit the bore of the gun, and having in its front part a central opening to fit the bolt or body A so that it may turn freely therein. In the rear portion of the cap there is a screw thread to enable it to be screwed on to the front end of the wooden casing B, as shown in fig. 2, that it may hold the said end of the said casing in place, and support and guide it in the bore of the gun. The cap covers the nipple F. In the case of a solid shot, the forward end of the wooden casing may be held

by a simple metallic band slipped over its exterior and secured by screws V,V, as shown in fig. 3. The operation is as follows:—

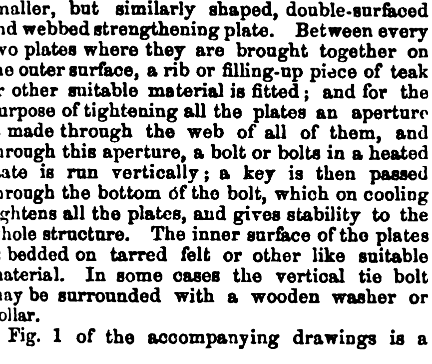
The charge having been inserted in any suitable form or manner, and a percussion cap put on the nipple F, and the cap G having been adjusted to a suitable position with respect to the nipple, the shell is ready for placing in the gun. The first effect of the carrying charge in the gun is to expand the cup-shaped disc D, forcing it and the packing and lubricating material I into the rifle grooves, and effectually closing the windage, and insuring a spiral motion of the shell as it is impelled forward through and from the bore, the screw C¹ being, in the meantime, tightened by the rotary motion received from the packing disc D. Owing to the great area exposed to the explosive force of the charge of gunpowder in the chamber of the gun in proportion to the weight of the shell, a very high velocity is produced, as is well known to be the case with sub-calibre projectiles. On striking any resisting body, such as metal armour, the small diameter of the bolt A causes its concave cutting face *a* to enter with great facility, and it passes in until the front of the cap G reaches the surface of the said body, and is arrested, when the momentum of the bolt continuing, carries it forward through the said cap G, and into the said body, the percussion cap on the nipple F is driven against the oblique inner surface *g* of the said cap G, the angle of which is such as to strike evenly upon the top of the percussion cap. After having done its work of communicating fire to the exploding charge within the shell, the nipple F is crushed or broken off in passing through the cap G, and the bolt A is carried by its momentum into and through the armour, and at the same time exploded therein. The shell B is crushed and dropped or thrown off with or before the cap G. The nipple F may be placed in any suitable position to effect the explosion of the shell at any period or degree of penetration. The operation of the solid shot only differs from that of the shell in its not exploding.

BELL'S IMPROVEMENTS IN ARMOUR-PLATING.

THIS invention, patented by Richard Bell, architect, Gracechurch-street, consists in securing to the iron frames or ribs double surface plates, that is, plates somewhat similar in form to ordinary rails for railways, the web or beam connecting the two surfaces being of a depth varying with the requirements of the ship; the inner surface of the plates is recessed so as to receive between every two plates an intermediate and smaller, but similarly shaped, double-surfaced and webbed strengthening plate. Between every two plates where they are brought together on the outer surface, a rib or filling-up piece of teak or other suitable material is fitted; and for the purpose of tightening all the plates an aperture is made through the web of all of them, and through this aperture, a bolt or bolts in a heated state is run vertically; a key is then passed through the bottom of the bolt, which on cooling tightens all the plates, and gives stability to the whole structure. The inner surface of the plates is bedded on tarred felt or other like suitable material. In some cases the vertical tie bolt may be surrounded with a wooden washer or collar.

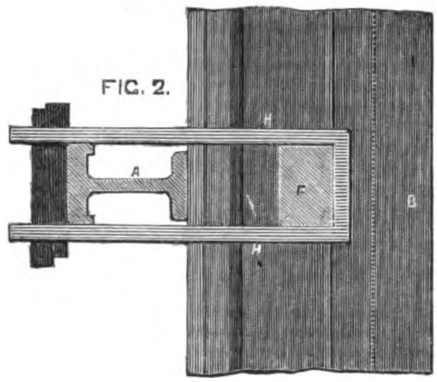
Fig. 1 of the accompanying drawings is a

FIG. 1.



section of a portion of a ship's side, armour-plated or protected according to this invention; fig. 2 is a section through the line *a*, *b*, of fig. 1. The patentee secures to the iron frames or ribs A of the ship plates B, somewhat similar in form

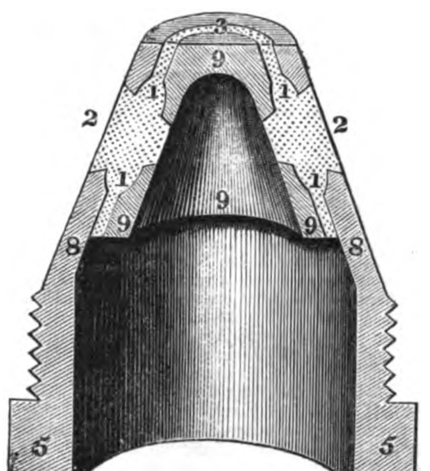
FIG. 2.



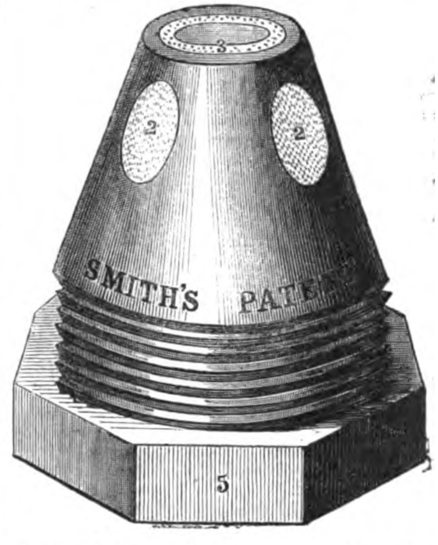
to ordinary rails for railways, the web or beam C, being of a depth varying with the requirements of the ship. The inner surface of these plates is recessed, as shown, to receive between every two plates an intermediate and similarly shaped strengthening plate D. Between every two of the plates B, where they are brought together on the outer surface, is fitted the rib or filling-up piece E, of teak or other suitable material, securing all the plates. Iron collars or clips H are placed at intervals round the bolts F, and keyed to the inner side of the frames or ribs A.

JOHN SMITH'S FUSIBLE PLUGS.

THIS invention consists in forming the body of the plug (which has usually been made in one piece screwed direct into the crown of the boiler furnace) in two parts, so that the one part containing the plug may at any time be removed without disturbing the part which is screwed into the boiler. In some cases, these plugs are



inserted or fixed entirely from the inside of the fire box or flue without the necessity of entering the boiler for the purpose. The patentee forms that part of the plug which is intended to be blown out by the fusion of the soft-holding metal, and the hole in which it is placed, in such manner as to present a greatly increased resistance to the blowing out of the plug by pressure alone. This is effected either by cutting grooves or screw threads in the hole, and similar grooves or threads in or upon the blow-out piece, and running the fusible metal between, so that the whole depth of the fusible must be sheared for pressure alone to have the effect referred to. Otherwise, instead of turning grooves in, or screwing the two parts, as described, the patentee forms each of them with a recess, so that the two, when placed together, will form a cavity in which the fusible metal may be run and which will effect a similar object. In the accompanying drawings—1 shows fusible metal between the external and internal cones; 2, fusible metal filling up the perforations of both cones; 3, ditto, shown



at the top between the two cones; 4, two-inch gas thread, fitting into boiler-plate beneath the water. This plug is, perhaps, the best of its kind, and is getting into extended use.

TRIAL OF STEAM FIRE-ENGINES.

AT the half-yearly inspection of Mr. Hodges' Fire Brigade, which took place at Lambeth, on Thursday week, some experiments with Messrs. Merryweather and Field's steam fire-engines, "Torrent" and "Sutherland," were undertaken; the most interesting feature being a trial of the time required to fill a tank holding 448 gallons. Steam was got up first in the "Torrent." The fire was laid in the ordinary manner, without any attempt at providing for a racing trial; the wood, consisting mostly of green cask hoops, far from dry. The match was applied at 41 minutes past 2 o'clock. The gauge moved in six minutes, and the times and pressures were as as follows:—In 7½ min. the gauge showed 5 lbs.; in 8¼ min., 10 lbs.; in 8 min. 35 sec., 15 lbs.; in 9 min. 3 sec., 20 lbs.; in 9 min. 35 sec. 25 lbs.; in 9 min. 40 sec., 30 lbs.; in 9 min. 50 sec., 35 lbs.; in 10 min., 40 lbs.; in 10 min. 12 sec., 45 lbs., at which pressure the engine started, throwing a very fine jet to varying distances and heights. A 1¼-in. nozzle was then fitted to the end of a long tank, capable of holding 448 gallons, which the engine filled in 2 min. 5 sec., under an average head of about 14 in.

Steam was then raised in the "Sutherland." This engine has been purchased by the Admiralty for the use of Devonport Dockyard. The match was applied at 3.30, and the first steam obtained in 3 min. 45 sec.; 5 lbs. in 4 min. 45 sec; 20 lbs. in 6 min. 20 sec.; 40 lbs. in 7 min. 45 sec.; and 80 lbs. in 8 min. 45 sec., at which pressure the engine started, throwing 1¼-inch jet to a height of about 150 ft. with great steadiness, the pressure in the boiler being 95 lbs., and in the air-vessel 80 lbs. Subsequently, four 1-in. jets were fitted to the hose, and with a pressure in the boiler of 115 lbs., and in the air-vessel of 50 lbs., some splendid work was done. Great trouble was experienced through the trials from the continued bursting of the leather hose pipes. A horizontal jet was thrown through a 1¾ in. nozzle to a great distance.

The 448-gallon tank was then filled, in 47 seconds, through a 1¼-in. nozzle, under a pressure of 100 lbs. in the air-vessel, and 115 lbs. in the boiler, steadily maintained. Steam was kept in both the engines with great ease, and more moderate firing than we expected, with the Crystal Palace reminiscences fresh in our memory.

TRIAL TRIP OF THE TWIN-SCREW STEAMER "CERES."

The first trial trip of the new twin-screw steamer "Ceres," built by Messrs. Dudgeon, of Blackwall, took place on Tuesday last; the vessel running from Tilbury to some distance below the Mouse Light and back. The following are some of the principal dimensions of the ship and engines:—The length of the ship is 176 ft., beam 21 ft., depth 13 ft. 6 in., burthen 500 tons. She is fitted with independent double-cylinder engines, cylinders 26 in. diameter and 21 in. stroke. Nominal collective horse-power 120. The average speed attained was 14½ knots per hour.

On the return to Tilbury, some experiments on her powers of manœuvring were gone through, with the following results:—First—helm a-port, port engine ahead, starboard astern—revolved on her centre in 2 min. 15 sec.; second—helm shifted and engines reversed—revolved opposite way on her centre in same time; third—whilst turning, the engines were suddenly stopped and reversed, and the counter-motion was instantaneous; fourth—starboard engine stopped, port going ahead, helm a-port—she performed the circle in 4 min.

Among those present were Admirals Sir E. Belcher, C.B., George Goldsmidt, C.B., John Duntze, and Captain Symonds, R.N., Messrs. Kitson, sen. and jun., and several other scientific gentlemen.

IRON FOR MOULDING.

In foundries where the castings are made of pig-iron, the qualities of which are well-known, the task of managing the cupola or melting furnace, and running the metal, is comparatively easy. But in foundries where cheap castings are produced and a variety of work manufactured, the management of the melting furnace is more difficult, and much practical skill is necessary to mix and heat the iron. In such foundries large quantities of cheap fusible scrap-iron, in the form of old pots, grate-bars, retorts, &c., are necessarily used. The qualities of such iron differ greatly. Some scraps are hard, others soft, and most of them contain much oxide and impurities. Old gas retorts are almost as difficult to fuse as wrought iron, and they generally require to be mixed with some iron that melts easily and flows freely. Some kinds of scrap-iron require a flux to unite with the oxide and impurities. Oyster shells are usually employed for this purpose. They are chiefly composed of lime, and by uniting with the impurities they form a black slag, which floats upon the surface of the molten metal, and has to be removed by an iron rod, which is stirred into the ladle, the slag adhering to it like glass to the iron rod of a glass-blower. A very intense heat is also required to fuse certain kinds of scrap-iron, and much care must be exercised in selecting coal of the proper quality for this purpose. The graphine or hard carbon which forms in the interior of iron gas retorts, is the best known substance from which to obtain an enduring heat of high intensity in a cupola. For melting some fractious kinds of scrap-iron, some moulders would give double the price for a ton of graphine that they would for the same weight of anthracite. This substance has now ceased to be used, because it has ceased to be made, owing to the general substitution of clay for iron retorts. A suitable substitute for it would be a great benefit to many foundry establishments. Old scrap-iron is more commonly employed in some foundries in the vicinity of cities, because it can be obtained in large quantities in such situations. We received a communication lately from the proprietor of a foundry in a country village, who stated he had been unable to use scrap burnt iron, such as furnace bars, &c. Old furnace bars of locomotives are much prized by some of the moulders in the city, as they are generally made of good iron, and are not so much burnt as other grate bars. Burnt iron, as it is called, is difficult to melt; it requires a flux of oyster shells or lime, and an intense heat in the cupola. For fine castings, scrap iron cannot be used with safety, unless the scraps are of uniform quality and their character well-known. An experienced moulder is competent to form a very accurate opinion of the nature of iron, from an examination of its grain, but the most skilful admit that there are so many different kinds of iron, they are frequently puzzled, and make mistakes as to their fusibility and capacity of flowing into moulds.—*Scientific American.*

STEAM PLOUGHS AT WORCESTER.

Continued from page 687.

Before proceding to notice machinery on the moveable-engine system, I would add a word of caution respecting the employment of second-hand thrashing machines for steam tillage. A 7 or 8-horse engine, working at 45 lbs. pressure, is quite unable to perform the work ordinarily expected of a steam cultivator or plough. On land where 5½ in. deep ploughing (with a horse-plough) gave a fair draught for a pair of horses, Messrs. Morton and Harrison found the draught of Mr. Smith's 3-tined grubber, when taking 30 in. breadth at a time, 5 and 6 to 6½ in. deep, to be 12 up to 19 cwts.; and again, the draught of Messrs. Howard's 3-tined grubber, when taking 3 ft. breadth, 4 to 5½ to 6½ in. depth, was 12 up to 21 cwts. At a pace of 3½ miles per hour, these cwts. represent so many horse-power; far beyond the nominal horse-power of the aforesaid thrashing-engine. By driving from, say, a 3½ ft. sheave, instead of from the 5 ft. fly-wheel of the engine, the obtainable draught may be increased—of course at a corresponding sacrifice of pace in the implement and of the acreage done per day. But if the engine boiler be sound and strong, and the fire-box well strengthened with extra "stays," the engine may be safely worked up to 60 lbs. pressure, giving out proportionally more than her nominal power. Engines expressly made for steam cultivation are extra strong, capable of working up to double their nominal horse-power; and it is with these that expeditions and therefore cheap cultivating and ploughing are accomplished.

Coming now to moveable-engine forms of apparatus, I will first refer to that of Messrs. Coleman and Sons, of Chelmsford. The engine travels at intervals along one headland, always opposite the end of the work; and from two coiling drums upon a longitudinal axis at the side of the boiler (and unavoidably of too small a diameter for the best usage of the rope), two ropes are led side by side across the field to two separate and independent implements. These are 5-tined cultivators, with tines that can be instantly set in or out of the ground. Each implement in turn is alternately hauled in work towards the engine, and then pulled backwards out of work to its next starting point; but each traverses only half the length of the field, one beginning where the other finishes its furrow, midway between the engine and an anchored pulley on the far headland. This arrangement (proposed by myself before the Society of Arts in 1858) enables the use of only a very slight anchorage, and a light rope around it, extending the length of the field, and connecting the two implements together; seeing that the working strain is only exerted directly between the implements and the engine. This thin rope is taken up or let out for varying lengths of furrow, by a drum upon one of the implements; and a self-acting brake upon the engine preserves the tightness of all the ropes, necessary for holding them off the land upon the rope-porters. Owing to the implements being single instead of double, they occupy less room and leave narrower headlands; working up to the engine, they can dispense with signalling; and there being neither windlass nor travelling anchorage, the whole tackle is removed from field to field by the locomotive engine, and set to work in a very short space of time. The grubbers make good work, and purchasers of the apparatus speak highly of its performances; but the system has not at present been adapted to turn-over ploughing.

Mr. John Fowler, of 28, Cornhill, and of the Steam-Plough Works, Leeds, has three distinct forms of steam-cultivating machinery; all based, however, upon the use of the moveable engine. In the simplest, an endless wire-rope is distended between a "clip-drum" under the boiler of a locomotive engine on one headland, and a pulley upon a self-travelling anchorage upon the other headland. The groove of the drum, being made of nipping pieces in pairs, pinches the half-turn of rope in exact proportion to the strain or draught, and may be set at pleasure to any degree of pressure; so that the rope is held without slipping in the grip of a 10, 12, or 14-horse engine, working up to double its nominal power. But though there is considerable wear of the clipping-pieces (which are very easily and cheaply renewed), it does not appear from experience that the rope itself suffers any more than it would from careful coiling upon a winding-drum. By means of a "taking-up" or "slack" gear upon the implement, the pulling rope employs about one-sixth part of its strain in maintaining a considerable degree of tension in the back or return rope; and by this self-acting contrivance, the entire length of rope is held up clear off the ground, riding over the friction-rollers of the rope-porters. The economy of motive power thus obtained is so great, that only trifling improvements in this direction remain possible to future inventors. It has been shown from Messrs. Morton and Harrison's experiments, that, out of a total draught of 23½ cwts. due to the work (with a 350 yds. furrow), 1 cwt. is consumed in moving the rope and pulley, and ⅓ of a cwt. more in moving the anchorage forward; leaving no less than 27 and 1-6th cwts. (or 95 per cent. of the total draught at the clip-drum) engaged in hauling the implement. And, deducting the average draught of the plough when out of work—2⅓ cwts.—the result is that 24½ cwts. (86 per cent. of the total draught) are actually applied to the severing and upturning of the soil. And considering further how largely the peculiar sources of friction and cohesion in horse-drawn implements are avoided in the steam plough and steam grubber (so that only minor improvements can be made either in the implement or the hauling apparatus), we see that little room can possibly remain for some novel machine which theorizers are expecting will one day accomplish two or three times as much tillage by the same expenditure of power. Saving of labour, too, can hardly be an important item in any future invention; seeing that to work this apparatus of Mr. Fowler requires only an engine-driver and ploughman, one anchor-lad, and a couple of porter-boys; of course, with the addition of cartage of fuel and water.

To accommodate customers who prefer a lower-priced machine, at the sacrifice of having to remove the engine, separate windlass, anchorage, &c., by horses, Mr. Fowler places a clip-drum with the requisite toothed-wheels and a driving-rigger, in a self-travelling carriage-frame, which has cutting flanges attached to its wheels to prevent sidelong slipping in the direction of the ropes, these flanges being removed when shifting from field to field. A common portable 8 or 10-horse engine, temporarily attached to this drum-carriage by a sort of iron shafts, follows it along the headland; a V-grooved rigger on the crank-shaft driving a similar rigger on the drum-carriage by means of a peculiar endless chain. This chain is composed of hard-wood blocks, wedge-shaped to fit the V-groove, and connected together by iron link-pieces. It conveys the whole force of a powerful engine, without slipping, no matter how loosely the chain may hang, and with large allowance for different angles of position of the two riggers; and the wear is probably very trifling indeed.

A third set of Mr. Fowler's machinery consists of two locomotive engines, one on each headland, hauling the implement to and fro, by means of a single length of rope, alternately wound and unwound by ordinary coiling drums, one beneath the boiler of each engine. A beautifully ingenious and very simple contrivance (in which is employed a travelling pinion gearing with two differential spur-wheels, demanding diagrams for an explanation) regulates the wrapping of the coils; but winding upon a drum with vertical axis can never be so neatly done as upon a drum with horizontal axis, in which case the coils are not liable to drop over one another when loose. As the rope can feed on to the drums at any angle of direction, and the engines (following any irregular line of hedge-row) take up or let out rope for varying lengths of furrow, without any hindrance or any attention on the part of the men; and, moreover, as there is neither windlass nor anchorage of any sort to be shifted or set down (so that after finishing a field, the engines can move off at once with rope and implement, and without the assistance of any horse at all, instantly commence work in another field), this double engine arrangement is admirably calculated for districts of irregular-shaped inclosures, and especially for working on hire. Of course, the slack half of the rope is only imperfectly carried; but then, all the rope out at once is only of the same length as the furrow. In economy of performance, unless the number of removals be excessive (as in contract work), the double-engine system falls behind that of the single-engine and anchor-

go; and it is, at the same time, a far more heavy investment.

I need not describe Mr. Fowler's implement. The 3-furrow or 4-furrow plough, balanced upon a pair of large-sized wheels, can be fitted up with cultivating-tines, or the plough-share can be used with short prong mouldboards (or "digging breasts"), which perform much more effectual tillage than any other cultivating-tines whatever. Trench ploughs, subsoilers, or double-breasted ridge-ploughs, may all be used on this implement. Another implement is the 5-tined or 7-tined cultivator, similarly balanced upon a pair of wheels, the tracks of which are obliterated by the tines following them. Another is a cultivator and subsoiler combined, working to a depth of 18 in. Another is a set of heavy harrows, hung in a light framing, to which the steering and slack-rope gear are attached. For working behind the plough, a 3 or 4-furrow land presser is provided, with seed-box attached; and a corn-drill is also supplied, to be worked alongside the cultivator, thus making a seed-bed and sowing at one operation.

The double-engine system is carried out in a novel manner by Messrs. W. Savory and Son, of Gloucester. A shell drum, of 6 ft. diameter, without arms or spokes, incloses the body of an engine-boiler,—revolving upon three pairs of friction-wheels, which are supported in brackets upon the boiler. The cylinders are placed transversely across the end of the smoke-box, over the steerage wheels; and the long crank-shaft passing inside the drum drives it by pinion and internal gear, and also by means of a screw or worm gives motion (at pleasure) to the hind* carriage-wheel axle. The drum will contain 500 yards' length of rope in a single layer of coils; and a couple of guide-rollers traversing the length of the drum by means of a rotating shaft, threaded like a screw, regulate the coiling so perfectly that the rope never overlaps itself; thus avoiding any grinding or damage from acute bending. Two engines thus fitted haul the implement (a Fowler's plough or Howard's grubber, &c.) to and fro from one headland to the other; the guide-rollers deflecting the rope when the furrow is not quite at right angles to the direction of the headland; while in case of an acute angle of direction, the engine can be moved forward and steered so as to present its broadside always toward the line of work. This setting of the engine askew may not be very advantageous to a moist headland; but there is plenty of time for the operation; one engine having nothing to do but to take up its position while the other is hauling the implement. To feed the boiler with water while the engine is at rest, Messrs. Savory employ a small "donkey-engine," placed (like the steering mechanism and reversing clutches) close at hand, under the command of the engine-man. Mr. Fowler's "double" engines supply themselves with water by simply running disconnected with their drum or propelling wheels. In Messrs. Savory's arrangement the cylinders are necessarily of short stroke, giving their full power only at a high number of revolutions per minute (unless at an excessive pressure of steam); and by driving the drum directly without reducing gear, too great a speed is obtained for any implement to work steadily. Travelling at a pace of more than 4 miles per hour (5 miles per hour in light work), the implement not only makes imperfect work, but incurs great risk of damage from land-fast impediments; and, besides, a broader cultivator, at a pace of 2½ to 3 miles per hour, would waste less time owing to the few number of bouts, each with its steady commencement and slackening of speed toward the close of the journey. The facilities of the twin-engine principle are well illustrated by this set of apparatus, which, without the assistance of any horse, brought itself along 30 miles of up-and-down-hill road from Gloucester in one day, and shifted from field to field, losing but a few minutes in gathering up or leading-out rope and taking up position ready for work.

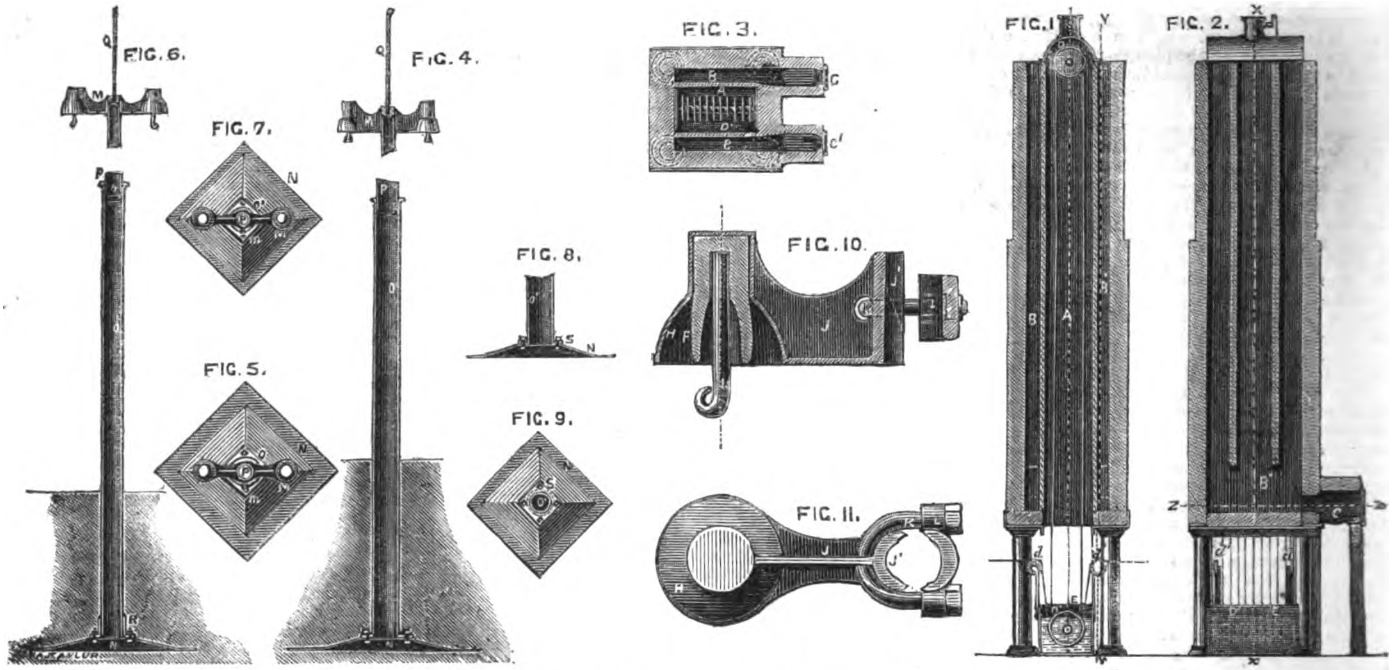
One more invention remains for notice. Mr. Collinson Hall, of Navestock, Romford, Essex, substitutes for wire-rope a chain, formed of ½-inch round steel rods, 18 in. long, coupled together by pairs of flat plates 4 in. long, with connecting rivets; and an endless chain, thus made, passes one half-turn round a pulley upon a self-travelling anchorage at the further end of the field. But the drum and pulley are polygonal instead of circular; and the link-chain is hauled by means of cog-teeth upon the drum taking into the apertures provided by the coupling-plates of the chain. The breaking strain of the plates (the weakest point) has been found to be about 14 up to 22 tons; the chain being probably stronger than wire-rope of equal weight. bility. The rods and plates of this link-chain (exhibited by Messrs. Turner, of Ipswich) present but little appearance of attrition after having ploughed 400 acres; and it is affirmed that not one rivet has yet been broken. The wear must take place chiefly on the ends of the rivets and in the eyes in which they work; but if the rivets be purposely made of softer metal, they alone will wear away, and the whole of the 2,800 rivets in 800 yards' length of chain may be replaced for some 30s. As the chain (from its sidelong rigidity) will not wrap upon a drum, it is unadapted to the stationary-windlass system, where greater economy of rope is most of all desirable; and, moreover, this necessitates a tedious unbolting and folding of sections of the link-chain for removal in a cart, instead of quickly and conveniently coiling it upon the engine-drum. Again, the chain cannot ride upon porters, owing to the excessive amount of play or hinge-action so demanded of the rivet-and-plate joints; hence incurring a very considerable waste of motive power. The comparative draught of a given length of this link-chain and of wire-rope trailing upon the ground has not been ascertained; but the weight of the present link-chain is 3 lb. per lineal yard, or from one-half up to twice more than that of the wire-rope of different sets of apparatus. Of course, it is a mere sophism to excuse the heavy drag of a rope or chain along the ground by saying that a cwt. or so more coal per day will give the extra power required; for when an engine is already working up to her full power compatibly with safety, an additional one, two, or three horse-power can be obtained only through a stronger boiler, a larger cylinder, and, in fact, by an entire engine of bigger dimensions and higher prime cost.

As applied to the twin-engine system, Mr. Hall's traction-medium deserves consideration. Instead of two 12 or 14-horse engines, each idle in turn while the other is hauling a single length of rope, he employs two 6 or 7-horse engines, both simultaneously hauling an endless link-chain and thus accomplishing as much work as engines of double the power, weight, and first cost. The back or return ply of the chain being always tight, can be mounted upon low porters; and the other ply along the track of the plough may be similarly upheld where in advance of the implement, though left upon the land where running slack. For varying lengths of furrow, a portion of spare chain is carried folded upon the implement; a hook that will lay hold of the chain at any point allowing one or more links to be left out or taken up at pleasure. I do not know why Mr. Fowler's twin-engines should not be of lower power, and work an endless wire-rope with clip-drums; thereby lightening the apparatus for a deep and sticky district, as well as sparing the contract proprietor or company several hundred pounds of purchase-money. The objection to two engines working at once is the difficulty of securing simultaneously starting and stopping; it remains to be seen how far this may be overcome,—perhaps by signal rope laid out between one engine and the other.

My account of the steam-tilling machinery at Worcester being intended to touch only upon points not fully elaborated in the Judges' Report, I leave all details of the four days' competitive field-work, merely drawing certain inferences, either from my own personal observation or from the official statistics and remarks. Comparing self-locomotive apparatus for that working a common portable engine, it appeared (in course of the trials) that the latter (if cultivating at the rate of about an acre per hour in moderate-sized inclosures) would lose more than two hours every other day in removing to fresh ground half a mile off, if 4 horses were employed for the operation; or it would require 8 horses in order to shift it about one to one and a-half hours. On the other hand, a couple of self-travelling engines would move the same distance in 25 minutes, without any horse at all; while a single locomotive engine with an anchorage would take a longer time than this, but equally dispense with the assistence of horse-flesh. Comparing the amount of labour required, we find the stationary-engine apparatus to be manned as follows:—Mr. Smith's, 6 men; Messrs. Howard's, 5 men and 2 boys; and Mr. Hayes', 4 men and two boys. The moveable engine employs hands as follows:—Mr. Fowler's separate-drum tackle, 3 men and 3 boys; Mr. Fowler's other tackle, 2 men and 3 boys; Messrs. Coleman's apparatus, 5 men and 2 boys. Mr. Fowler's, like Messrs. Savory's twin-engine plan, is worked by 2 men and 3 boys. In all cases, the labour of water-carting is additional. As regards the relative cost per acre of a given operation, I consider that no accurate test was furnished by indurated ground torn up into pieces of all sizes, and at average depths which, after the most careful measuring in a few spots, must remain open to differing individual opinions. Mr. Fowler's moveable 10-horse engine, and Messrs. Howard's stationary 10-horse engine, completed their equal plots (of less than two acres) in very nearly the same time, with about equal consumption of fuel; but the former worked five tines at once, and the latter only three. Mr. Smith's stationary 10-horse engine, with a 3-tined cultivator, working at the same depth as the other two, and making the most efficient tillage, burned somewhat more coal, and occupied one-half more time. Messrs. Savory's two 10-horse engines finished their plot in rather less time than either Messrs. Fowler or Howard's machines, but with nearly two-thirds more coal. In turnover-ploughing 1¼ acres each, Messrs. Savory, Fowler, and Howard, occupied nearly equal times. In cultivating a little over 1½ acres each at Wadborough, Mr. Smith's 10-horse tackle consumed the least coal, but took the longest time; Mr. Fowler's 14-horse engine expended both the least time and smallest quantity of fuel; Messrs. Howard's 10-horse tackle consumed a trifle more coal, and was considerably longer in doing the work; and Messrs. Savory's two 10-horse engines, while taking less time than Messrs. Howard's, burnt considerably more fuel. But the unavoidable absence of reliable dynamometrical tests, and the impossibility of assigning any exact value to the several degrees of effectiveness in the different works, forbid any minute deduction from these experiments as to the comparative economy of the competing machines. Mr. Fowler's two 12-horse engines, for instance, consumed as much coal as Messrs. Savory's, and spent more time than Messrs. Howard's—nearly as much as Mr. Smith's—in tilling about 1½ acres; but then their work done by the digging-breasts was very superior to any other in the field. It may be taken as a general conclusion that a moveable engine—working with less rope, fewer pulleys, and consequently less waste of motive power, while employing fewer workmen—performs any given process at less cost per acre than a stationary engine can; and this point together with the very low expense of all the steam-tillage done, is illustrated in the Judges' Report, where the percentage for interest and wear and tear is by no means too favourably assessed. But the reader should bear in mind that while Mr. Fowler's work with a moveable engine cost less money per acre than the work of either Mr. Smith's or Messrs. Howard's stationary engine, the difference in his favour would have been greater had the areas in the competitions been, say, 20 acres each, instead of only some 2 acres each; seeing that the additional length of rope required by the round-about system becomes a serious drawback when surrounding a large enclosure, and not perfectly carried off the ground.

At the the Worcester trials hard stiff loam was cultivated 7 in. deep by Mr. Fowler's 10-horse-power machine at the rate of 9¼ acres per day, and a total expense (without removals) of 4s. 9d. per acre; and Messrs. Howard's 10-horse-power machine worked at the rate of half an acre per day less, and 2d. per acre more money. Ploughing 6¼ in. deep, with the same set of hauling apparatus, was performed by Mr. Fowler at the rate of 7¼ acres per day, and a cost of 6s. 3d. per acre; and by Messrs Howard, at the rate of 7 acres per day, and at 6s. 4d. per acre. But by way of contrasting steam-power performance with that of horses, I must cite one or two of the most memorable feats in the moister and more suitable fields at Leeds and Canterbury. At the latter trial, in 1860, in ploughing a strong loam (which from the ascertained draught of a common plough at 6 cwts., would cost 12s. an acre if turned over by horses), Mr. Fowler's 12-horse engine, working with a pressure of 68 lbs. on the square inch, drove 4 "3 horse-furrows" at once at the rate of 11 acres in ten hours; and the total cost was computed at 4s. 6d. per acre, in stead of 12s. (the lowest price by horse-labour), though the excessive allowance of 20 per cent. was put down for interest and wear and tear. At Leeds, in 1861, Messrs. Howard's 10-horse engine scarified a strong and stubborn soil 5 or 6 in. deep, at the rate of 6¾ acres in ten hours, at a cost of 6s. 8d. per acre. Mr. Fowler's 12-horse engine scarified the same soil 7 in. deep, at the rate of 5¼ acres in ten hours, at a total cost of 7s. 2d. per acre. In land where the ploughing of a single furrow 8 in. deep required a draught equivalent to the power of 5 horses, the same engine ploughed at that depth at the rate of 5¾ acres in ten hours, for a total cost of 7s. 10d. per acre. Of course in reading these figures (as well as those of the Worcester Judges' Report) it should be borne in mind that, though ordinary wages are charged for the labour, the trained hands of exhibitors are masters of larger daily acreage than could be expected from common farm workmen.

SIEMEN'S TELEGRAPH WIRES.



SIEMEN'S IMPROVEMENTS IN SUPPORTING TELEGRAPH WIRES.

This invention, patented by Mr. C. W. Siemens, of 3, Great George-street, Westminster, consists of improvements in insulating and supporting telegraph line wires. Telegraph line wire is sometimes covered throughout its length with an insulating material, and at other times is suspended in the air from poles with insulating supports for the wire attached to the same; in the latter case, the atmospheric air is the insulating medium surrounding the conductor.

In forming a continuous insulating covering upon a conducting wire, the patentee employs the juice or milk extracted from the india-rubber or gutta-percha trees, or varieties of the same. For this purpose, metallic or other vessels capable of being hermetically sealed are sent out to the countries where the trees abound; these vessels being attached to the tree receive the juice through a connecting tube, as far as is practicable under exclusion from contact with the surrounding air. These vessels, when filled with juice, are hermetically closed by means of a screw-stopper or otherwise, and are then shipped to this country.

In effecting insulating coverings by means of these juices, which will be found to remain entirely liquid in the sealed vessels, the patentee proceeds in the following manner:—The naked wire or strand of wires is first covered with a layer of silk, cotton, or other fibrous material in the usual way; the wire thus covered is passed through or soaked in a bath of the juice, and drawn up through an air flue or shaft of considerable height, which is maintained at a temperature of from 100 deg. to 300 deg. Fahr., either by the external application of heat, or by a continuous supply of heated air from a stove. An arrangement for this purpose is shown at figs. 1 to 3 on the accompanying drawing.

Fig. 1 shows a transverse section of the same on line X, X, fig. 2; fig. 2 shows a longitudinal section on line Y,Y, fig. 1; fig. 3 shows a sectional plan on line Z, Z, fig. 2. The same letters of reference indicate the same parts in each of the figures.

A is a broad brick shaft with the hot-air flues B, B_1, on each side; C, C_1, are two stoves for heating the same; a series of pulleys D is placed on an axle at the top of the shaft, and a second series D^1 is so arranged at the bottom that the pulleys can be submerged in a bath E, containing the juice of the india-rubber or gutta-percha tree, or each pulley may be placed in a separate bath. The wire is led into the shaft over the guide pulley *d*, and dips immediately into the bath E, by which it becomes covered with juice; it then rises up the shaft A, where, under the influence of the heated air, the film of juice adhering to the covering of the wire on leaving the bath becomes rapidly consolidated and dry. The wire is passed over one of the top pulleys and down again into the bath, by which it receives a second film of juice, which dries in the same way, as the wire again passes up the shaft, and so on, till the wire has got a sufficient number of coatings, when it passes away over the pulley d^1. Instead of one large bath of india-rubber juice or gutta-percha juice alone, these two substances may be mixed with advantage, or a number of small baths containing alternately gutta-percha and india rubber juice may be substituted, so that the wire would receive alternate coatings of these substances.

In suspending telegraph line wires in the air, an insulator is employed, consisting of an inverted bell of porcelain or hardened india rubber or ebonite, which is cemented into an inverted cup of cast iron to protect the same from rain and injury, which cup may be either painted, galvanized, or enamelled. A iron or steel stalk, the surface of which is either enamelled or covered with ebonite or hornified india rubber as far as it will be exposed to the atmosphere, is cemented into the inverted insulating cup and turned up at the lower end, or provided with other means for supporting or fixing the line wire. The cast-iron protecting cup is furnished with an arm terminating in a socket, the axis of which is parallel to that of the cup, and which is slipped over the post or main support; or in place of a socket, a curved flange is formed at the end of the arm, fitting partly round the post, against which it is firmly secured by means of a horseshoe strap passing over it and through an iron saddle on the opposite side of the post, where it is screwed up, as shown in section and plan at figs. 10 and 11, where F is the inverted bell of porcelain or hardened india rubber; H, the inverted cup of cast iron; I, the enamelled stalk; J, the arm; J^1, the flange to the same; K, the strap; and L, the saddle-piece.

Two such insulators may be formed on the same bracket to support a wire on each side of the post, as is shown at M in figs. 4 to 7. In this case, either a set screw *m* or a wedge may be employed for fastening or steadying the bracket on the post. The posts mostly hitherto employed have been of wood, and iron structures with or without wooden tops have also frequently been used. The wooden posts do not afford a durable support to the insulated wire, as they are subject to decay; and the iron posts hitherto employed are very costly and difficult to transport. In order to meet these difficulties, the patentee constructs telegraph posts of three parts, to be carried separately and put together on the spot. The part of the post which is buried in the ground is formed of a dished plate of wrought iron, combining lightness with rigidity in a remarkable degree. A cast-iron pipe is fixed by bolts to this foot plate at or near the middle, which pipe rises considerably above the ground line and terminates in a socket to receive the upper portion of the post, which consists of a conical tube of wrought iron welded together longitudinally, combining strength with lightness and compactness in a high degree. This tube is fastened in the socket by pouring in a cement, consisting by preference of sulphur with an admixture of oxide of zinc or other metallic oxide. The wrought-iron tube may be surmounted by a metallic rod for the discharge of atmospheric electricity into the ground. Both the lightning discharger and the stalk of one or more insulators may be dropped side by side into the top of the wrought iron conical tube, and be secured by a wedge or in any other suitable manner. Each of the three essential parts composing this post is of such moderate size and weight as to admit of convenient transport, which is of great importance in constructing telegraph lines through uncultivated countries.

Figs. 4 and 5 show a sectional elevation and a plan of this construction of telegraph posts. N is the dished plate; O is the cast-iron socket attached thereto, and P is the conical wrought-iron tube; Q is the lightning conductor formed with a loop at the top, through which a wire passes connecting all the posts with each other, so as to discharge simultaneously through all the posts.

Figs. 6 and 7 show a sectional elevation and a plan of certain modifications, in which, instead of bolting a dished or buckled plate of wrought iron immediately to the foot of the tube, it is bolted to the flange of a cylindrical cast-iron socket R, into which is cemented the lower end of a cylindrical wrought-iron tube O^1. Inside the latter, near the upper end, is rivetted an inverted iron cup *o*. The upper tube is conical and of wrought

SPENCER'S STEAM-ENGINES.

FIG. 1. FIG. 2.

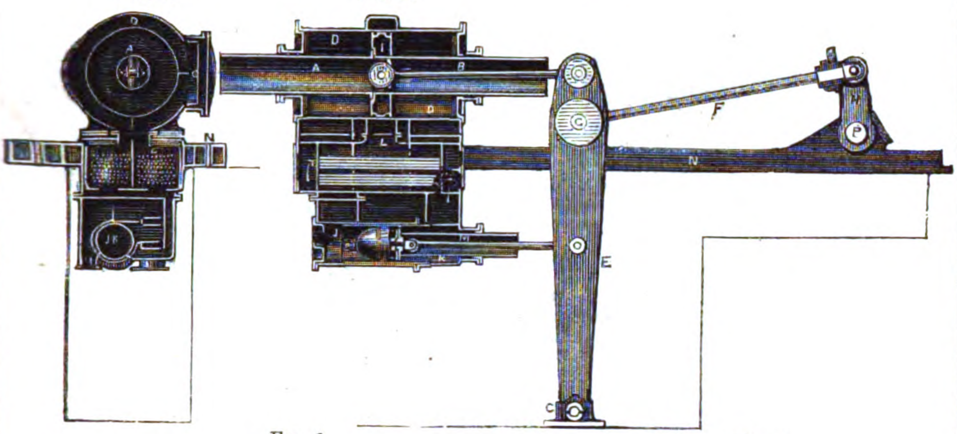


FIG. 3. FIG. 4.

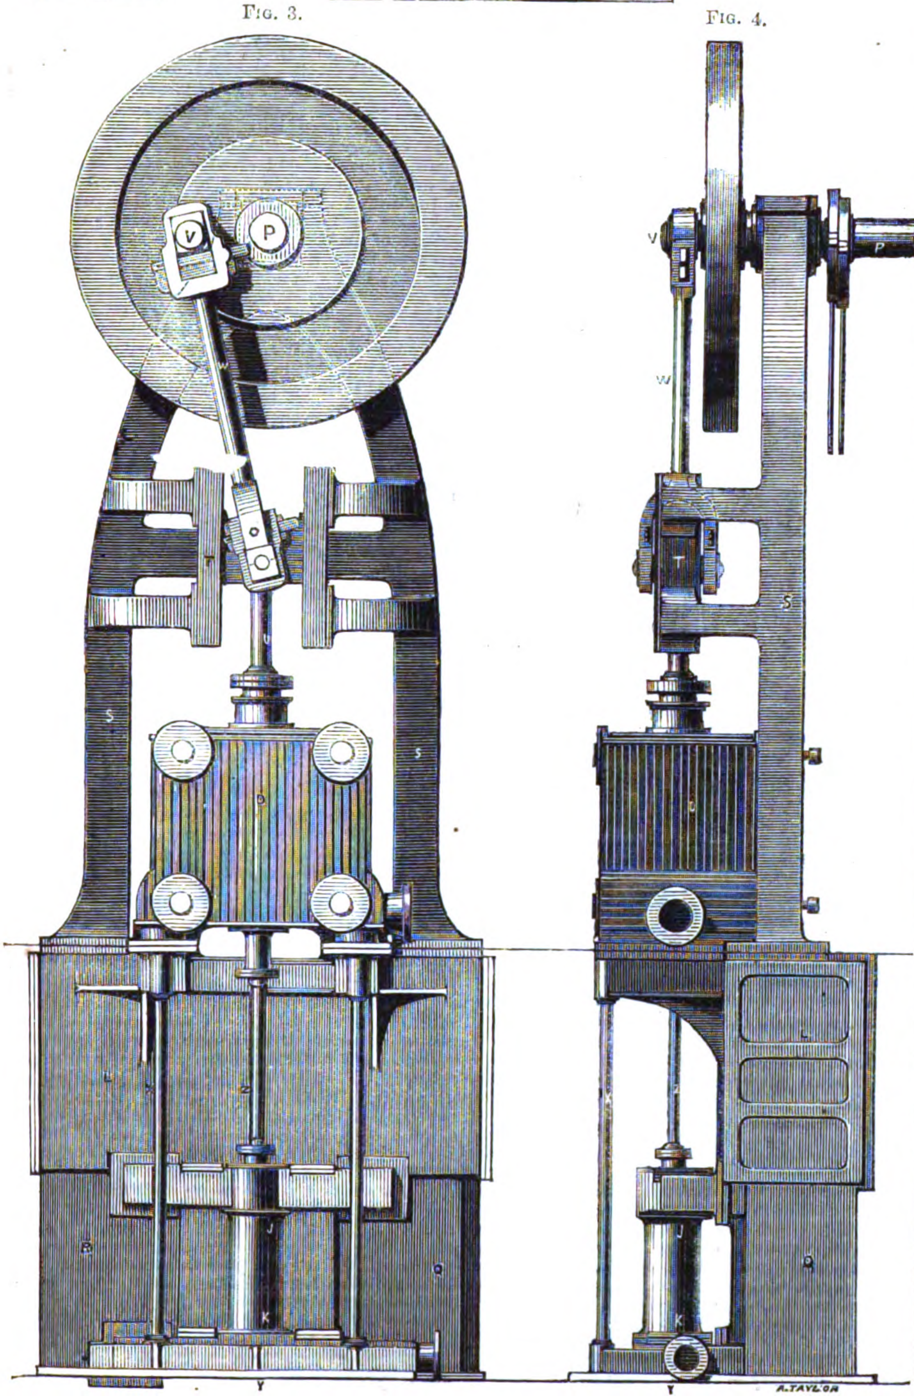

iron; its lower end rests on the bottom of the iron cup *o*. A cast-iron collar or boss *p* is passed over the upper or conical tube, and pressed down, by hammering or otherwise, until it rests on the top edge of the lower tube. The joint is then completed by pouring fluid cement through a hole in the collar.

A second modification, shown in part sectional elevation and plan at figs. 8 and 9, consists in connecting the tube O¹ to the foot plate N, by means of a cast-iron collar S bolted on to the latter, the bottom of the wrought-iron tube being hammered outwards so as to form a flange upon which the collar presses.

SPENCER'S IMPROVEMENTS IN STEAM-ENGINES.

THE following improvements in steam-engines have been recently patented by John Frederick Spencer, of Newcastle-on-Tyne.

This invention relates to improvements in arranging and combining together the parts of steam-engines with surface condensers to suit particular requirements and situations.

One modification of the improved arrangements, which have reference to the convenient working of the air and cold-water pumps, is suitable where the crank shaft is required to be near the ground line, and where space can be afforded for a horizontal or inclined engine or engines. This modification is represented, so far as is necessary for convenient explanation, in figs. 1 and 2 of the accompanying drawings, these two figures being vertical sections taken at right angles to each other. In this plan, a hollow piston rod or trunk A is used, having jointed inside it a short connecting rod B jointed at its other end to a vertical lever E, working on a fulcrum C some distance below the level of the steam cylinder D. The main or usual connecting rod F is jointed to the vertical lever E at a point G below the joint of the connecting rod B; it may, however, be jointed to the vertical lever E at any convenient point above, below, or in the line of the cylinder D, the throw of the crank H being correspondingly greater than, less than, or equal to the stroke of the piston I. The lever E may consist of a single arm or plate, or of two or more arms or plates having the joints between the plates. Separate pumps for the air and for the cold water may be used, but it is preferable to employ a combined air and cold-water pump J, K, as shown, when there is only one steam cylinder D, the pump being placed horizontally beneath the steam cylinder D and condenser L, and being worked from the lever E by a rod jointed inside of the hollow piston rod or trunk M of the pump piston; the feed pump may also be disposed horizontally in any convenient position, and be worked in a similar way from the lever E. The surface condenser L is placed immediately under, and forms the support of the cylinder D; and it may be cast in one piece with, or be united to, the frame pieces N, having at the opposite end the bearing or bearings for the crank shaft P. The condenser L, with the side frame pieces N, is firmly bedded on and bolted to masonry or timber foundations, as may be required, and the air and cold-water pump J, K, is bolted to the under side of the condenser L. The condenser L is represented as arranged internally, according to the usual system, the tubes being placed horizontally and parallel to the axis of the steam cylinder D. The inner end K of the pump acts on the cold water, forcing it into a lower compartment between the inner tube plate and cover of the condenser L, from which compartment the water passes through the lower half of the tubes to the other end, returning again to the inner end through the upper half of the tubes. The back or outer end J of the pump acts on the water of condensation and the air, these reaching it from the condenser L by passages, the arrangement of which will be easily understood from the drawings. With these arrangements, both ends of the condenser are conveniently accessible for examining the tubes and the various passages, and other details can be got at with facility. A surface condenser of

any suitable known kind may be substituted for the one described.

When two steam cylinders are used, each may be combined with a separate surface condenser similarly to the arrangement described, or a single surface condenser may be placed between the two cylinders, and at a level sufficiently low for the exhaust ports to drain into it, and in this case the condenser shell bedded on and bolted to masonry or timber foundations, forms the support of the cylinders inside, whilst outside they are supported by masonry or timber, as required. If three or more steam cylinders are used, either the arrangement last hereinbefore described can be extended, or each cylinder may be provided with a separate condenser. When two or more steam cylinders are used, the air and cold-water pump or pumps may be attached to the condenser side or sides.

Another modification is suitable where it is required to have the crank shaft some considerable height above the ground or floor level, and the modification is represented as applied in the case of a single steam cylinder in figs. 3 and 4. In this case, the condenser L is placed partly or entirely under the ground level, and is supported below on two hollow-chambered legs Q, R, cast on or bolted to it—one leg Q forming the hot well, and the other R an air vessel for the cold-water pump. On the top of the condenser L there are placed a vertical steam cylinder D, and an arched or two-legged standard S, the latter carrying one of the bearings for the crank shaft P, and, having attached to it the piston rod, guides T, the piston rod U, and crank pin V, being connected together by the common connecting rod W. The steam cylinder D considerably overhangs the condenser L, its outer side being supported by columns or standards X resting on a sole plate Y. Below and on this sole plate Y are fixed, vertically, either separate air and cold-water pumps, or, as is preferred and shown in the drawings, a combined air and cold-water pump J, K, which is worked directly from the main steam piston by a rod Z passed through a stuffing box in the bottom or lower cover of the steam cylinder D. The valve chambers and passages in connection with the pump J, K, are arranged conveniently for access, as will be clearly understood from the drawings. If two steam cylinders are used, the second cylinder with vertical pump below it may be similarly arranged at the other side of the condenser, additional standards being provided, as required.

LIGHTING OF COAL PITS.

A NEW method of illuminating fiery collieries has been proposed by MM. Dumas and Benoit, and which they say, so far as their experiments have gone, gives promise of success. In effect, the method consists in supplying each pitman with a "Geyseler Tube," in place of a Davy lamp. The light within the tube, which is of fluorescent (uranium) glass, is produced from a Rhumkorff's coil placed at a distance from the face of the workings. Insulated wires lead from this to each of the illuminated tubes, which can as easily be moved about as a Davy lamp, except, we may remark, that there will be always dangling from each the pair of wires; and as the tubes are hermetically sealed and do not rise perceptibly in temperature, or as the inventors express it, "*la lumiere est froide*," so there is no possibility of ignition for the explosive gases. The light obtained, they admit, is feeble, but this they expect to improve upon.

A ruptured wire might, we submit, produce ignition at the instant of fracture, in this case; otherwise the apparatus is probably perfectly safe. We doubt its likelihood of success in a practical sense however; although we feel perfectly certain that sooner or later all coal pits and all mines will be illuminated by some form or other of electric light; and that the Davy lamp, beautiful and ingenious as its principle is, and with all the good service it has done, will come, before very many years shall have passed, to be deemed a thing of a comparatively barbarous and imperfect epoch of mining.—*Practical Mechanic's Journal.*

TESTING ARMOUR PLATES.

THE recent firing at 5½-inch armour plates on the side of the "Monarch" target ship at Portsmouth was attended with an unusual degree of interest, owing to the fact of its being the first time the four leading firms in England had supplied plates of equal thickness of metal for trial. We learn, from the *Times'* report, that they consisted of one each from Messrs. John Brown and Co., of Sheffield, the Mersey Iron and Steel Works, the Thames Iron Works and Shipbuilding Company, and the Millwall Company. All four were good plates, but with varying degrees of excellence. Messrs. John Brown and Co's. plate is the best of the four. Four shots struck this plate in a vertical line, but they opened no cracks in the same direction, nor otherwise, except in the indents. Two of these shots overlapped each other 3 in., but the result of the two blows only produced an indent of 2½ in. in depth—an unprecedently favourable result, as showing the excellent resisting power of the iron. Eight shots struck within 3 ft. of the left of the plate, and three of them on the very edge, but only produced the usual small cracks exhibited by this firm's plates within the circumference of the indents. No signs of concentric cracks are shown round the indentations of these edge blows. The Mersey plate received 13 shots in all, and stood very well for the "first" rolled plate produced by this firm. The metal has a soft appearance, and seemed of good quality; but there was a tendency in it to crack vertically—a fault which will, doubtless, be guarded against in future productions. The Millwall plate was not of so good a quality as the 5½-inch plates previously sent in for trial by the firm. The welding was very faulty. It received 11 shots. The Thames Company's plate was very severely injured by the 9 shots fired against it striking on the weakest points. Five struck in an area of 3 ft. by 18 in., and three of them joining in their circumference of indents. The effect, however, was only slight, though numerous cracks were made from the severe pounding the iron had received. The gun used was the ordinary 68-pounder, and cast-iron shot with 16 lbs. of powder, at 200 yards' range. On the day following the trial of the plates, a smooth-bore 100-pounder gun was shipped from the "Excellent" on board the "Foam" gunboat, and the latter vessel proceeded up the harbour, and took up a 200-yards' position from the target ship and the plates she had fired at with her 68-pounder on the previous day. A shot was fired at each plate with a 25 lb. charge of powder, and in all but one instance the damage inflicted appeared to be commensurate with the increased weight of the shot and size of the charges, as compared with the 68-pounder. A further careful inspection hardly confirms this belief. In all but one instance the plates had been damaged by previous firing from the 68-pounder, and no fair inference could therefore be drawn from the results. In the one instance referred to the Millwall plate was struck fairly in an uninjured part by the round 100-pound shot, and the result was—diameter of indent, 10 in.; depth of indent, 3 in. There were cracks across the centre of the indent. The average diameter of the indent from the blows of a 68-pounder is 9 in., with a depth of 2½ in. The "Monarch" is now having plates bolted on her sides for further experimental firing, including a trial plate for the "Research" from the Butterly Company, and one from the Thames Company for the "Minotaur."

NEW WORKS, RIVER WEAR.

AT the meeting on Wednesday week of the River Wear Commission at Newcastle-upon-Tyne, a report was read from the Executive Committee upon the proposed new works at the River Wear. The report recommended that the length of the new dock should be 420 ft., but that at present it should be made only 250 ft. long, and 60 ft. broad at the entrance, so as to allow overlapping of vessels. The site of the new dock was at the south-east corner of the north half-tide basin, and beyond the length of 420 ft., it would be necessary to construct a barrier to the sea. The next subject was that of reconstructing the north-east pier of the south harbour or outlet, on plans by Mr. Meik, with a view to give the outlet additional security. It would be a perfectly independent pier—independent of the present groyne pier, could be constructed with great ease, and completed for £13,000. Mr. Meik, the engineer, reported with respect to the outlet, that the new breakwater forming the west pier of the new harbour was close upon completion, and he anticipated from it most beneficial results to the scour of the channel and the protection of the dock gates, when the masonry of the breakwater was raised to its full height. It would give protection from the south easterly gales, while the proposed new north east pier would protect the harbour from north easterly gales. The effect of the new breakwater on the channel had been to increase the depth from 4½ ft. low water of ordinary spring tides, to an average of 9 ft.; and as the foundations of the pier gradually grew towards completion, it was observed that a little soft mud only, instead of sand, was deposited. He anticipated that now the scour would keep the channel quite clear, and the breakwater would act in stilling the waves, while the north east pier would protect the dock works. With respect to the graving dock, if they made it 250 ft. long at first, they could deposit the matter excavated seaward, which would form firm consolidated ground by the time they required the further extension of 420 ft. The work, if completed all at once, might be affected by the water. The plan has been approved, and the work will be proceeded with immediately,

THE BOLTS IN THE MONITOR TURRETS.

A PARAGRAPH in the *Scientific American*, called attention to the defective manner of fastening the plates in the monitor turrets, and suggested the hope that inventors would turn their attention to remedying the evil. In response to this call we have, says that paper, received many letters from different persons, all mentioning plans for preventing loss of life from the cause alluded to. Among some of these are the following:—The turret should be constructed of wire netting in several thicknesses, in all 8 in., or more, the whole to be well saturated with coal tar. It will be perceived that here bolts are needless, a most summary method of avoiding the trouble. Another plan suggested is to construct the bolts of a tapering form that they cannot be forced in by the shot; still another inventor says that by tapping the holes in the turret and screwing the bolts into them the danger will be obviated. A plan is also forwarded to us wherein india-rubber washers are placed under the bolt heads and iron shields over the nuts inside, said shields being secured to the turret body by tap bolts.

A correspondent, A. H. Fleury, of Philadelphia, directs our attention to a patent recently granted to Gervase B. Maurey, of Danville, Pa., for an improved plan of building up turrets, to avoid danger from the flying bolts, &c. The turrets are to consist of tongued and grooved bars, rivetted together in the centre, or inside of each bar, in such a manner as to make a continuous joining of all bars used in the work; they are laid lengthwise, or horizontally, and, as a consequence, present a smooth solid surface externally. The rivets running through them, perpendicularly, are placed 3in., more or less, according to the thickness of walls, from the surface. There can be no exposure of the rivets to shot or other projectile striking the side or surface of the vessel or fortification constructed of such bars. Mr. J. L. Jürgens proposes to build a turret of three different layers—one of wood and two of iron bars, standing in a vertical position, with cotton, india-rubber, or other elastic material interposed. The inner (wooden) strata to be stationary, the yielding to be increased outward, and the curved gullies in the cap and step, for said bars, to be increased proportionally, according to the yielding of the elastic material.

NOVEL CONVERTING PROCESS.

WE learn upon excellent authority (says the *Colliery Guardian*) that there is now being completed at Smethwick, near to Birmingham, an invention, which it is promised will be productive of the most important results in the manufacture of finished iron and steel. The statement is that some gentlemen, natives of Holland, have for a considerable period been occupied in perfecting machinery for converting molten iron into steel, somewhat after the method adopted by Mr. Bessemer, but it is alleged a greatly superior one. Some £3,000 or £4,000 is asserted to have been spent upon machinery and experiments by the inventors; and although all is not yet quite complete, still operations have so far progressed, that a company, it is understood, is about to be formed to bring the invention before the world. So far as the process is at present known, it is said to be carried on by the aid of machinery, the leading features of which are three vessels. In the first a description of gas is generated, the properties of which are known only to the inventors. This is passed into the second, which is a kind of crucible, and hermetically sealed. This crucible

has by that time been filled with pulverised cast iron, which is heated to a low temperature, at which certain vapours are given off that are taken up by the gas from the first vessel. Each has an affinity for the other, and both then pass in one stream from the bottom of the crucible, and it is conveyed into the third vessel, in which there is iron in a molten state. Here the effect of the combined gas upon the molten metal is such that in a brief time, and with scarcely any waste, the whole is converted into a very excellent quality of steel. Then, the powdered cast iron in the second crucible, after it has been used for the purpose named, is said to contain such intensely combustible properties that 1½ lbs. of it will give off as much heat as a ton of coal! further, the same material if introduced into the ordinary puddling furnace will, it is averred, so greatly facilitate the operation of puddling, that two tons of iron may, by its use, be made in the time now consumed in making one ton.

This is effected by the influence which the material exercises in hastening the "boiling" and in bringing to the surface the whole of the molten contents of the furnace, so that the carbon which is given off in the operation of puddling, may be taken up by the oxygen of the atmospere—a result the securing of which is the chief work of the puddlers. It require no remarks from us to convince every one that the invention, if only the half that is said of it be true, is one of the greatest importance, not alone to the makers of iron and steel, but to every consumer of those metals—and who is not a consumer?

HOW TO FORETELL THE DIRECTION OF THE WIND.

It is one of the general rules concerning the force and direction of the wind, that the wind will always be in an easterly direction when localities situated to the northward of some place of observation have a high reading of the barometer; and, on the contrary, the wind will be in a westerly direction when the reading of the barometer is higher in localities situated to the southward of the same place of observation. In the first instance, the wind, without exception, is between south-east and east-north-east, whereas the westerly direction is again almost without exception between south-west and north-west. If it so happens that at the same time there is a difference of the reading of the barometer between localities situated in an easterly and westerly direction from each other, the wind in the first case will partake more of the northerly, in the other case more of the southerly direction. The future direction of wind, therefore, may be determined by the following rule:—When one has the lowest reading of the barometer to one's left hand, the back is turned to the region whence the wind will blow. As for hurricanes, one has always towards one's left hand that locality where the wind will blow most vehemently; regard being, however, taken to the direction of the wind. The reading of the barometer in places towards the south from us is on the average higher, since westerly winds predominate; but as westerly winds are on an average more violent than easterly, one may pretty safely infer that an ordinary difference north above south is less to be apprehended than an equally large difference of south above north. When the barometer reads higher in the north than in the south, the force of the wind is certainly as much greater as the difference of the readings of the barometer is greater; it may even be as large as six millimetres, without there being any just apprehension of a gale of wind. The greater the difference, the more sure one may be that the wind will turn towards the east, and keep to that quarter for some days. It only occurs once in a hundred times that during the blowing of a westerly wind the barometer reads a couple of millimetres higher in the more northerly places; such occurrence invariably indicates a great disturbance of the atmospheric equilibrium; and a heavy fall of the barometer in the north, or a rise in the south, commonly even ensues the very same day; while even on that day, or a day or so later, a gale of wind from the westward begins to blow. When, on the contrary, the south reads four or more millimetres above the north, one ought to be on one's guard. If the reading of the north is above that of the south, and an easterly wind does not then quickly succeed, that rise of the barometer must not be considered as being due to a regular division of pressure of the atmosphere, but only to the temporary abiding of an atmospheric wave, and a strong westerly wind may be expected next day. According to accurate observations, we find that 40 times in 118 a gale of wind will ensue when the south reads higher, and I repeat, therefore, here what was already observed before—a gale of wind is always announced, but with the announcement the gale does not always follow. A danger known before it is really present ceases to be so, or at least loses a good deal of its power; and whether the gale does occur or not, one has been warned, and can be guarded. Science incessantly proceeds, and the day is not, perhaps, very far distant when in this department also very important truths will be brought to light. I ought not to neglect to observe that the gale does not always break out within the first twenty-four hours; the difference in the readings of the barometers is often again the same on the next and even on the third day; but the wind becomes heavier and heavier, and at last a violent gale breaks out. A ship, therefore, having left port on the first day, would not have fallen in with the gale of wind on that day, but only on the next ensuing. The repeated warnings are to be considered as *one*, which renders the whole more important.—*Chemical News.*

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post-office orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

RECEIVED.—A. J.—G. S.—J. N.—W. R.—S. S.—J. K.—G. W.—J. W.

N. M.—The examination is not very severe; specimens of your abilities as a draughtsman will of course be required. A moderate knowledge of engineering, the principles of construction, mathematics, and arithmetic, are indispensable. You will need some interest.

SAFETY.—The application of electricity to signalling on railways is by no means new, and we have failed to discover anything very original in your design. The simple cord as used on the Great Eastern and some other lines supplies every requirement.

P. T. (Bradford).—If the load is quiescent, a 1-in. rod is sufficient to sustain 5 tons.

Z. Y. (Newcastle).—Your injector has failed simply because the tank is too far below it. With such small instruments as those numbered 3 and 4, the tank should always be placed a foot or so above the injector.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

BOILER EXPLOSIONS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Mr. Colburn having failed, in his note last week, to deal with my letter of a fortnight ago, except in one point, allow me to reply that the discussion on the explosion on board the "Great Eastern" took place on Monday or Tuesday, the 12th or 13th September, 1859, which was *before* the publication of the first article on that subject in the *Engineer* of the 16th following; and not *after*, as he, for the first time, suggests; whereas, in the whole course of his correspondence with me, until now, he has never questioned the actual sequence of events, though they have been occasionally adverted to and recognized therein.

My explanation of the phenomena of the explosion, *then*, was the same as it is *now*, the same as I have frequently made in that correspondence, and the same as I made in the *Encyclopædia Britannica*. He alleges that he did not understand it, that he now understands it, and that he dissents from it; nevertheless, it affords, I believe, a plain and instructive illustration of my projectile theory.

That he either did not understand my explanation, or dissented from it at the time, is proved by his first leader on the subject in the *Engineer* of the 16th September, 1859. "The casing," he then said, "must, up to the moment of collapse, have been full of water." "The first incident of failure having been a collapse [in which he agreed with me], and as soon as the pressure upon the 11 tons of water was removed, this was, to a great extent, instantaneously converted into steam, and, with an energy sufficient to complete the catastrophe, by exploding the outer casing." And, in the *Engineer* of September 23, 1859, he adds, "The contained heat of the water would instantaneously convert a considerable portion, *if not all of it*, into steam, and with such suddenness as immediately to render apart the outer casing"!! Note—first scientific blunder—*all* the heated water "flashed into steam," 11 tons of it; whereas only 154 lbs. weight, or 1-160th part of it could have "flashed" into steam before the explosion; second—not the slightest allusion to percussive action.

At last, in the *Engineer*, of October 21, 1859, he says, "The percussion [first time he used the word, after discussions with me] of this steam upon the plates would, in all probability, be quite sufficient to have broken them." Note—this is very like a part of my original explanation.

But he changes his ground, in the *Engineer* of April 19, 1861, and explains the explosion—first, by the occurrence of a *local rupture above* the water-line [how could that be if the casing had been *full* of water?]; second, the instantaneous escape of steam from *over* the water; third—the disengagement of steam from the heated water and the percussive action of the steam against the upper surface of the boiler, which might thus be rent violently open. "The obvious fact," he adds, "that the steam, in its rapid disengagement, must carry water with it, was not then dwelt upon." Observe how entirely different his first and second explanations are to each other. Instead of *collapse*, the first incident is rupture; and again, he accepts the fact that the water was not all evaporated, and that it was carried by and projected with the steam.

If then, Mr. Colburn does really dissent from my explanation of the explosion, I am curious to learn in what respects he dissents.

As I have already stated, he has not attempted to deal with my last letter. It would be easy for me to prove, from his writings and his correspondence with me, his self-contradictions, and his want of originality in this matter; a precedent can be found for everything that he claims as new. But I scarcely think it is necessary to do so at present, or so long as the points raised in my last letter remain unanswered. He has, as I have said, repeatedly declined a friendly reference to third parties, which would be better than a cumbrous process of weekly correspondence.

With respect to your appended remarks upon my last letter, I may observe that I thought the editorial function applied to tangible evidence in whatever form it might be offered; and I may add that, whatever may be the value of Mr. Harshman's theory, Mr. Colburn is indebted to Mr. Harshman for the substance of the first proposition in his enunciation of my projectile theory—that is, the first in what he calls "the series of consecutive operations" resulting in a boiler explosion—namely, "1. The rupture, under hardly, if any more than, the ordinary working pressure of a defective portion of the shell of the boiler; a portion not much, if at all, below the water-line."

I am, Sir, your obedient servant,
D. K. CLARK.

11, Adam-street, Adelphi, W.C.
October 6, 1863.

IRON WALLS AND THEIR ARMAMENT.

SIR,—I have read with interest the Papers on field and heavy ordnance, which in the course of the last few weeks have appeared in your journal. The writer has analyzed and epitomized with much care and intelligence the information on guns and projectiles which he has culled from authentic sources. These labours are valuable to the general public, who take an interest in those matters, but have not time or opportunity to have recourse to original channels.

The facts and theories promulgated, however, acquire their chief value from the aptness and truth of the deductions drawn from them. The object of scientific discussion on practical me-

chanics is to dispel ignorance and error, and open the way for inventive genius.

Availing myself of your liberality to correspondents, I beg to offer some observations on the great national question treated upon in the articles referred to.

The writer divides his subject into two parts—1. For land service, "rifled field-pieces of long range and extreme accuracy." 2. For sea service, "heavy guns, combining smashing effect and penetrative power at considerable range, without great pretensions to accuracy." In the latter class, no doubt siege guns, although for land service, are intended to be included.

This division is correct and intelligible; the two branches of the artillery question have been skilfully handled in your columns. On the first I do not propose to make any remark, except to express a wish that the construction of the American field-pieces, which have committed "such tremendous havoc" in the ranks of the opposing armies, were more accurately described than by the statement that "American parks of artillery are usually distinguished by the presence of numerous guns sufficiently like those of Whitworth and Armstrong to be regarded as nearly identical." An impression prevails in this country that Whitworths and Armstrongs differ materially in the qualities essential to a good field-gun. I will not stop now to go into that vexed question, which the Special Competitive Committee seem by some occult influences to be deterred from entering upon. It may, however, be interesting to your readers to be reminded, by the following abstract of the report of the Ordnance Select Committee, of the results obtained in a competitive trial, to "ascertain range and deflection in comparison of Whitworth's B. L. 12-pounder with Armstrong's B. L. 12-pounder gun":—

Armstrong's Gun.

Charge. lbs.	Elevation. deg.	Range. yds.	Deflection. yds.
1·50	2	1,130	4
1·75	,,	1,256	5
1·50	5	2,146	9
1·75	,,	2,358	11
1·50	10	3,568	12
1·75	,,	3,908	17

Whitworth's Gun.

Charge. lbs.	Elevation. deg.	Range. yds.	Deflection. yds.
1·50	2	1,198	$1\frac{1}{3}$
1·75	,,	1,289	$1\frac{2}{3}$
1·50	5	2,367	$1\frac{1}{3}$
1·75	,,	2,471	$1\frac{2}{3}$
1·50	10	4,222	3
1·75	,,	4,399	$6\frac{2}{3}$

The victory remained to the Whitworth, and yet, although more than two years have elapsed since those experiments took place, the Armstrongs have been and are the preferred service guns of the British artillery. So much for the justice of the Ordnance Department, which of two systems of field-guns selects the least effective for the public service. It is very desirable that data as to the character of the American field-pieces similar to those in the above reports should be published in your pages. We could then judge if the "tremendous execution and long ranges" of those guns could not be equalled by field-pieces manufactured in this country.

Coming now to naval ordnance, I see that a distinction is drawn between smooth-bore and rifled guns. The gist of the argument is that heavy cannon—150 and 200-pounders—cannot be produced in the rifled form without danger of their bursting, unless "the American plan, which is very different from ours," be followed. The American plan here referred to is afterwards stated to be the well-known Parrot gun, of which an accurate and interesting account is given in the Mechanics' Magazine of the 25th September. This cannon is described as rifled with shallow grooves and lands, each an inch in width, and having a slow twist; and the shot as a conical projectile, with rather a sharp head, and a soft brass ring cast into its breech-end. "The explosion of the shot upsets the brass ring into the shallow grooves, imparting rotary motion to the shot." We are told that "little is known in this country of the Parrot gun, and that it is beyond dispute the best in the American navy."

For the credit of British artillerists, I am happy to state that we possess a gun of precisely the same character as the Parrott, and that gun is Mr. Bashley Britten's. Without endorsing the opinion that it is the best naval piece of ordnance that can be produced, I admit it to possess great merit; and I have no doubt it would be more serviceable and more effective in every respect than the Armstrong. Like the Parrott, it is a muzzle-loader, is rifled with shallow grooves and lands, each about an inch wide; it also has a slow twist, and is fired with a charge of 1-10th the weight of the shot. The mode of stopping windage and causing rotation of the shot is in principle precisely similar—the only difference being that the soft metal cast into the breech-end is a disc of lead instead of a ring of brass. This plan is known as the "expansion system," and is among the best; superior, I think, to the Wahrendorff or compression system, which is often erroneously spoken of as Sir William Armstrong's invention. "Honour to whom honour is due." I present to your readers an abstract of a report, showing the results of a comparative trial of a 50-pounder Britten *versus* a 40-pounder Armstrong. The object was to determine "the effects of equal charges in large and small bores." In the report the following particulars are recorded:—The Britten was a rifled 32-pounder cast-iron service gun; the bore 6·375 in., the weight of the shot 50 lbs., and of the charge 5 lbs., or 1-10th; initial velocity 1,209·2; pressure on shot 415 tons, and on sides of gun 1,204 tons. The Armstrong was a rifled breech-loader, the bore 4 in., the weight of the shot 40 lbs., and of the charge 5 lb., or ⅛th; initial velocity, 1,200; pressure on shot 163 tons, and on the gun 1,964 tons.

Here, again, the Britten bore away the prize, the Armstrong lagging behind. Nevertheless, the latter are introduced in the service; and Mr. Britten, having proposed his system to the War-office for heavy broadside guns, is still waiting, as he has been for months, whilst "the question is under consideration." At a scientific meeting, Mr. Britten, plaintively but naturally, said "he thought it only fair that he should be allowed to compete with Sir William Armstrong on equal terms." Your readers, no doubt, will unanimously be of the same opinion.

Not wishing to trespass too much on your well-filled pages, I will close this letter; and if you will allow me space, I will conclude what I have to say on naval guns in another letter.

Civilian.

THE "GREAT EASTERN."

Sir,—The experience gained in the career of the "Great Eastern," renders it but too obvious that important changes are necessary to give her ordinary seaworthy and manageable quantities before she can be again started agoing. She must be cured of her rolling propensities. Bilge logs might partially check this, but would not remove the evil. What is wanted is a certain lifting power below the water line at each side, and under or outside the main breadth. It would require (judging from her model) 1,200 to 1,500 tons' displacement at each side to furnish sufficient upward force at this point to effectually do away with her liability to roll and bear her up under a press of canvas. The paddles may then be taken away and a portion of the boilers and machinery, &c., and in addition to the present screw, we would introduce two other screws, somewhat less, one under each quarter—the latter to assist in steering, and also propelling. We would then have three submerged propellers, or screws, at the stern, where they ought to be, and without canvas would doubtless make the ship go, and keep her under control. 40 to 50 ft. sliced off the thin part of her forefoot would also be a good thing. Three funnels would be plenty—two only, better. I would alter the rig by doing away with all square sails and adopting staysails and trapezium sails, say, five most in all—foremast, second foremast, main-mast, mizen-mast, and jigger mast. She may then be sent to any part of the world, and it is more than probable that she will answer and prove a success—a thing very desirable.—I am, &c.,

John Kennedy.

Whitehaven, Oct. 6, 1863.

J. GRANTHAM'S HYDRAULIC PRESSES.

Sir,—In the Mechanics' Magazine of September 2, you published an illustrated description of J. Grantham's Improvements in "Hydraulic Presses," patented on the 19th February, No. 391. I trust that, as an act of justice more than as a favour, you will allow me to refer your readers to an illustrated description of similar or rather identical improvements, which appeared in your valuable paper of the 28th August last, and which improvements were patented by Mr. Robert Lüthy on the 10th of January last, No. 87.

I enclose my card, and remain, Sir,
Your obedient Servant,
C. E. R.

London, Oct. 7th, 1863.

Miscellanea.

The Italian Government have contracted with Mr. W. T. Henley for the manufacture and laying of a submarine cable 62 miles in length, from Otranto to Avlona, which will give a route by way of Italy for messages to Constantinople, and thence to the new line *via* the Persian Gulf to India.

Four of the large iron cylinders cast at the foundry of Messrs. Aveling and Porter, Rochester, have been received at Chatham dockyard, to be used in the works now in progress for the enlargement and extension of that establishment by taking in the whold of St. Mary's Island. The cylinders, which are the largest of the kind ever manufactured for that particular operation, are intended to be used in the construcrion of the new basins and docks, the foundations for which are now being excavated. In the construction of the new basins and docks advantage has been taken of St. Mary's Creek, which intersects the southern portion of the island, and the bed of the creek, which is now being drained, will, in fact, form the site of the three basins, the united area of which will be nearly 90 acres, or about double the extent of the whole of the existing available basin accommodation at all the Royal dockyards. Up to the present time the entire work in connection with the enlargement of Chatham dockyard has been performed by convicts, of whom between 800 and 900 are daily employed.

On the 1st day of this month the new time-gun for Glasgow was fired for the first time at 1 o'clock, simultaneously with the discharge of the pieces at Edinburgh, Newcastle, North Shields, and Sunderland. The experiment was witnessed by a large number of spectators; and some interest has been awakened as to whether it may be established as a permanent regulator of city time. Until the matter is definitely decided, the gun will be fired every day at the same hour. The attention which has been called to the subject by this time-gun experiment has led to another scheme being proposed with the same end in view. Steps are now being taken to connect by an electric wire the Glasgow Observatory with one of the turret clocks in the city, for the purpose of controlling the latter by the normal clock of the Observatory, as practised so successfully at Liverpool. The controlling of a seconds clock by the same method (Jones's) is also under consideration.

The President and Government of the Peruvian Republic have for some time past been engaged in the most active measures to develop the resources of that country, and especially to open up the river Amazon, and its numerous large branches in the interior, to European commerce and enterprise. For this purpose several small screw steam-vessels have been constructed at the premises of Messrs. Samuda, and other firms on the Thames, which have already been forwarded to their destination; and a squadron, consisting of the "Arica," the "Eliza," and another steam-vessel, are about to sail, taking out an immense iron floating-dock, steam-engines, planing and drilling machines, steam-hammers, and the entire details of an engineering plant for the establishment of a factory, to make and repair every kind of machinery used for the cultivation and preparation of cotton, tobacco, rice, sugar, &c. The whole arrangements are under the superintendence of Mr. Clark, chief engineer, who will sail with the expedition, and will take out with him a considerable number of

skilled engineers, smiths, and other mechanics, who have been engaged at a liberal rate of wages by the Peruvian Government, which will also grant a free passage for the families of married men. During the past two years several young Peruvians, sent over by the Government for that purpose, have been learning the profession of engineering at the premises of Messrs. John Penn and Son, Greenwich. The importance of improving that immense territory, east of the Andes, was first recognized and acted upon by the late President of Peru—General Castilla—whose enlightened views are fully endorsed by the President now in office.

Spiegel Eisen is getting much into use at Sheffield, in the Bessemer process (as a carbonizer), and also for making steel, the charcoal quality suiting very well for this purpose, on account of the large proportion of manganese and carbon it contains. The Government are now experimenting on this class of iron at Woolwich (with the intention, it is understood, of using it, like Krupp of Essen, in the manufacture of steel cannon). For rolled armour-plates it is also likely to come much into use, being used in a process which we are at present not at liberty to name. There are various sorts of spiegel iron, but the charcoal-made quality is considered to be the best suited for the purposes named.

The *Mining Journal* states that a very compact and efficient form of blast-engine is at present being manufactured by Messrs. Wm. Coulthard and Sons, of the Park Ironworks, Blackburn; the chief feature, however, is the substitution of the india-rubber ball valves for those usually employed. The engines are described as applicable to blast-furnaces, foundries, &c., and may be constructed for any pressure of blast from 3 lbs. to 30 lbs. on the square inch. The ordinary cost for foundation is avoided, and the machine occupies a very inconsiderable amount of space.

From the quarterly return of vessels in course of construction at Sunderland, it appears that there are a total of 101 vessels now on the stocks, 47 of them being sold, and 54 remaining unsold. 17 are of iron, 3 of wood and iron, and the remainder wood vessels. Two of the iron vessels are screw steamers—one of 690 tons, building by Mr. Laing; and the other 790 tons, by Messrs. Pile, Hay, and Co. Mr. Laing is building an iron ship of 1,320 tons register; Messrs. Pile and Co., two iron ships of 1,050 and 1,033 tons respectively; Mr. Smurthwaite, a wood ship of 1,150 tons; and Mr. John Watson, a wood ship of the same dimensions. The aggregate tonnage of the 101 vessels amounts to 43,976, an average of 435 tons each.

A large and powerful engine has just been made by Mr. Andrew Barclay, Caledonian Foundry, for Messrs. Robb, Greig and Co., carriers, and is intended to run on the road between Glasgow and Kilmarnock. It was taken out on trial on Friday afternoon, and, followed by a large number of persons, made a circuit from Mr. Barclay's works up the front streets of the town. In returning it had to run up Langland's Brae, and this it did in a very satisfactory manner. The machinery for turning corners resembles outwardly the means used for steering a ship. The engineer turns a wheel with handles, to the axle of which is placed an endless screw, which communicates motion to the shafts underneath.

Telegraphic despatches of twenty words are now forwarded in Prussia up to a distance of forty-five miles for 9d.; for any distance between forty-five and 200 miles similar despatches cost only 1s.

Advices from Lyons state that a process is talked of by which silk can be liquified, and the produce of the worms kept in casks for artificial re-issue in filaments susceptible of quite a novel form of manipulation. It would appear that what is meant bears some affinity to the treatment and uses of gutta percha. It is already known that surgical science has turned to account for ligatures of human arteries, the yet unspun contents of the worm or caterpillar before it enters the cocoon.

Mr. John Key, of the Whitebank Engine Works, has laid down the keel of a large iron vessel at his ship-building yard near Kinghorn, at present in course of completion. It is to be an iron screw-steamer of 800 tons, constructed to carry 220 first and second-class passengers, and fitted up with engines of 160-horse power. Three orders have already been received for iron vessels for the passenger trade—one from a London and two from an Australian firm; and the keel of one of the Australian vessels has been laid. The new yard, which is about 400 ft. long by 250 ft. broad, is situated on a partly natural and partly constructed slope, admirably suited for the purpose, and will give accommodation for four iron vessels of 1,000 tons each. At the head of the slip are the workshops, which consist of a double building, one side of which is a single storey for the blacksmiths' shop, 220 ft. by 38 ft.; and the other side is in two storeys, 220 ft. long by 40 ft., for a moulding loft and machine shed. This new branch of industry, which to all appearance will be carried on on an extensive scale, will be of great advantage to the town of Kinghorn. We understand that steps have already been taken to form a building society to accommodate the workmen with suitable houses.

We are requested to state that as the Fenton Memorial Fund is not yet closed, Mr. Joseph Freeman will take an opportunity of communicating the result to those who have so kindly contributed.

An eminent Parsee merchant firm in the city of London has presented £2,000 to the Royal National Lifeboat Institution, through its chairman, Thomas Baring, Esq., M.P., to enable it to form a lifeboat establishment on the English coast, and permanently to keep it up. Their firm is now under dissolution; and in order to show their gratitude to the people of the great metropolis, from whom they have received for many years every courtesy, they have presented this munificent amount to this benevolent institution.

An iron-clad frigate, built for the Italian Government, has just been launched from the building-yard at La Seyne, near Toulon. She is of 4,300 tons measurement, has engines of 700-horse power, and is to carry 36 guns. She takes the name of "San Martino." Her bow below the water-mark is formed so as to act as a steam ram. She is everywhere covered with thick plates; but those towards the bow, which would be the most exposed to the force of any shock, are much heavier than the others.

The report of Mr. Joseph Dickinson, on the inspection of mines in the North and East Lancashire or Manchester district for the year 1862 has been issued. He states that the explosions of fire-damp, although fewer than last year, and unattended with large loss of life, were too numerous to be creditable to the management. Accidents occurred which might have been prevented if some person of experience was appointed to manage the collieries. The decrease compared with the preceding year was 11 accidents and 23 deaths, and the total number of accidents during the year was 56 and the number of deaths 59. The accidents were classified as follows:—Firedamp, 9; fall of coal, 6; fall of roof, 14; breaking of rope and chain, 1; whilst ascending or descending, 7; falling from part way down, 4; miscellaneous, 1; explosion of powder, 1; on incline planes, 3; by trams, 2; underground, 1; boilers bursting, 2; miscellaneous on surface, 5; total, 56. The deaths were, from firedamp, 10; fall of coal, 7; fall of roof, 14; breaking of rope, 2; while ascending and decending, 7; falling from part way down, 4; miscellaneous, 1; explosion of powder, 1; on inclined planes, 3; by trams, 2; underground, 1; boilers bursting, 2; miscellaneous on surface, 5; total, 59. There had been 30 non-fatal explosions of firedamp, and 27 non-fatal explosions of blasts and blasting powder. The causes of accident principally arose from there being no viewer or person of sufficient previous training to give directions. Instead of such advice being provided, the underlooker was left to gain knowledge from his own experience, and the result was that it was unnecessarily obtained through the occurrence of accidents.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 572, 574.
Boilers and Furnaces, 564, 568, 577.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 557.
Ships and Boats, including their fittings, 570, 571, 575, 587, 590, 596, 602.
Cultivation of the Soil, including agricultural implements and machines, 558, 580, 598.
Food and Beverages, including apparatus for preparing food for men and animals, 555, 567, 584.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 552, 553, 561, 569, 582, 585, 588, 593, 595, 601.
Buildings and Building Materials—*none.*
Lighting, Heating, and Ventilating, 551, 556, 560, 565, 579, 605, 606, 609, 610.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 563, 566, 576, 583, 591, 594, 600, 604.
Metals, including apparatus for their manufacture, 589.
Chemistry and Photography, 586, 611.
Electrical Apparatus—*none*
Warfare, 581.
Letter-Press Printing, 578.
Miscellaneous, 554, 559, 562, 573, 592, 597, 599, 603, 607, 608.

551. H. Fehr. *Improvements in the treatment of mineral oils.* Dated February 27, 1863.

This invention has for its object improvements in the manufacture of petroleums, rock oils, Cuba rock oil, Rangoon oil, or earth oil, by treatment of carbonic or carbonic and chlorine gas together, produced by the action of acid on lime or chloride of lime. The inventor first takes a certain quantity of petroleum, and adds a certain proportion (according to the quality of the oil) of lime, and then adds acid. He allows the gas to act on the oil until the latter has acquired the necessary quality and the desired smell. *Patent abandoned.*

552. E. T. Hughes. *Improvements in machinery or apparatus for doubling or twisting yarn, thread, braid, rope, or similar articles.* (A communication.) Dated February 27, 1863.

For doubling or twisting two or more strands or threads at one operation into a cord or thread, the inventor uses a fly-wheel placed in a vertical position, so as to revolve on its centre, motion being given to it by a driving strap or band on the boss of the fly-wheel, or a small wheel fixed behind it, with a groove or grooves on its periphery to guide the driving strap or band. On the front surface of the said vertical fly-wheel are placed other small wheels, with frames to hold each a bobbin containing the material to be doubled or twisted into a cord, band, or braid, the said small wheels being also grooved to receive a band or strap to give them separate motion; the number of the said small wheels vary according to the number of threads or strands to be twisted together, a spring acting on each bobbin to keep the strands to a regular tension. There is also a fixed pulley with grooves placed in front of the fly-wheel, and on the same shaft, which pulley must have as many grooves as there are strands in the cord, or, in other words, as many grooves as there are bobbins of thread. When a cord is required to have a thread in the middle, a bobbin is fixed in front of the pulley containing the centre thread, which it gives off as required, whilst the other threads or strands lap round the centre thread in a spiral form, the bobbin carriers and fixed pulley being connected to the fly-wheel as already described. Motion may be given to the fly-wheel either by hand or power, which turns from left to right, the bobbin carriers being turned in a contrary direction by means of the strap or belt round the fixed pulley. The two contrary rotations of the fly-wheel and bobbin carriers also produce two twistings simultaneously in contrary directions; the first operates on each strand in the space contained between the bobbin and the point of junction of those strands which unite for twisting; and the second works the twist or cord. The bobbin carriers make as many revolutions on their own axis from right to left as the fly-wheel makes from left to right. The rotation of the fly-wheel produces a separate twisting on the strands, equal to the twisting it produces on the cord, and the contrary rotation of the bobbin carriers also produces a twisting of those strands in the same way equal to the twisting that is produced on the bobbin carriers by the fly-wheel, which shows that the twisting of the strands is double that of the cord. *Patent completed.*

553. J. Carver. *Improvements in the arrangement or fixing of combs in machines employed in the manufacture of bobbin net or twist lace.* Dated February 27, 1863.

The combs employed in bobbin net or twist lace machines are fixed on bars called comb bars. These comb bars, as hitherto used, have been so made and arranged that they do not admit of being conveniently opened or separated from each other sufficiently apart to allow of the introduction and working of the large number of guide bars usually required for producing variegated, ornamental, figured, fancy, or other work, and it has been found that the carriages with the arrangement heretofore employed are liable to enter wrong combs, and thus produce what is known in the trade as wrong gates, thereby injuring the carriages and combs, and involving expense and loss of time. The object of this invention is to remedy these evils. For this purpose, in combination with shortened combs fixed on the comb bars, the patentee uses in each machine an additional set of extra combs, fastened upon and working with each of the landing bars, and the combs which he uses on the comb bars, he forms much shorter than those which have been hitherto used, so as to allow of the effective working of the combs fixed on the landing bars. When the machine is what is called "closed," an end of the carriages—when the carriages are in the machine—will be in the combs on each landing bar, and the carriages will at the same time be in the combs on each comb bar, so that the carriages will be held firmly in the combs on the landing bars, and will, therefore, not be liable to enter wrong combs or produce wrong gates. *Patent completed.*

554. J. A. Coffey. *An improved method of, and apparatus for, controlling and facilitating locomotion, whether on land or on water.* Dated February 27, 1863.

This invention consists in adapting to engines or apparatus for either land or water locomotion, reservoirs or accumulators of power, obtained by the progression of a

carriage or other vehicle, or of a vessel—as, for instance, while a carriage or vehicle is descending hills, or acquired in a vessel under other circumstances, or unexpended at the time of stopping—in which such power may be collected ready to be given out or usefully expended when it is desired to get again into motion, or when it is desired to ascend another hill or incline. *Patent completed.*

555. J. Fry. *Improvements in mashing machinery used in making fermented liquors.* Dated February 27, 1863.

This invention consists—1, in regulating and indicating the supply of malt in and to mashing machinery, so that the mashing shall be effected in a better manner than heretofore. This regulating and indicating is effected by the use of a fluted, corrugated, or ribbed roller, or a roller with boards, projections, or rakes. This roller works in a box or case which has hinged thereto a regulating flap or board, which can be adjusted by means of an adjusting screw or mechanism, so as to regulate the amount of malt to be delivered to the mashing machinery, and by marking the adjusting screw the indicating will be attained. Or this may be effected through the intervention of gearing acting on an indicating dial. At the bottom (or near to the bottom) of this regulating mechanism, a slanting piece may be provided to be inserted into the mouth of the mashing machinery to prevent back action upon the malt and liquor. The mashing machinery it is preferred to make with a longer tube than as ordinarily practised, and placed perpendicularly (though the horizontal position could be adopted) with the revolving rake working therein. Instead of one tube and rake the inventor can connect several tubes and rakes, so as to communicate with each other and form a complete and compact system of mashing machinery. He also purposes jacketing these tubes with steam or hot air, gas, or vapour jacketing, using a thermometer or other indicator for the convenience of the operator. He also prefers to use an octagonal instead of a square shaft or spindle revolving within the tubes, provided with blades instead of rakes, and this will enable rakes or blades to be fixed inside the tube to act as cleaners. *Patent abandoned.*

556. R. A. Brooman. *A new method of and apparatus for boring into water and gas supply pipes, and fixing branch pipes thereon.* (A communication.) Dated February 27, 1863.

This invention consists in a method of and apparatus for boring into water and gas supply pipes, and fixing branch pipes thereon without interrupting or interfering with the supply, as hereafter described. At the point where the supply pipe is to be pierced, the inventor places under and round it a metal strap or clip, brings the ends of the strap upwards, and passes them through flanges, spreading out from the bottom of a tube; between the supply pipe and this tube he places a lead, gutta percha, or other suitable washer, and makes a hermetic joint by tightening the strap by nuts which bear on the top of the flanges, and screw on to the ends of the strap. The tube has fitted in it a tap, and just above the tap the tube is flanged. For the purpose of boring into the supply pipe there is another flanged tube bolted to the tube first mentioned; in the upper part of this second tube a stuffing-box is fitted, and a head for supporting a pressure screw is bolted to flanges on the top thereof. The shaft of a boring bit is carried through the stuffing-box, and through the water or gas way in the plug of the tap fitted in the tube attached to the supply pipe. A boring bit is fitted in the lower end of the shaft, while the pressure screw passed through the head before-mentioned bears on the top thereof; a ratchet brace imparts the necessary motion to the bit, and the supply pipe is thereby pierced. The stuffing-box at the top of the second tube prevents the water or gas escaping. The boring-shaft and bit are drawn up through the passage in the plug of the tap, which is then closed. The parts are removed from the tube in which the tap is fitted, and the tube with its tap and the strap remain permanently attached to the supply pipe. The branch tube or pipe may be extended as required. *Patent completed.*

557. A. Dudgeon, G. F. L. Meakin, and E. E. Allen. *Improvements in the construction of underground railways or subways, and in carriages to be used or worked herein.* Dated February 27, 1863.

This invention may be generally described as a method of constructing the sides and roofing of subways or underground railways by the removal in the first instance of such an amount of earth only as shall be sufficient to lay, embed, or sink such sides and roofing separately, or at the same time, replacing the said earth, and making the roadway good over the subway, leaving the earth between the said sides and under the said roofing to be subsequently excavated and removed in any convenient manner through open cuttings or shafts, at places where no great amount of traffic exists, or where stations may be intended to be formed, and the ground or land be in possession of the company or person constructing the said works. After the excavation or removal of the earth in the tunnel or subway shall have been effected, the bottom may be formed and made good, and the subway consequently finished in considerably less time than would be possible were the whole of the earthwork removed down to the base or floor of the subway at one and the same time. The invention consists—2, in constructing the carriages to be used or worked in subways constructed as above described. Great diminution in the height of the same may be made, by forming the floors of the said carriages nearer to the level of the rails, and below the axles of the wheels, the said axles passing under or between any pair of seats in a suitably constructed passage made from side to side of the carriage. The wheels of such carriages the patentees propose to place in recesses formed in the sides of the carriages, such recesses being open in front, and made to contain the springs and grease-boxes and break blocks. To enter such carriages no platform would be required, or one raised a few inches only from the level of the rails, and a waste of vertical light of from 2 to 3 ft. avoided. The back of the recess for the wheels would in this case take the place of ordinary horn plates. *Patent completed.*

558. W. Gray. *Improvements in the manufacture of beaters for thrashing machines.* Dated February 27, 1863.

This invention is not described apart from the drawings. *Patent completed.*

559. W. Clark. *Improvements in pumping and forcing water, and in apparatus for the same.* (A communication.) Dated February 27, 1863.

This invention is not described apart from the drawings. *Patent completed.*

560. V. D. Delahaye. *Improvements in apparatus for cleaving and excavating pit coal and rock or earth.* Dated February 27, 1863.

This invention has for its object the more regular, rapid, and economical execution of the cuttings required to be made for the separation of the mass of pit coal and rock or earth intended to be excavated, and for boring holes therein. For this purpose the patentee employs a carriage and travelling tool combined with suitable guiding apparatus. The apparatus consists of a frame or frames, adjustable as to height or length, with the two ends capable of being caused by the pressure of a screw to hold firmly against the top or the partition walls of a mine or other cavity required to be excavated. The frames form guides for slides worked by means of a lever and ratchet, and a pulley with a cord round it, such slides having connected to them by means of suitable cross-framing the carriage for the travelling tool, which carriage has holes in it for the insertion of a forked bar or bars, by means of which the carriage may be worked as required along the cross-framing, friction rollers being applied to the carriage in order to facilitate its motion thereon. By means of the foregoing arrangement of apparatus the operations of the workman will be made to consist in guiding the travelling tool, which in some kinds of excavating operations will work after the manner of a plane, whereby he will be relieved from the more trying operation of working as usual with a pick, and in the operation of boring the tool will be readily turned as required. *Patent completed.*

561. J. H. Johnson. *Improvements in machinery or apparatus employed in the preparation or treatment of hemp and other textile materials.* (A communication.) Dated February 27, 1863.

This invention consists in a peculiar construction and arrangement of feeding apparatus for feeding the various machines employed in rendering the fibres of hemp and other textile materials fine and supple. It is proposed to construct the feeding apparatus in such a manner that tufts or handfuls of the fibrous material will be introduced between and amongst the layers or lap already formed upon the feeding table or endless cloth, with a view to the formation of a fleece or lap. This lap is thus composed of several successive layers, so disposed that each fresh layer, as fast as it is introduced into the main lap at a certain point, will be covered both above and below by the layers already introduced, and forming the feeding lap or layer of the machine. The improved feeding apparatus consists, essentially, of two open frames hinged upon the axis of the fluted feeding roller, which presses upon the lap contained on the feeding surface or table. One of these frames is rather shorter than, and works within, the other, but on the same centre of motion. By successively lowering and raising these frames, the handfuls or tufts will be deposited in regular order in the layer on the table. After placing a certain quantity of the fibrous material to be operated upon under the cross bar of the longer frame, which is turned down for that purpose, the shorter frame is elevated in order to divide the layer which is about to pass under the grooved feeding roller. Another handful of fibre is now interposed by placing it over the cross bar of the longer frame, when it is presently drawn in under the roller along with the rest of the layer. By this mode of feeding, whereby the handfuls are introduced into the middle of the lap or layer, greater regularity of feed is obtained, and the clogging or choking of the machine is prevented. *Patent completed.*

562. B. West. *An improvement in metallic pens.* Dated February 28, 1863.

This invention consists in making each pen double—that is to say, the piece of metal of which a single pen is now made is so shaped and cut as to form two pens, one at each end of the piece of metal. *Patent abandoned.*

563. G. Royle. *A new or improved apparatus for creasing or marking rouches.* Dated February 28, 1863.

We cannot here give space to the details of this invention. *Patent abandoned.*

564. W. Hadfield. *Improvements in steam boilers and in the arrangement of flues in connection therewith.* Dated February 28, 1863.

This invention is applicable to boilers with internal flues, the objects being to impart strength, to obtain a larger internal and external heating surface, and to arrange the flues in the most advantageous manner to equalize the heat, so as to avoid or reduce the injurious effects of unequal expansion and contraction. In performing the invention, the patentee places the fire grate or grates in one or more flues, which deliver the products of combustion through openings at each side of the boiler into side flues, which are brought back towards the front of the boiler, and then unite in a flue passing under the whole length of the boiler. The products of combustion then enter an internal flue or flues which deliver them through openings at each side of the boiler to side flues which are in communication with the chimney. *Patent completed.*

565. J. W. Friend. *An improved gas meter.* Dated February 28, 1863.

This invention consists in employing, in lieu of the ordinary measuring drum or chamber, a vessel of cylindrical form, mounted upon a suitable stand, and fitted with a piston, so as to work freely within the same, and admit of being actuated by the pressure of gas through the meter. The said piston is packed with mercury, and provided with a piston rod passing through a stuffing box on the top or cover of the cylinder, to which also two parallel plates are fixed. These parallel plates carry a horizontal spindle, which receives motion through the medium of toothed wheel and pulley gear direct from the piston rod; a four-way tap is employed in connection therewith, as also a small gravitating lever and alternating stop stud motion, by the rising and falling of which the plug of the tap is carried round to the quarter port, and again on the reverse side in a like manner at each up-and-down stroke of the piston, whereby the gas is admitted and regulated to the meter and the indicators set in motion. *Patent abandoned.*

566. F. Fabra. *New application and combination of materials to be employed in the manufacture of skirtings.* Dated February 28, 1863.

This new material for skirtings is formed by weaving devices in imitation of "sewed muslins," the said devices being either woven in the piece of skirting, or attached by sewing. *Patent abandoned.*

567. J. Maxfield. *Certain improvements in brewing, and in apparatus employed therein.* Dated February 28, 1863.

This invention is designed for the purposes of keeping the yeast arising from malt liquors separate from the liquor as it rises during the process of fermentation, and for retaining the carbonic acid gas in the malt liquor, and preventing the too free entrance of air. The improvements consist in the employment and use of a cover or lid floating upon the surface of the malt liquor, and furnished at the edges with india rubber or other elastic medium to form an air and water tight joint between the edge of the cover and the inside of the vat in which the liquor is placed to ferment. This floating cover is provided with a tube extending upwards, through which the yeast passes and falls on the outside of the cover. Valves are also employed in the cover, opening inwards, and connected with tubing by which any liquor the yeast may contain passes again into the vat. The patentee also employs within the vat coils of piping supplied with hot or cold liquid to regulate the temperature of the liquor, as usual, and taps for drawing off the malt liquor from beneath the cover when the barm is separated. By the use of this floating air-tight cover the height of the liquor in the vat becomes immaterial, and the free escape of the carbonic acid gas is also prevented. *Patent completed.*

568. S. Williamson. *Improvements in the construction of furnaces.* Dated February 28, 1863.

This invention applies to furnaces for steam boilers, furnaces used for the conversion of iron into steel, and to every other kind of close furnace having a flue to carry away smoke or the products of combustion. The improvements consist of an arrangement of perforated bricks and air passages introduced into bridges beyond the grate bars, whereby combustion is promoted and smoke consumed (and in cases where applied to steam boilers, without the disadvantages which arise from bringing cold air in contact with the hot surface of the boiler). *Patent completed.*

569. D. Collinge. *Improvements in machinery or apparatus for cleaning, steaming, and preparing cotton and other fibrous fabrics to be spun.* Dated February 28, 1863.

This invention consists in attaching to the machine generally known as the Oldham willow, the ordinary fan, with additional apparatus for the purpose of more effectually cleaning out and steaming the fibrous materials. The patentee attaches to the willow two endless bands or aprons made of laths or other suitable material. One of the said bands or aprons acts as a feeder, and the other as a deliverer, both of which are rendered self-acting by suitable gearing. An attendant is required to feed the material to the willow, which falls on the feeder, and passes through the willow to the delivery band, and is conveyed to a fan in motion, which is surrounded by a grid to allow the dirt or refuse extracted by the quick motion or revolution of the blades to fall through it. The material thus cleaned and opened passes through the fan into a wire tube, which conveys it into a steam chamber, any remaining refuse or dirt falling through the said tube, giving the fibrous material an additional cleaning. He supplies steam to the steam chamber by means of pipes, so that, as the fibrous material enters the chamber from the wire tube, the steam from any convenient number of pipes in different directions penetrates and saturates it, thus cleaning and steaming the fibrous materials in one continuous operation. *Patent completed.*

570. E. Paine. *Improved apparatus for facilitating the cleaning of vessels' bottoms while afloat.* Dated February 28, 1863.

This invention consists of an oval compressed egg metal, or other suitably shaped hollow vessel, formed of iron or other suitable material, surrounded on the outside by a series of brooms or brushes, made from bristles, cocoa fibre, piassava, or other suitable material, cocoa, india rubber, or other suitable matting, alone or in combination with brushes or brooms. The sides and ends the patentee provides with suitable eyes, or other means for connecting guy-ropes thereto, in such a way that the said eyes will not come into immediate contact with the ship's sides or bottom when in use, thereby preventing injury thereto. One of these guy-ropes he connects to the front, and another to the rear end, and one to each side of the hollow vessel. The end guy-ropes he prefers to connect to the said ropes by bridle ropes. This improved apparatus may be used as follows:—One of the end guy-ropes is carried through a block attached to the under side of the bowsprit or jibboom end, and one of the side guy-ropes is passed under the vessel's bottom and through a block on the fore yard and on to the deck; the rear guy-rope is now carried outside of the vessel, clear of the rigging, through a block attached to the end of the mizen-boom or other spar projecting over the vessel's stern, and bent to the deck. The hydraulic scrubber is next thrown overboard, and the guy-rope passed under the vessel's bottom hauled on and let go alternately, as often as may be found necessary. The fore guy-rope may now be slacked off a little, and the yard slightly braced up and the operation

posted all along one side of the vessel, removing the side blocks on the fore yardarms to the main yardarm, and so on, after which the same operation is to be performed on the other side of the vessel. To avoid the probability of the guy-ropes fretting in passing under vessels having deep and sharp-edged keels, the patentee has designed several modifications of a creeper to travel along the keel, which creeper is provided with a "live" or "dead sheave" or pulley, as well as an antifriction chain or rope, in lieu of the ordinary guy-ropes. *Patent completed.*

571. T. E. Symonds. *Improvements in the construction of screw-propelled ships, and in the arrangement and mode of disconnecting, withdrawing, and lifting screw propellers.* Dated February 28, 1863.

This invention relates to twin or double-screw ships built of iron, and having one or more keels, each screw being overhung, or having no outer bearing. The invention will be fully described in a future number of this journal. *Patent completed.*

572. J. Penn. *Improvements in escape or relief valves for the cylinders of marine and other steam engines.* Dated February 28, 1863.

According to this invention, the patentee applies instead of weights and springs the pressure of the steam to keep the escape or relief valves in their seats. For this purpose he places the valves enclosed in cases on any convenient part of the cylinders sufficiently high for any water to pass by means of pipes into a separator in the main steam-pipe of the engine, or to the main steam-pipe itself, where the position of the latter will admit of the arrangement. It will be seen that the valves are kept in their seats by the difference between the pressure of steam in the main steam-pipe and the cylinder, and also in consequence of the difference of area between the outer and inner surfaces of the valve. *Patent completed.*

573. J. Courtenay. *Improvements in obtaining motive power.* (A communication.) Dated February 28, 1863.

This invention consists in producing motion by changing (increasing or diminishing) the specific gravity of an elastic fluid, the change being effected by revolving weights. *Patent abandoned.*

574. E. Hayes. *Improvements in supplying water to surface condensers of marine engines.* Dated February 28, 1863.

For the purposes of this invention, in constructing and arranging surface condensers on board ships or vessels propelled by screw or submerged propellers, the outer ends of the outlet pipes of the surface condensers are placed near the screw or the submerged propellers. The supply of the water to the surface condensers is by pipes passing through the ships or vessels, so as to admit of a free flow of water to the surface condensers. By thus constructing and arranging the surface condensers of marine steam engines, the action of the submerged or screw propellers will cause the condensing water to be constantly removed from the outlet ends of the outlet pipes of the surface condensers, and the pumps heretofore employed to facilitate the passage of the condensing water through the surface condensers may be dispensed with. *Patent completed.*

575. S. Bateman. *Improvements in the manufacture of wire rope and cordage, and in the machinery employed therein.* Dated February 28, 1863.

This invention is not described apart from the drawings. *Patent completed.*

576. G. Haseltine. *Improvements in sewing machines.* (A communication). Dated February 28, 1863.

These improvements are situated below the bed-plate of the machines, and relate to a hollow grooved revolving hook used instead of a shuttle; to a flanged spool holder which works in the groove on the inside of the hook; to the use of an expanding and contracting spindle for the lower spool; to a spool guard, which is constructed to prevent friction of the needle-thread upon the under thread and spool; to a hook for taking up and controlling the slack of the needle-thread as it passes from the point of the revolving hook, thereby preventing its being tangled; to the means and manner of regulating the tension of the lower thread; to using the lower thread direct from the spool; to an elastic shuttle or knot stitch; and to the manner of combining and arranging the said hook, spool holder, and guard. *Patent abandoned.*

577. O. Murrell. *Improved arrangements for generating steam in steam boilers and other vessels, and for heating the liquid contents thereof.* Dated March 2, 1863.

This invention consists in causing the water in steam boilers to pass from the lower part thereof through a series of horizontal bent pipes, constituting the fire bars of the furnace of the boiler, the said pipes extending in a longitudinal direction up to the bridge of the furnace, and then in a zig-zag direction across the face of said bridge. Thence a smaller pipe passes from the end of the uppermost of said zig-zag pipes to the front of the furnace, and turns upwards outside the front of the furnace, and is finally connected to the boiler at the front thereof at a point above the level of the water therein. The pipe employed to convey the water from the boiler, as above stated, passes outside of the boiler, and extends downwards nearly to the bottom of the ashpit, then bends upwards, and is connected to a cross pipe situated within the furnace, and to which the series of hollow fire bars before mentioned are connected. By means of this bent pipe throttling of the water in the said bars or pipes is prevented. The aforesaid pipes are fitted with suitable cocks for feeding, stopping, turning-off, and gauging or testing the state of the heated water passing through the same. An important feature in this invention consists in adapting underneath each of the longitudinal pipes in the furnace a V-shaped plate or shield for protecting the pipes from the action of cold air. *Patent completed.*

578. F. Tolhausen. *Improvements in cloth blankets, and other fabrics to be used in machinery for printing fabrics, paper-hangings, and letter-press.* (A communication.) Dated March 2, 1863.

This invention relates to the general and systematic use of flock, floss, fancy or waste silks, for those cloths or fabrics which are employed in covering printing or inking rollers, printing tables, and the like implements. When used for printing or inking rollers, the improved cloth is made in two layers of twilled fabric of silk floss and other similar material, which are united by a layer of india rubber laid on in the liquid state. When used for printing blankets ("doubliers"), which are lying under the fabrics and papers in the process of printing, a plain shed will answer the purpose, the material employed in both cases being silk of the kinds described. *Patent abandoned.*

579. J. W. Burton. *An improved mode of refining and purifying oils.* Dated March 2, 1863.

The patentee claims—1, the use of mimotannic acid for refining and purifying oils and other fatty matters, as described; 2, the use for the same purpose of methylated spirit in combination with mimotannic acid, as described; and, lastly, the use of nitric and sulphuric acid, and the gases derived therefrom, for refining and purifying oils, and other fatty matters, when such oils or fatty matters have been previously purified by means of mimotannic acid or similar tannin matters, as described. *Patent completed.*

580. A. F. Pagny. *A new agricultural implement for cultivating tubercles, roots, and all oil plants.* Dated March 2, 1863.

The agricultural implement forming the subject of this invention is a ridge or bouting, and, at the same time, a roller plough. It is composed of a ploughshare with double mould board, smaller than for ordinary bouting ploughs, and of four conical rollers acting on the inclined plane of the ridges. The share (the main object of which is not the bouting or ridging) breaks the subsoil, cleans the water furrows, and thus prepares the work of the rollers which follow it. *Patent completed.*

581. G. Hawksley and T. Bissell. *Improvements in powder chargers.* Dated March 2, 1863.

This invention consists in constructing the chargers of powder flasks—that is, the appliances fixed on powder flasks, for measuring and pouring the charge of powder into guns and rifles. Hitherto, there have been two chief parts in such articles—a fixed tube or cylinder, and a moveable tube with a contracted mouth. The moveable tube has had notches cut in it, and an inclined or straight slit, into which the notches upon the moveable tube has been set for use by a pin or stud inserted in the fixed tube entering one or other of the notches in the moveable tube; there has been no means, however, of regulating the capacity of the charger to any point intermediate between any two notches. Now, this invention consists in fitting an upright parallel with the fixed tube, in connecting the moveable tube to a bar having an aperture through it into which the upright enters, and on which it is free to slide up and down, taking the moveable tube with it. A set screw attached to the bar on the moveable tube fixes it at any desired height on the upright. The patentees mark graduated scales of grains and drams on the fixed tube, and make apertures in the lower part of the moveable tube to read the scales. In some cases they dispense with the upright, and apply a set screw to the moveable tube to fix it at any height on the fixed tube. Another part of the invention consists in fitting a spring lid, which moves horizontally to close or open the mouth of the moveable tube. This horizontal spring lid is also applicable to powder-flask chargers however otherwise constructed. *Patent completed.*

582. E. Habel and E. Luckow. *Certain improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous substances.* Dated March 2, 1863.

This invention is carried into effect as follows:—The spindle upon which the cop or bobbin is formed, has a bearing in a footstep in a copping or lifting rail, and is supported at a higher point by a hollow stud, upon which revolves a brush terminating in a cylindrical case, which re-encircles the spindles, and is sufficiently wide to admit the formation of a cop or bobbin, or a tube or bobbin within it, and is driven by a band passing round a pulley thereon. From the upper edge of this case a wire extends, either short and simply bent, or formed like an arch or cone: when the arch is employed it is provided with an eyelet (formed in a piece of metal by a round hole, and a slot diagonal to it) at the apex, and others at convenient distances on the wire if required, by which means the yarn passes, and is spun directly from the drawing rollers to the cop or bobbin. The second portion of the invention is particularly applicable to spinning-cops, and consists, first, in the employment and use of a short spindle, having a plate or washer at the lower end; the spindle is steadied at its upper extremity by entering an aperture in a bent wire or rod extending above the spindle, somewhat in the form of an arch or cone, the ends of such wire being secured in a collar which is attached to the driving pulley, and the lower end of the spindle is steadied by entering an aperture in a vertical rod or elongated footstep passing through the stud supporting the whole in the framing. A third part of the invention, consists in a novel method of effecting a drag on the solid spindle by the means of a curved or straight piece of metal, upon which the plate or washer bears, and which is attached to and actuated by, the means of a wire passing down a slot in the rod or spindle footstep, and terminating in a tailpiece formed at right angles, and which are connected together by a rod or wire throughout the length of the machine. The effect of the drag upon the washer and spindle will decrease as it approaches the spindle or centre, and increase as it is turned outwards to come in contact with a longer surface. The drag is applicable to all descriptions of spinning and doubling machinery, where any drag is employed. The copping motion may be obtained by cams as in the ordinary manner, or by the improved means of a rotating or semi-rotating disc having two studs acting upon a bell crank lever, such studs being caused to diverge from the centre of the disc in a self-acting manner by means of right and left handed screws and spur wheels, oval eccentric spur gearing or cam being employed to drive the aforesaid disc, by which means a variable motion is obtained to "shape the cop." A fourth part of the invention relates to a novel arrangement and construction of apparatus to act as a guide for delivering the yarn on to the cop or bobbin, and consists in a light metallic ring peculiarly formed so as to encircle each vertical wire of the aforesaid arch or cone, so as to prevent unequal strain. This ring is furnished with an eye or hook for the yarn, and revolves with the cone or arch, and within a metallic channel or case which rises and falls like the ordinary lifting rail, and thus the yarn is wound on the cop. *Patent completed.*

583. T. Taylor. *The manufacture of a new or improved fabric, and its application to the formation of ornaments for fire-stoves and other decorative purposes.* Dated March 2, 1863.

This invention consists in the manufacture of a slight woven fabric of dressed, polished, or stiffened cotton, yarn, or thread, or other suitable material, which fabric, when cut into strips, presents a fringe formed by the weft material, on each side of the body or warp which lies down the centre. The inventor twists this slight double fringe, which imparts to it a light feathery appearance, and he applies it to the formation of ornaments for fire-stoves and other decorative purposes. *Patent abandoned.*

584. O. Garton. *An improved method of applying heat in the manufacture and refining of sugar, and in malting, hop drying, brewing, distilling, and vinegar making.* Dated March 2, 1863.

This invention consists in applying hot water or other fluid as the heating medium, the heat being sustained by self-acting circulation through the pipes from a boiler either contiguous to, or at a distance from, and at a lower level than, the sugar to be acted on. *Patent completed.*

585. J. S. Wells. *Improvements in the manufacture of stockings and other looped fabrics made in knitting machines.* Dated March 2, 1863.

For the purposes of this invention, in order that the selvages and seams at the back, and the sevages and seams at other parts of stockings, and also the selvages and seams of socks, drawers, waistcoats, and other articles made in knitting machines, may have greater strength imparted to them, an additional thread layer or carrier is applied at each selvage to a knitting machine, or other provision is made for employing an additional thread at each of the selvages, which thread is laid on to the needles of the machine at and near the selvages together with the thread or threads which is or are laid from selvage needle to selvage needle to produce the main body of the fabric, so that, at and near the selvages, the fabric will be composed of more threads than the intermediate fabric. *Patent completed.*

586. W. Clark. *Improvements in preparing and obtaining photographic impressions, and in the application of such impressions.* (A communication.) Dated March 2, 1863.

Permanent or unchangeable photographic impressions have already been produced by what are termed carbon processes—one of which is based on the employment of matters of a gummy nature, with the addition of a solid bichromate; and the other a mixture of perchloride of iron and tartaric acid, applied only on glass. These processes, which require the employment of negatives, are very expensive and incomplete when acting directly on paper. The improved processes of this invention are based on the application of chemical actions, as applied hitherto, or otherwise, in taking photographic impressions, by means of which the inventor obtains impressions directly on paper—that is to say, he reproduces a positive image from a positive. *Patent abandoned.*

587. T. E. Symonds. *Improvements in the apparatus for steering ships.* Dated March 3, 1863.

This invention relates—1, to a novel mode of constructing and working rudders for steering ships and other vessels, by which additional surface and increase of rudder power can be given when required; and, 2, to the mechanical means employed for transmitting the motion of a steering wheel and the power applied thereto to the rudder of a ship, by which jerking and undue straining are avoided, a superior action of the tackles and intermediate connections effected, the risk of wringing or twisting the rudder head prevented, and by which, also, fewer hands are enabled to steer a ship in the heaviest weather. The invention will be described in a future number of this journal. *Patent completed.*

588. T. Emmott. *Certain improvements in mules for spinning and doubling.* Dated March 3, 1863.

The object of this invention is to prevent snarls, and it consists in certain improved combinations of machinery for governing the rise of the counterfaller, and for putting the strap on to the driving pulley at the commencement of a fresh stretch. In performing this invention, the counterfaller is connected to the strap guide of the driving pulley by means of a sliding bar, or a pulley with a chain and weight or spring, for the purpose of bringing the driving strap at the proper moment on to the driving pulley, thus preventing the yarn from becoming slack, and, consequently, preventing snarls, which are produced when the yarn is allowed to become slack when the carriage is near the drawing rollers. *Patent abandoned.*

589. R. Saunders. *Improvements in metal sheathing for ships and vessels, and in the securing of such sheathing thereto.* Dated March 3, 1863.

The under side of the sheathing, or that intended to be next to the planking or skin of the ship or vessel, is to be made of uneven surface, or ridged, so as to provide at intervals thicker portions to admit of countersinking the heads of the nails or screws necessary for securing the said metal or sheathing to the ship or vessel. And in order the better to secure the sheathing, the inventor screws or nails on strips of metal fore and aft-wise to receive the edges of the sheathing. Between the intervals aforesaid, he fills in thin cork, or any other soft material. By these means he is enabled to produce a uniform outer surface, such as will be conducive to the speed of the ship, besides avoiding the necessity of using so many nails as are at present employed. *Patent abandoned.*

590. G. F. LYSTER. *Improvements in mooring buoys.* Dated March 3, 1863.

This invention consists in constructing mooring buoys in such a manner that, instead of being attached to the mooring chain, and serving as the point of attachment for the vessels, the buoy acts simply as a float or carrier for keeping the end of the mooring chain above water, the latter being in no way attached to the buoy, beyond passing through an aperture formed in the same, and when not attached to a ship's cable, being prevented from falling through the aperture by the larger dimensions of the mooring ring. *Patent completed.*

591. R. H. JONES and J. ABRAHALL. *Improvements in bracelets and brooches.* Dated March 3, 1863.

This invention consists in so constructing bracelets and brooches that the locket, or part carrying the stone or principal ornament, may be reversed without removing the bracelet from the arm or the brooch from the dress. The inventors engage the ends of the locket or frame axis in holes formed in two bars capable of sliding in tubes outside the said ring. The said tubes are at right angles to the plane of the locket. By this arrangement, the locket or frame is capable of being raised above the ring, and the locket or frame may be reversed or swivelled without removing the bracelet from the arm or the brooch from the dress. *Patent abandoned.*

592. G. DAVIES. *Improvements in polishing or giving a lustre to soap, and in the apparatus employed in such process.* (A communication.) Dated March 3, 1863.

The essential feature of this invention consists in the employment of steam, either pure or charged with some perfume, which it takes up on passing through a fabric or fabrics impregnated with perfume or aromatic substances. This steam is brought into contact with the toilet or other soap either before or after moulding, in order to effect the polishing of the surface thereof. *Patent abandoned.*

593. J. HENDERSON. *Improvements in machinery or apparatus for the manufacture of carpets and other piled fabrics.* Dated March 3, 1863.

This invention relates—1, to an improved method of effecting the crossing of the surface warp threads in the manufacture of pile carpets and other piled fabrics, when such pile is formed by the aid of longitudinal lines. For this purpose, the patentee prefers to employ longitudinal wires or instruments of the character of those described in the specification of letters patent granted to himself and Jas. Broadley, bearing date the 3rd day of August, 1861 (No. 1931). These instruments have points or raised portions on them between the end of the batten and the healds when the lathe or batten is in the back. Behind the lathe he applies a comb with long thin flat teeth, and as many of them to the inch as there are longitudinal pile wires. This comb is placed in front of the heald, and immediately behind and close to the joints referred to on the longitudinal pile wires. Each longitudinal pile wire, with its corresponding warp threads, passes between two teeth of this comb, and the teeth are of a length that will admit of their lower ends passing below the lower warps when the shed is open, while, at the same time, the bar in which the teeth are fixed is sufficiently raised above such points on the longitudinal pile wires as to allow of the pile warp threads being elevated to the desired extent above those points. The comb bar is capable of endway motion, in order that, when the pile warp threads are required to pass down on the right side of the wires, the comb may be moved to the right until its thin teeth bend so much as that they slightly pass to the right of the points on the wires, and so as to conduct the pile threads safely and securely past those points; the surface warp heald or harness is now depressed, and the threads are conveyed down the desired side of the wire. If the comb be moved to the left, and the warp threads be depressed, they will, in like manner, be conveyed securely down the left side of the wire. *Patent completed.*

594. G. PRICE and W. DAWES. *Improvements in burglar-proof safes and strong-room doors and frames.* Dated March 3, 1863.

The patentee claims—1, the method or principle of dispensing with the large lock and bolts upon the door, and using in lieu thereof the moveable security portions or "works" in the body or frame of the safe or door, as described; 2, the use, application, and methods of employing hard pig or white pig iron for the purpose of rendering safes and strong-room doors drill proof; 3, the method of protecting the interior of the small lock by electro-coating from the action of acids. *Patent completed.*

595. J. SIBERT. *Improvements in winding and measuring lace.* Dated March 3, 1863.

This invention has for its object improvements in apparatus for winding and measuring lace. The invention is applicable to that class of winding and measuring apparatus known as measuring jennies, wherein the winding is on to forks. For these purposes motion is communicated to the axis of a fork similar in respect to the winding blades or prongs to those ordinarily used, but there are two other prongs at right angles to those on which the winding takes place; these additional prongs are set at a less distance apart than the ordinary ones, and generally somewhat more than half their distance apart. The lace to be wound and measured is conducted over a guide rail, and between two pins or guides, on to the surface of a cylinder, which is hollow and made as light as may be. The periphery or surface of the cylinder is covered with woollen cloth, velvet, vulcanized india rubber, or other suitable holding material. The lace then passes between the surface of the cylinder and a small pressing roller, which is kept pressed up to the cylinder. The lace then descends between two guiding surfaces, between which the lace will not descend without being drawn through, at the same time the two surfaces do not offer such resistance to the passage of the lace as to require any material force to draw it through the space. By this means, if the lace becomes slack between the cylinder and the guides, such slack will not extend to the fork on to which the lace is wound. The rotation of the fork draws the lace through the space between the guides and off the cylinder, by which, when the space of winding is considerable, the cylinder is liable to overrun and produce slack. The two guides are arranged to be readily adjusted to and from the cylinder, and so as to readily admit of their distance from the cylinder being varied. On the axis of the cylinder there is a worm or screw wheel, which takes into and drives a worm or screw wheel which gives motion either to a graduated dial or to a pointer, acting with a fixed graduated dial. *Patent abandoned.*

596. G. LAMB. *Improvements in apparatus for recording the revolutions of the propelling shaft of a steam ship or vessel.* Dated March 3, 1863.

In order to record the number of revolutions of the propelling shaft of a steam ship or vessel, and the time during which the revolutions are made, and whether forward or backward, apparatus is combined and used in the following manner:—A good chronometer or suitable form of time-keeper is arranged to give motion to a strip of paper at a uniform speed, and to mark it at intervals, say, one or more times each minute during which the propelling shaft is in motion. The strip of paper is progressively wound on to an axis as it is delivered from the apparatus, which gives motion thereto, and causes it to pass the marker put into motion by the chronometer or time-keeper as before mentioned. This taking up and winding of the strip of paper may be, by a train of wheels, put in motion by a spring or by other suitable apparatus. The strip of paper before passing to the marking apparatus is wound on to an axis, and sufficient friction is applied to prevent the strip of paper unwinding faster than it is drawn off by the apparatus in connection with the time-keeper. The propelling shaft of the ship or vessel, by means of a projection, gives motion to a marker or marking apparatus at each revolution, so that the strip of paper may be marked each revolution when the vessel or ship is being propelled forward, but such apparatus is arranged not to act or mark when the propeller shaft is rotated in the opposite direction, another marker or marking apparatus being applied, which is acted on only when the propeller shaft is propelling the ship or vessel sternwise. *Patent abandoned.*

597. T. ERICH. *Improvements in machinery for pressing peat.* (A communication). Dated March 3, 1863.

This invention has for its object improvements in machinery for pressing peat. For these purposes two horizontal cylinders or rollers are used, which are geared together by cog-wheels on their axes. The peripheries of these cylinders or rollers are composed of numerous parallel bars placed at short distances apart, so that the water pressed from the peat may pass freely between the bars into the interior of the cylinders or rollers; it is received into suitable gutters, and conducted thereby out of the cylinders or rollers. The sides of the bars are not radial from the centres of the cylinders, but incline downwards to give freer passage to the water. Two strong endless fabrics are employed, one to each of the cylinders, and to the selvage of these fabrics are fixed strong cords, by which and by guide pulleys the fabrics are held extended as they are caused to circulate by the motion of the two cylinders or rollers. On the outer side of one of the endless fabrics parallel transverse ridges of wood or other suitable material are fixed, by these the surface of the endless fabric is divided into parallel hollow spaces, which are further enclosed at their ends by means of flexible ridges of leather, or other suitable material, placed parallel with the selvages of the fabric, and near thereto. The transverse ridges extend up to, but not beyond, the ridges which are parallel with the selvages. The peat is placed in a hopper, the lower end or outlet of which comes between the two fabrics where they meet, and descends between the pressing cylinders or rollers, and the ledges on the one endless fabric assist in carrying down the peat between the cylinders or rollers. By these means the peat is pressed into a sheet having transverse indentations on one side. The sheet of compressed peat, on leaving the fabric, is conducted to circular saws or cutters which cut the sheet longitudinally. The endless fabrics are cleansed by means of jets of water, which are capable of being moved to and fro across the surfaces of the two fabrics. *Patent abandoned.*

598. D. B. PARSONS. *Improvements in reaping and mowing machines.* (A communication.) Dated March 3, 1863.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

599. B. S. COHEN. *Improvements in apparatus for protecting the points of pencils.* Dated March 3, 1863.

In order to protect the points of pencils where the lead or other marking material is enclosed in wood, and where the points are formed by cutting away the wood, a sliding elastic tube (by preference of metal) is applied. This tube is split longitudinally, and has a tendency to close on and embrace the pencil with an elastic holding, so as not readily to be moved along the pencil when out of use and in the pocket. In addition to the tube embracing the pencil by its elasticity, there is an internal spring (or springs) which rests against the conical or inclined shoulder, which is formed by the cutting away one end of the pencil; hence when the pencil is out of use, and the guard tube has been slid over the point thereof, this spring, or these springs, will press on such conical end or shoulder, and prevent the tubular guard being forced back along the pencil. *Patent completed.*

600. W. PARSONS. *Improvements in dining tables.* Dated March 3, 1863.

This invention consists in the application of certain apparatus for extending and contracting the framework of such tables for the purpose of enlarging or reducing their size. The inventor employs for this purpose a system of cross levers such as are usually denominated lazy tongs, the one end of such system of levers being connected with the one end of the table, and the other with the other end. For ordinary or small-sized tables he prefers to fix the pivot of the first pair of cross levers to the table; and to the extreme end of such first pair of levers he applies a nut in which a screw works; this screw is of some 8 or 10 in. in length, and rotates in the end frame of the table, where it is held and prevented from moving in the direction of its length by suitable collars. This screw is turned by a suitable key, and the action on the nut causes the cross levers to extend or collapse, and with them the table to extend or contract. *Patent abandoned.*

601. J. POLLARD. *Improvements in warp dressing, and in apparatus connected therewith.* (A communication.) Dated March 3, 1683.

This invention consists in the combination of warp dressing apparatus hereinafter described with the loom used for weaving fabrics, in such a manner that the processes of weaving and dressing the warp being so woven are effected simultaneously. For this purpose the inventor causes the threads (after passing over what is ordinarily termed the warp beam), guided by a reed, to pass between two rollers, the lower roller being covered with flannel, or other similar material, and partially immersed in a suitable trough or vessel containing the size and dressing in the direction of the healds of the loom, the threads of the warp being kept even and in sufficient tension by means of two small rods (over and under which they are crossed alternately) affixed to an adjustable bar attached to the loom for that purpose. Or the threads may be caused to pass over the upper one of the rollers before alluded to, and which, in this case, would be covered with flannel, or other suitable material, and receives the size or dressing from the lower roller revolving in a trough, and not necessarily covered with flannel or similar material. To the ordinary crank-shaft of the loom is attached a brush or brushes of suitable breadth to remove any superfluous size from the warp threads as they pass over that part of the loom where the shaft is placed, the revolving-brush being cleansed in turn by contact with a brush fixed to the trough or any convenient part of the loom. A fan may be attached to the crank-shaft to partially dry the warp threads; but this he does not insist on, as experience has proved it not essential. The component parts of the above described warp dressing apparatus are fixed by preference in the framework of the loom, forming with the loom a combined apparatus for dressing warps and weaving fabrics simultaneously. *Patent completed.*

602. C. M. PALMER and J. MCINTYRE. *An improved mode of applying and fastening metal sheathing to the bottom of iron ships or vessels, and to iron for other uses.* Dated March 4, 1863.

This invention consists in fixing to the iron plates of the ship or vessel, or to iron for other similar uses, strips of metal, which the patentees prefer to be of galvanized iron, in which strips are inserted rivets of copper or other suitable soft metal, such rivets protruding from the strips in such a manner as to admit of strips of copper, "Muntz metal," zinc, or other sheathing previously punched, being applied thereto, and held thereby as required. By this arrangement the strips fixed to the vessel form carriers for the sheathing, and obviate the necessity of perforating through the ship's side. The strips are double—that is to say, there is one outer and one inner strip, and they are applied to the plates of the vessel by means of screws or rivets passing through both strips, and into the said plates, the copper rivets having been previously inserted in an opposite direction in the outer strip. The sheets of copper, Muntz metal, zinc, or other sheathing, are put on to the projecting copper rivets with their edges overlapping, so that the ends of two sheets are held by one row of rivets, and tarred felt, blair, or other similar non-conducting material is inserted between the iron plates of the vessel and the copper or other metal sheathing. The projecting portions of copper are then hammered so as to securely rivet them. *Patent completed.*

603. J. F. GITS. *An improved furnace for the revivification of animal charcoal.* Dated March 4, 1835.

This invention is not described apart from the drawings. *Patent completed.*

604. A. P. JEUNE. *Improvements in spring bed bottoms.* Dated March 4, 1863.

Provisional protection has not been granted for this invention.

605. J. DE KEYSER. *Improvements in treating petroleum oil and in the combination thereof with other oils for lubricating and other like purposes.* Dated March 4, 1863.

This invention consists in subjecting petroleum oil to one or more distillations, so as to clear it from impure and tarish matters, using soda to clear it from acids, and thus to render the oil so purified capable of being combined with the oils of fish, animals, grains, or other substances. *Patent abandoned.*

606. T. H. MORRELL and J. WILLIAMSON. *A new or improved method of purifying the noxious vapours or gases given off from night soil, or other similar substances, during the heating, drying, or evaporating of such substances.* Dated March 4, 1863.

This invention consists in drawing or forcing, or in drawing and forcing, the noxious vapours or gases given off from night soil, or other similar substances, during their heating, drying, or evaporation, or of otherwise conducting or passing such vapours or gases into or through chloride of lime, or any other similar purifying chemicals or purifying agents, strewed upon a series of perforated plates or bars, placed in the draught, or otherwise, in conjunction or connection with the oven or apparatus that may be used for evaporating the night soil or other similar substance. By these means night soil, or other such similar substances, may be readily prepared for use as a manure for agricultural purposes. *Patent completed.*

607. E. A. WUNSCH. *Improvements in treating sea-weed, and in apparatus therefor.* Dated March 4, 1863.

By the present invention, the sea-weed itself is made to supply a large portion of the heat required for the drying operation. For this purpose the patentee adopts furnace arrangements somewhat similar to what have been proposed

for burning "begasse," and other kinds of wet fuel. The invention cannot be described without reference to the drawings. *Patent completed.*

608. P. Adie. *Improvements in means and apparatus for measuring angular and actual distances.* Dated March 4, 1863.

These improvements relate to the arranging of the instruments patented by the present patentee 10th February (No. 357), 1860, in such a way as to get rid of the errors of eccentric and other parallax. For this purpose, in the first arrangement applied to measuring angular distances, he adopts two similar telescope object ends, one above the limb and the other below, the lower one being fixed to the limb, and the upper one with a vernier attached reading full degrees, and travelling over the length of the arc. To connect these the upper telescope has a hollow male centre at right angles to and in one piece with itself, and the lower one a female centre, also in one piece with and at right angles to the lower telescope. At the junctions of the male and female centres and their respective telescope tubes is placed a reflecting prism or other reflector in each, which sends the rays received from their respective object glasses through the hollow centre and towards each other; these rays are then received on two smaller reflectors mounted on an adjustable arm to correct for eccentricity and parallelism, each reflector occupying half the field of the eye-glass which then receives the rays. A position is given to the eye piece always intermediate to the angle of the two telescopes by means of two levers, each attached at one end to the object ends of the telescopes, and at the other end to a sliding piece on the eye tube, and turns on a centre round the outside of the female or lower telescope centre, and to this the interior or half prisms are attached with their adjustments. By this means, having the two telescopes and their reflectors symmetrical, he gets rid of all parallax, and gets parallel rays into the eye piece. The improvements may be applied, also, when only plain sights are used. He also adapts a small reflector, fixed to the eye tube centre, and brought by an arm over the centre of the instrument; this he uses as a finder and as a quick measurer of the angle, both arrangements reading in full degrees on the limb. The improvements relate—2, to the arranging of the reflectors in the second part of the invention, when the actual distance of an object is measured by the angle formed by the cones of rays of the two telescopes, so as to get rid of parallax, and bring the rays from both object-glasses parallel into one eye piece. For this purpose he attaches the object-glass of the moveable telescope, and the reflector behind it, to the inner tube, at the end farthest from the centre, the reflector behind the other object-glass, and the object-glass itself, being made a fixture to the outer tube. The centre round which the interior telescope turns he places near or in the middle of the instrument. The rays from both object-glasses, passed towards the centre by the above reflectors, are then received by two half reflectors, either one before the other, or their ends opposite to one another, when used in a hollow centre. For facilitating the fixing and adjustment of these prisms, he attaches the front one to the outside of the outer tube; or, if both are used in a hollow centre, he fixes both from the outside. *Patent completed.*

609. E. W. Binney. *Improvements in pressure and pump lamps.* (A communication.) March 4, 1863.

Provisional protection has not been granted for this invention.

610. E. W. Binney. *An improved lamp burner.* (A communication.) Dated March 4, 1863.

This invention relates to an improvement in attaching the cone or deflector to the burner of a lamp by means of a pivot, so as to allow the cone or deflector to work freely on this pivot in a horizontal direction, whereby the cone or deflector and draft chimney may be readily turned aside, or off from the burner, so as to expose the wick tube, and thereby render the wick accessible for trimming and lighting. *Patent abandoned.*

611. W. Clark. *Improvements in the manufactnre of sulphuric acid, and in apparatus for the same.* (A communication.) Dated March 4, 1863.

According to this invention, the inventor dispenses entirely with the use of leaden vessels in the manufacture of sulphuric acid. Although he dispenses with lead chambers, this improved apparatus presents a large surface to the gas, and so permits of its action on one and the other with the same facility as with lead chambers. These improvements are based on the principle that the combination of gases or vapours may be easily effected under the influence and through the intermediation of porous bodies. The substance employed for multiplying the points of contact of the gas, and presenting a large surface by its porosity in a small volume, consists of coke, which is well washed and calcined, the apparatus being formed of earthenware, and of peculiar form. The production of the sulphuric acid is effected in the ordinary manner—that is to say, by the combustion either of sulphur or of iron or copper pyrites. The invention cannot be described without reference to the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 5, 1863.

1401. A. Q. de Gromard, Paris, gentleman. Improvements in musical instruments.

Dated June 25, 1863.

1605. H. C. Lee, Lawrence Pountney-lane, merchant. Improvements in the construction of sewing machines. (A communication.)

Dated August 4, 1863.

1924. E. A. Cotelle, 29, Boulevart St. Martin, Paris, distiller. A new method of manufacturing gas alcohol by means of diluted acids acting indefinitely without reconcentration.

Dated August 12, 1863.

1989. L. R. Bodmer, 2, Thavies'-inn. An improved mode, and apparatus for, dressing and finishing and for imparting lustre to yarn and thread made of silk, cotton, and other fibrous substances. (A communication.)

1995. R. S. Newall, Gateshead. Improvements in apparatus for serving ropes for ships' rigging and other purposes.

Dated August 13, 1863.

1998. C. C. Dennett, Nottingham, builder. An improved method of fire-proof construction for buildings by the use of arches formed of concrete.

Dated August 15, 1863.

2030. J. Grantham, 31, Nicholas-lane, civil engineer. Improvements in apparatus for manufacturing salt.

Dated August 24, 1863.

2091. H. Batt, 21, Charlton, King's-road, Kentish-town. Improvements in roughing horses without taking off the shoe.

2096. F. R. Stack, Belgrave-villa, Finchley. Improvements in the construction of military bridges, piers, landing stages, and escalading apparatus.

Dated August 27, 1863.

2121. G. Richards, 2, Caroline-street, Bedford-square, esquire. Improvements in the construction of ordnance and firearms, and in the projectiles to be used therewith.

Dated August 28, 1863.

2127. L. A. Mulet, Rue St. Charles, No. 1, Thernes, Paris, merchant. An improved method of shoeing horses, and covering the feet or hoofs of other domestic animals with hardened india rubber, gutta percha, and other improved similar materials.

Dated August 29, 1863.

2137. W. Whitworth, engineer, and J. Wrigley, Sowerby Bridge, near Halifax. Improvements in, or applicable to, the furnaces of steam boilers.

Dated September 2, 1863.

2169. R. Sims, Bedford Foundry, Leigh, agricultural implement maker and iron founders. Improvement in reaping and mowing machines.

Dated September 3, 1863.

2174. A. L. Durand, 10, Rue de la Fidélité, Paris, merchant. Certain improvements in the manufacture of nails and other similar articles.

Dated September 4, 1863.

2183. C. Thornhill, Sheffield, merchant. A new or improved method of adapting steel or other suitable metallic wire to be used instead of animal bristles or hair, in sewing boots, shoes, saddlery, and leather works generally.

2184. C. G. Kelvey, Rock Ferry, Chester, watch manufacturer, and W. Holland, manager. Improvements in the construction of chronometers and other time-keepers.

2185. J. Hendry and W. Coutts, Aberdeen, merchants. Improvements in furnaces.

Dated September 7, 1863.

2198. J. B. York, Coleshill, gentleman. Improvements in privies or closets to be used in place of water-closets.

Dated September 8, 1863.

2211. J. D. Jack, Montrose, engineer. Improvements in moulding or shaping metals.

Dated September 9, 1863.

2214. J. Lille, civil engineer, and J. H. White, dentist, Manchester. An improved composition or coating for the protection and preservation of surfaces of iron, wood, and other materials.

2215. W. H. Hawksworth, Oldham, machinist. Certain improvements in apparatus for preparing cotton and other fibrous materials for spinning.

Dated September 10, 1863.

2229. J. H. Wilson, Liverpool, brass founder and ships' ironmonger. Improvements in side-lights for ships and other navigable vessels, and in the manufacture of the same.

Dated September 14, 1863.

2253. H. Riviere, 19, Queen's-road, Bayswater, gun maker. Improvements in the construction and application of apparatus and implements used for the purposes of heating, cooling, and evaporating.

2256. W. E. Gedge, 11, Wellington-street, Strand. Improvements in safety lamps for mines. (A communication.)

Dated September 16, 1863.

2264. J. Fox, Derby, engineer. Improvements in machinery for planing or cutting off the sides of armour plates.

2265. A. Fleming, Glasgow, mat maker. Improvements in cutting or finishing matting and similar fabrics, and in the machinery used therefor.

2266. G. Lewal, 5 and 6, Philpot-lane, engineer. An improved method of, and apparatus for, consuming smoke and heating and warming public and other buildings, and for drying purposes generally.

Dated September 17, 1863.

2277. J. McEwen, Lay's Foundry, near Brierly-hill, iron founder and coke manufacturer. A new or improved combined coke oven and hot blast oven or apparatus.

2278. Z. J. Mercier, 50, Rue de Longchamp, Chaillot, Paris, mechanician. An improved gas cock of elastic and continuous pressure.

2279. W. E. Gedge, 11, Wellington-street, Strand. Improved instruments for ascertaining levels, also for computing angles. (A communication.)

2281. A. Chaplin, 24, Cheyne-walk, Chelsea, engineer. Improvements in apparatus for propelling ships or vessels.

2282. P. Cowan, Barnes, manufacturer. An improvement in refining sugar.

2283. F. de Wyldé, Trinity-square, Tower-hill, gentleman. Improvements in the manufacture of an hydrated silica.

2284. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in taps. (A communication.)

2286. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in life belts and swimming belts. (A communication.)

2287. P. McLaurin, Glasgow, manufacturer. Improvements in drying paper, pasteboard, and similar fabrics, and in the machinery, apparatus, or means employed therein.

2289. J. Whitehead, Calverley, near Leeds, mechanic. Improvements in pneumatic motive power machinery.

Dated September 18, 1863.

2290. J. Allen, Manchester, engineer and brass founder. Improvements in the construction of valves and cocks for steam, water, gas, and other fluids.

2291. J. Roberts, Manchester, organ builder, and R. Naylor, gentleman. Improvements in increasing, diminishing, or otherwise regulating the power and tone of organs, harmoniums, pianofortes, or other instruments with similar keys or keyboards.

2292. R. D. Dwyer, Warrington, engineer. Improved apparatus for cleaning and painting or coating the bottoms of ships and other structures.

2293. G. Davies, 1, Serle-street, Lincoln's-inn, civil engineer. Improvements in the manufacture of iron and steel, and in apparatus to be employed in such manufacture. (A communication.)

2294. W. Lorberg, Wyld's-rents, Bermondsey, analytical chemist. Improvements in the treatment of rags, and obtaining valuable chemical products from the animal fibre therein.

2295. I. Baggs, Cambridge-terrace, electrician. Improvements in the means of protecting and preserving the hulls and bottoms of ships and vessels from fouling and corrosion.

2296. A. Noirot, 61, Rue Pigaile, Paris. New tiles.

2297. J. M. Cook, Leicester, hay and corn factor. Improvements in railway carriages and all other springed vehicles.

2298. R. A. Brooman, 166, Fleet-street, patent agent. An improved thread for fishing nets. (A communication.)

2299. H. W. Hart, Fleet-street, manufacturer. An improvement in T-fastenings.

2301. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improvement in propelling vessels, and in apparatus relating thereto. (A communication.)

2302. W. Smith, 19, Salisbury-street, Strand, civil engineer. Improvements in constructing breech-loading ordnance. (A communication.)

2303. W. Smith, 19, Salisbury-street, Strand, civil engineer. Improvements in the construction and mode of working ordnance for ships and forts, and in the means of protecting those engaged in working guns employed for such purposes. (A communication.)

2304. T. Small, Bargate, Boston, Lincolnshire. Improvements in motive-power machinery.

2305. V. Houghton, Grove-house, West Reading. Improvements in lamp and lamp wicks. (A communication.)

Dated September 19, 1863.

2307. J. Buckley, Lees, Yorkshire, manager. Certain improvements in mules for spinning cotton and other fibrous substances.

2309. R. Couchman, Noble-street, St. Martin's-le-Grand, manufacturer. Improvements in articles or instruments for supporting, holding, or carrying parasols, bags, watches, ornaments, or other articles or appendages.

2310. C. L. Fleischmann, 18, Rue Moncey, Paris. Improvements in machinery or apparatus for ginning cotton, also for cleaning, opening, and preparing cotton, wool, or other fibrous substances.

2311. B. Davis, Brettle-lane, Stafford, millwright, and W. Bowler, Wall-heath, Stafford, ironfounder. An improved mode of strengthening tilt hammers.

2312. J. C. Pooley, George-street, Bath, Somersetshire, chemist. Improvements in brewing or preparing beverages from malt and hops.

2313. J. P. B. Le Paturel, Piette-house, Guernsey. Improvements in breech-loading firearms.

2315. T. Richardson, Newcastle-upon-Tyne, chemist, J. Lundy, Leith, colour manufacturer, and R. Irvine, Magdalen Chemical Works, manufacturing chemist. Improvements in the extraction or manufacture of oils from vegetable substances.

2316. H. Bateman, Castlenau, Barnes, surveyor. An improved construction of rotary engine.

2317. T. E. Vickers, Sheffield, steel manufacturer. An improvement in the manufacture of cast-steel tyres. (A communication.)

Dated September 21, 1863.

2319. E. F. Battier, 82, Boulevart Sebastopol, Paris. Improvements in crinolines.

2321. W. B. Robins, Harborne, Staffordshire, actuary. Improvements in portable fire and garden engines.

2322. A. A. Downes, Stonnall, Staffordshire, spinster. Improvements in artificial teeth.

2323. E. Alcan, King-street, merchant. Improvements in shears for cutting metal threads, wires, and rods, applicable also for gauging wires. (A communication.)

2324. E. Alcan, King-street, merchant. Improvements in condensers, applicable to wool carding engines. (A communication.)

2325. F. A. Chåtel, 29, Boulevart St. Martin, Paris, manufacturer. Improvements in burners for burning all mineral oils. (Partly a communication.)

2326. R. Wallis, Basingstoke, Hants, corn and coal merchant. Improvements in apparatus for loading and unloading vessels, and raising, lowering, and otherwise conveying sacks, casks, agricultural produce, and other objects from one locality to another.

2327. R. Ridley, Leeds, and J. G. Jones, Cumming-street, Pentonville. Improvements in apparatus for giving a reciprocating motion to picks and cutting tools used in getting coal and other minerals and stone.

2328. G. T. Bousfield, Loughborough Park, Brixton. Improvements in power looms for weaving hair cloth and fabrics in which the weft is inserted in separate lengths of material. (A communication.)

2330. W. Hutchinson, 26, Rue Notre Dame des Victoires, Paris, manufacturer. Improvements in machinery for manufacturing moulded articles of india rubber. (A communication.)

2331. T. B. Daft, Harlesden. Improvements in the construction of ships and vessels, and in sheathing the same.

2332. W. A. Von Kanig, Bedford-place, Russell-square. Improvements in railway telegraphs and signals, and also in the permanent way and carriages, for preventing railway accidents.

Dated September 22, 1863.

2333. J. Renshaw and J. Haworth, Manchester, machinists. Improvements in machinery for stretching woven fabrics.

2335. P. Effertz, Manchester, engineer. Improvements in machinery or apparatus for making bricks, tiles, pipes, and other similar articles.

2336. C. Maitland, Alloa, brewer. Improvements in mashing apparatus.

2337. J. and J. Bond, Longridge, near Preston, machinists. Improvements in brick and tile-making machinery, applicable also to machinery for manufacturing other articles from plastic materials.

2339. J. Brigham and R. Bickerton, Berwick-on-Tweed, implement makers. Improvements in reaping or mowing machines.

Dated September 23, 1863.

2340. W. Clenimson, Ashton-under-Lyne, gas fitter. Improvements in the construction of pipe wrenches.

2341. J. Platt, 33, Argyle-street, St. Pancras, engineer. Improvements in machinery applicable to steam and water engines (as motors), which machinery is also applicable to lift and force pumps.

2343. W. and J. Galloway, Manchester, engineers. Improvements in lubricating journals of revolving shafts and axles, and in the apparatus employed for that purpose.

2344. E. T. Hughes, 123, Chancery-lane. Improvements in gas condensers. (A communication.)

2345. W. Gibb, spinner and manufacturer, and J. Holland, manager, Eccles, Lancashire. Improvements in looms for weaving.

2346. W. T. Eley, Gray's-inn-road. Improvements in the manufacture or construction of ball cartridges.

2347. A. Collingridge, 82, Cheapside. Improvements in the manufacture of casks and other receptacles for containing oil, petroleum, and other liquids.

2348. J. Phillips, Tollington-road, Holloway, civil engineer. Improvements in the construction of levels, applicable to levelling, surveying, astronomical, nautical, and other instruments or purposes to which levels are applicable.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, October 6, 1863.

1279. J. Fawcett. Preparation of food for cattle, horses, and other animals.

1287. G. Stevens. Coke ovens.

1342. T. Richardson and R. Irvine. Preparation of Esparto grass.

1346. R. A. Brooman. Paddle wheels. (A communication.)

1347. W. Needham and J. Kite. Expressing liquid and moisture.

1351. J. J. Potel. Accelerating the draft in furnaces and fire-places.

1356. F. Patureau. Cardboard or paper boxes or receptacles.

1366. F. W. Smith. Conveying goods either in bulk or otherwise.

1377. G. A. and A. Barrett, W. Exall, and C. J. Andrewes. Regulating the speed of steam engines. (Partly a communication.)

1387. G. Davies. "Ginning" cotton. (A communication.)

1403. T. Gray. Treating substances.

1415. W. Clark. Mounting and fitting bedsteads, chairs, and other moveable seats on board ship. (A communication.)

1422. R. C. Furley. Preparation of castor and other oils for medicinal use.

1423. H. Reynell. Manufacture (by the introduction of cocoa-nut husk or part thereof) of a substitute for ordinary felt and kamptulicon.

1426. J. Petrie. Washing wool.

1431. C. Nicquet. Sorting and washing ores.

1499. W. Clark. Engines for obtaining motive power from steam or other liquid. (A communication.)

1522. A Samuelson. Evaporating liquids.

1568. W. Toovey. Photo-lithography, photo-zincography, and photographic engraving.

1597. A. Ripley. Method and construction of a packing chiefly applicable to piston rods, pumps, and such like, and forming the joints of gas, steam, or water pipes.

1762. W. Wood. "Warping" or covering land, bog, or peat, with earth or soil.

1824. C. S. Duncan. Means of, and apparatus for, heating, melting, boiling, evaporating, and other useful purposes.

1880. H. A. Bonneville. Self-acting flushing apparatus. (A communication.)

1923. J. H. Walsh. Breech-loading firearms.

1998. C. C. Dennett. Fire-proof construction for buildings.

2014. H. H. Lishman. Punching and marking plates in which holes are to be punched.

2142. A. Rowand. Evaporating fluid solutions.

2188. G. Hargreaves. Steam boilers.

2337. J. and J. Bond. Brick and tile making machinery.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed October 2, 1863.

864. F. C. Bakewell.
865. B. Cooper.
870. J. Burwin.
872. J. Swinburne and J. Stanley.

STEAM SHIP ECONOMY.

Few steam ships can carry coals sufficient for more than a ten days' trip; and the fact certainly does not strengthen a belief in the engineering progress of the twenty years or so which have elapsed since the steam engine was fairly set afloat on a commercial footing. The "British Queen" or the "Great Western" could have kept the sea for as long a period as most of the steam ships, of a similar size and class, built recently; and, with all our boasted finish and workmanship, it is doubtful if the marine engines of the present day answer their purpose a whit better than those constructed during the noviciate of firms which have now attained to very high positions. One unfamiliar with the past history of the steam engine, made acquainted for the first time with the fact contained in the first lines of this article, would naturally ask in what respect are the engines of our Navy or our mercantile fleets, superior to those built the fourth part of a century since? Truth answers, in nothing save a slight reduction in size and weight. A little less money is expended in repairs, the consumption of oil and tallow is perhaps reduced, the weights and strains of the engines, are better distributed through the hull and ship, and machinery possibly lasts a little longer; but these are trifling considerations in the face of an increased first-cost, and a consumption of fuel at least twice as great as it should be; all the skill and energy of the period which has elapsed since the "Royal William" first demonstrated the practicability of voyage under steam across the Atlantic, having failed to reduce it by much more than a pound or two per horse-power per hour. The explanation of all this is very simple, and possibly from that reason very much overlooked. The principles involved in the working operations of the modern engine are precisely the same as those which gave vitatity, so to speak, to its predecessor. Changes in form are met with ordinarily enough; but the economy of fuel depends very slightly, if at all, on shape or its varieties, so long as there is no grievous departure from those forms which practice has proved moderately correct. The same quantities of fuel will give like results, whether the steam is worked in a vertical, horizontal, or oscillating cylinder. It is not in principles of construction, but in those of working, that radical changes are necessary, before we can hope for well-defined improvement.

The coal bill of our Navy is a serious item in the national expenditure—one so serious, indeed, that those who pay it are entitled to demand its reduction to the lowest possible limit which the legitimate service of the State will permit. Still, while we see a reckless expenditure adhered to by private steam ship companies, it may be urged that it is unfair to expect that Government should bestir itself very vigorously to bring about a reduction in the rate of exhaustion of our coal fields. Reflexion will show, however, that this argument is of little weight, inasmuch as all the large steam companies virtually have the greater proportion, if not the entire amount, of their expenditure for coals repaid by Government subsidy, without which they could not exist as corporate bodies; and it is a highly suggestive fact, that to single ships, belonging to private individuals or firms, we can alone look for the realization of any economical results. Many such vessels are paying their way well—in the Mediterranean, for example—with a consumption of not over $2\frac{1}{2}$ lbs. of coal per indicated horse-power per hour. Competition is so powerful, that a very slight increase in the working expenses of a steam ship line, may render that which would otherwise be a successful commercial undertaking, an utter failure. We do not dispute that those mechanical expedients, which prove useful to non-subsidized lines, are equally applicable to those which must rely on their own resources. The most influential steam companies have, however, hitherto refused to adopt them, principally because they are content with the results achieved, and do not care to risk their subsidy by the chance of breaking their contract by the failure of engines embracing novelties. Thus, the "Scotia" is fitted with engines which would half ruin a company not receiving Government aid. Subsidies cover a multitude of engineering sins; and we feel little doubt that, had they never existed as an institution, marine engineering would be much further advanced than it is.

It is urged that marine engines which are economical in the consumption of fuel, are complicated, and liable to get out of order, requiring the expenditure of much money on repairs. We confess we are unable to see the cogency of this style of argument. The wear and tear of boilers must naturally depend almost altogether on the quantity of fuel burned in them, and the conditions regulating its combustion. If one steam ship requires four boilers to perform the work accomplished by another with two, it is easy to see that, the same rate of combustion being observed on the grates, the boiler expenses must be just twice as great in the former as in the latter case; while the engines, if constructed on correct principles, cannot suffer more in one case then the other, provided the same amount of work is developed in their cylinders, and transmitted through the parts in motion. Certain forms of engine and boiler have been proposed and patented, made and set to work, in which everything was sacrificed to high pressure. The result has been failure, as might reasonably have been expected. Much injury has been done to the science of marine engineering by rash impetuosity; but it speaks poorly for our constructive enterprise, if a few such failures should prove more effectual in staying our onward progress, than a hundred successes in hastening it.

It is much to be deplored that the advocates of steam ship economy should have insisted so strenuously on the employment of excessive pressures. Theoretically right, these gentlemen have failed to see that the means essential to the carrying out of their principles, were practically wrong under the exigencies of maritime service. The ordinary type of marine boiler is quite unfit for carrying anything like high steam; yet its external form is dictated by the shape of the space devoted to it within the hull. Long experience has proved such boilers to be perfectly trustworthy up to pressures of 25 lbs. to the inch; Messrs. Maudslay and Field proving their boilers, for instance, to 75 lbs. on the square inch before they leave the works. The attempt to displace these with generators—novel in all their features, and intended to carry as much as 100 lbs. on the inch—has resulted, as might be expected, in failures. We believe that such pressures are admirably adapted, when combined with expansion, to promote economy of fuel; but it is next to impossible to construct a thoroughly good marine boiler which will carry them, without priming, boiling dry, leaking, or generally doing that which it should not. A certain space is devoted in every steam ship to the boilers, and a certain space to the stokehole; and the boilers must be so designed, that all repairs involving the handling of long tubes, &c., can be performed from this last. Thus, the lengths of the ordinary tube flues are either regulated by, or regulate, the width of the firing space; as otherwise, they could neither be removed, nor replaced when occasion required. For this reason, a boiler could not be repaired, under ordinary conditions, in which the flues ran at right angles to the direction in which they are now placed. From this we may learn why so many high-pressure marine boilers have failed to meet with adoption. They have been designed without any regard to these considerations; and although they might have proved perfectly successful on land, where there was ample room to gain access to every part of them, they have been unsuccessful at sea, because they could not receive substantial repairs without lifting them out of the hull.

It is quite certain that, while we retain pressures of 20 lbs. or 25 lbs. to the in., we shall never reduce the consumption of fuel in any material degree; and it is equally true that, with the rectangular boiler in ordinary use we cannot carry any pressure much higher. We may consider the complicated boiler question pretty well at rest, for the present at least; and we feel no hesitation in pointing out the cylindrical fire-box boiler as the best for the marine engine, as it has been for the locomotive. The working necessities of these generators, and the rules regulating their construction and proportion, are, perhaps, better understood than anything else connected with the steam engine, while their performance and durability is everything that can be required by the most fastidious. The only question remaining for solution is their adaptability to the space which can be afforded them on board ship. Under its present form the locomotive boiler is, doubtless, inadmissible; one of the strongest objections being, that for reasons already pointed out, flues could neither be cleaned nor replaced. A tubular boiler of the kind, however, made flush with the fire-box, and 5 ft. in diameter, would easily carry 60 lbs. of steam per square inch, while the flue tubes could be replaced through the fire-box. Six or seven feet is the usual length of the tubes in an ordinary marine boiler, the grates being generally a little longer. A cylindrical boiler might be constructed with a 7 ft. grate, and tubes 6 ft. 9 in. long, from which, by using a large number of tubes of small diameter, very good economical results might be attained. Arranged fore and aft, side by side, three or four such boilers would occupy very little more space in the length and breadth of the ship than that taken up by those of the ordinary class; while the space above them could be advantageously employed as a coal bunker if the ship was a small one.

It is sufficiently strange that all the attempts hitherto made at the introduction of economical marine engines have entailed the use of enormously heavy machinery. The prejudice against high piston speed, is, or rather has been, so universal, that light quick-actioned engines have never had a fair trial. Very large pistons cannot be employed with high-pressure steam, in consequence of the injurious shock which it produces when acting on a large surface at the commencement of a stroke. Double-cylinder engines, in which the steam acts first in a small cylinder, expanding thence into a larger one, have been thus rendered indispensable. Such engines are unavoidably heavy and expensive, to say nothing

of the great space which they take up in the hull. This kind of machinery never can come into general favour with private companies, whatever it may do with the Government. Nor is it necessary that it should. A certain amount of area should be divided among a number of small pistons, not concentrated in one or two larger ones. By doubling the speed at which pistons are driven at present, that area may be reduced one-half, and the shock of steam of 60 lbs. or 70 lbs. to the inch need no longer be dreaded. Steam should give out its useful effect in the same cylinder which it first entered, as the injurious results which attend its flow through long ports and passages are thus avoided, while the valve gear is simplified, and minor matters of detail more easily worked out. Apart from these considerations, we may remark that, engine framing generally is much too heavy: mere weight never secures strength, but, on the contrary, tends to strain every rib and frame connected with the engine.

Our Government have expended, within a very few years, over two millions and a half of money on a series of costly gunnery experiments which have resulted in no practical good. We venture to say that had one half the sum been expended on the improvement of the engines intended to propel our war ships, it would have produced results of the greatest value to the nation. The most powerful ordnance ever constructed becomes valueless if placed on board vessels which can neither steam fast, nor yet keep the sea more than a few days at a time. We feel little doubt that the day is not far distant when masts and sails will be regarded in the same light in the Navy as they are in the mercantile steam marine—that is, as incompatible, when of full size, with high speed. Our Navy should rely on its engines almost wholly. Until it does, our best ships must remain comparatively slow under steam, and still slower under sails, and will, we fear, be found wanting in a warfare in which success will surely wait on speed.

SUBMARINE CABLES.

The practicability of ocean telegraphy is once again to be tested on a considerable scale. Four undertakings of this description—two being enterprises of world-wide importance—are in various stages of progress, and will, it is hoped, become established facts in the course of the approaching year. By their success or failure, the progress of this branch of science will very probably be influenced very materially. We propose, therefore, to glance at the means about to be adopted for carrying out each of them.

The French line may be first mentioned. This cable has been undertaken for the Imperial Government by Messrs. Siemens, Halske, and Co., and is shortly to be laid between Oran, in Algiers, and Carthagena, in Spain—a distance of some 250 miles; the communication being continued from the latter place by means of land wires through the Spanish territory into France. The cable is on the plan which has been patented by Messrs. Siemens and Co., and of which specimens were shown in the Exhibition of 1862—with the exception that the insulation of the present cable is entirely of gutta percha, instead of part gutta percha and part india rubber, as originally recommended by the inventors. The conductor is a strand of 3 No. 22 copper wires laid together spirally; and the diameter of the core, consisting of the insulator and the conductor, is about 3-10ths of an inch—this is surrounded by a pad consisting of a double layer of hemp strings running spirally in opposite directions. Around these hempen strings is laid the final metallic sheath, which is made of phosphuretted copper rolled into ribbon about a quarter of an inch in breadth and the 20th of an inch in thickness. The ribbon so made is laid in a short spiral, every turn overlapping the one preceding it after the fashion of ancient scale armour. The diameter of the entire cable does not exceed 4-10ths of an inch, and the specific gravity is low; but the policy of employing so small a conductor, and an insulation so slight, may fairly be doubted, as also may the weakness of the completed cable under strain.

A more extensive undertaking than this will be the cable now in course of shipment by Mr. W. T. Henley, of North Woolwich, for the Indian Government, and the laying of which has been entrusted to Messrs. Bright and Clark, under whose specification and superintendence, it has been manufactured by Mr. Henley. The core consists of a copper conductor, which, though presenting a solid appearance, consists, in fact, of several segments drawn out together and firmly encased in a surrounding tube. This arrangement is supposed to secure all the advantages to be derived from solid copper, without the danger of internal and unperceived fracture of the conductor, on account of its liability to which, that form of the latter has long been laid aside in favour of conductors worked into a strand. A conductor so constructed may escape severance in shallow water, like that of the Persian Gulf; but for deep sea cables, a conductor of that class would be a very dangerous experiment.

The conductor of the Persian Gulf line weighs 225 lbs. to the nautical mile, and is surrounded by 275 lbs. of gutta percha per mile for its insulation. The core thus formed is padded with a spiral ribbon of hemp saturated in tar-mixture, the hemp in turn being surrounded spirally by 10 No. 7 iron wires. Finally, the entire cable so constructed, is lapped with yarn over its external circumference and served with a composition of pitch, tar, and silica, laid on at a heat of 300 deg. Fahr., for the purpose of preserving the outer iron wires from oxidation. The cable is to be taken out to the Persian Gulf in five vessels, three of which have already started on their way to that rendezvous. One, however, the "Assaye," has been driven into Plymouth, where she still remains, by stress of weather. They are sailing vessels; and it is intended to tow them by means of steamers during the paying out, the depth being scarcely anywhere more than 50 fathoms. The cable will be laid in several sections, commencing at Bussora at the head of the Gulf, and completing the work at Gwaddell, on the coast of Belochistan, whence the wires are continued to Kurrachee, Bombay, and the most important centres in India. The length of this cable is over 1,200 nautical miles.

The third cable is a sort of adjunct to the last mentioned, and will be similar in construction. Its importance consists in the fact, that it forms a link of about 60 miles in the communication with the East, which it connects with the direct European lines going west and north from the coast of Italy.

But the circumstance to which the chief importance attaches in the present history of submarine telegraphs, is the resuscitation of the original Atlantic Telegraph Company. They have now provided the means for purchasing a new cable, and the attempt will be made to restore communication with America during the summer of 1864. On the present occasion, the Board have committed their scientific affairs and the judgment of the tenders sent in reply to their advertisement, to a Scientific Committee, composed of Mr. William Fairbairn, Mr. Joseph Whitworth, Captain Douglas Galton, Professor Wheatstone, and Professor William Thomson.

These gentlemen decided in favour of Glass, Elliot, and Company's offer, but required, as regards the external armour of the cable, that they themselves should institute certain experiments and finally determine how it was to be constructed.

As regards the core, it has been generally conceded that the one fixed on is suitable. It will be made up of a conductor having seven wires laid spirally into a strand containing 300 lbs. of copper to the nautical mile. The insulator will be of gutta percha, laid on in four layers, alternately with four layers of Chatterton's compound. The entire insulator weighs 400lbs., and the entire core 700lbs. per knot.

As to the external covering, the problem new being worked out at Greenwich, and at the works of Messrs. Fairbairn, is to obtain for the whole cable completed, a specific gravity, of about 1·8, with a breaking strain of about 9 tons, giving thereby a cable capable of bearing about 13 miles of its own length perpendicularly suspended in water.

As the greatest depth of the route between Newfoundland and Ireland is only 2½ miles, it is thought that this will leave an ample margin; and as it is stated that a cable of this description can be constructed by means of a combination of hemp and the best charcoal or homogeneous iron without any unattainable increase of expense, it is most probable that these materials, in proportions now being ascertained by actual experiment, will constitute the external coat of the future Atlantic cable.

So sanguine are the contractors of being able to succeed in this great work, that they have materially increased their pecuniary interest in the share capital of the Company since the contract has been awarded to them.

Glass, Elliot, and Company, have undertaken the entire work of manufacturing and laying the cable, and are to hand over the communication to the directors in perfect order during the summer or autumn of 1864; their profit of 20 per cent. being payable in twelve monthly instalments (to cease if the cable is imperfect), commencing immediately the cable is in efficient working order.

LARGE DRIVING WHEELS FOR LOCOMOTIVES.

Few things have been more over-estimated than the importance of high driving wheels for express engines. We may, perhaps, trace back the origin of the idea to Brunel, who designed and caused to be built more than one locomotive with 10 ft. driving wheels, and but 475 square feet of heating surface, or thereabouts. Need we say that these engines were total failures. What between their small power of making steam, and the size and weight of their wheels, they were almost unmanageable, and brought large drivers into disgrace for a time. The very infancy of the railway system, however, was distinguished by an intense desire on the part of most engineers for the attainment of speeds, which we, even with our superior facilities for construction, regard as excessive. The principles governing the action of steam were not understood then as well as now; and from fancied difficulties connected with its passage to and from the cylinders, a slow reciprocation of the piston was deemed worth having at any sacrifice. Larger and larger wheels were therefore adopted as soon as the reaction succeeding Brunel's failure had set in, and

some years since we arrived at the very general employment of an 8-ft. wheel for express engines. High wheels were early adopted by American builders. In 1849, several engines were placed on the New York and Erie Railroad, with two pairs of 7-ft. drivers; the cylinders, 14 in. diameter, having the enormous stroke of 32 in. Eight-feet drivers are still used on the Camden and Amboy Railway; strangely enough, with goods engines. In France, Gouin and Co. built an engine, "l'Aigle," in 1854, with drivers 9 ft. 4 in. in diameter, with outside level cylinders 16½ in. in diameter, and 31½ in. stroke. Several engines with 8-ft. wheels may be met with on many of the French lines. Neither here nor elsewhere, however, do these great diameters gain in favour, except for exceptional locomotives of great size; and the engines which prove their superior efficiency by doing most work, seldom have drivers much over 6 ft. in diameter. Our friends at the other side of the Atlantic have been so thoroughly convinced, by practical experience, that the adoption of a large wheel is not only unnecessary, but positively injudicious, that the practice of "cropping" drivers was at one time almost universal; engines with 7-ft. and 8-ft. drivers having these removed, and replaced by wheels a foot or two less, with manifest advantage.

The size of a driver has really very little connection with the speed of an engine. There is no good reason whatever that a pair of pistons should not do their work as well, when moving at 1,100 ft. per minute as at half that speed. It is merely a question of wear and tear; and railway statistics prove that piston speed exercises little if any influence on expenses incurred for repairs. Indeed, it is not easy to see how it can. Some years ago, when locomotive construction was not so well understood as it is now, very considerable difficulty was experienced in keeping pistons fast on their rods. They worked loose continually, and every now and then smashed through a cylinder cover. But this occurred with the pistons of all sorts of locomotives, both slow and fast. Improved methods of valve setting, by providing a moderate amount of compression, quickly obviated the evil, and even had it not done so, we now understand how to forge the piston and rod in one piece, so as to render such a catastrophe impossible. We have ere now pointed out, that the pressure on the piston is no measure whatever of the strain on the crank pin, especially in quick-working engines. The proper combination of the expansion of the steam with the momentum of the reciprocating parts, enables us to equalize these strains, reducing the danger of fracture to a minimum. The engine, indeed, if properly balanced, may, from this reason alone, run with less danger of accident at a high speed than at a low one, provided the principle of expansion is properly carried out.

Engines, with high drivers, are notoriously bad at a dead pull. It is urged, indeed, that under any practicable load which we can place on a single pair of drivers, a 17½ in. piston acting on a 12-inch crank, with 120lbs. steam, will cause them to slip so long as they are under 10 ft. in diameter. We much doubt the truth of the assertion however, provided the rails are clean; and the engineers of express engines know but too well, what it is to struggle up an incline with a slightly abnormal load. The actual tractive power of an engine, with 4 ft. drivers is, *cæteris paribus*, just double that of one with wheels twice the diameter, and the former, will—speeds being the same—develop just half the horse-power of the latter per mile. It is a necessity, in fact, with the engine with high drivers, that it must run at speed to develop power with heavy loads; high wheels preclude speed; hence we find that express trains seldom weigh over 50 or 60 tons. Were smaller drivers employed, the same speeds could be attained, while inclines, or an extra carriage or two, would present none of the difficulties which they do now.

It is quite possible to overcome this want of tractive force by adopting large cylinders. We question, however, that a recourse to this expedient is advisable. Engineers are well aware that the dimensions of the cylinders are generally a measure of the size of the engine. Although they do not necessarily entail an increase in the capacity of the boiler, still large cylinders require stronger framing, larger valves, and heavier connecting rods, &c., than those of smaller diameter. These matters quickly swell the proportions of an engine to something very considerable; and we may, in consequence, determine without much hesitation, that weight in an efficient express locomotive is in direct proportion to the dimensions of the driving wheels. Now, it does not require a very profound knowledge of railway matters to demonstrate that small engines are invariably more efficient, proportionally, than large ones; and permanent way complains sadly of the usage which it meets with from engines with 12 tons on a single pair of driving wheels.

Speed really depends on boiler power, and the rapid reciprocation of the pistons is no real evil. Theoretically objectionable, practice proves, in the clearest manner, that working expenses are not increased by it to any appreciable extent. Immense driving wheels no longer enjoy the popularity they once did; and we much doubt that any engines are now being built with them. Indicator diagrams taken from an express engine, with 7 ft. 2 in. drivers, at a speed of 63 miles per hour, are almost identical with those taken from a nearly similar engine, with drivers a foot higher, at 60 miles per hour. The indicator is, after all, the real test of the good qualities of a locomotive, as far as the action of steam is concerned; and we regard such a result as pretty conclusive evidence that nothing is to be gained by the use of a wheel much over 6 ft. in diameter. A rapid reciprocation of the pistons permits the use of a large blast-pipe, as the blast in the chimney is equalized, and rendered more effective, while it does not cut up the fire so much as an exhaust at comparatively distant intervals. Regard the matter as we may, we believe that there is no difficulty in proving that the most efficient engines ever built have had driving wheels of moderate diameter; and railway companies will find it good policy to return to their use.

THE IRON TRADE OF BELGIUM.

THE following account of the Iron Trade of Belgium appears in the official report by Her Majesty's Secretary of Legation, at Brussels:—

Iron ore is found in abundance in every province of Belgium, but principally in Namur, Hainaut, Liege, and Luxembourg—the four mining provinces. That found in the five Northern Provinces is all so-called "alluvial" ore found on the surface, and not in subterranean mines. The following are the three main varieties of ore raised in Belgium.

Pyrites, a combination of sulphur and iron, long treated by the Custom-house solely as iron ore, and as such prohibited from export, by an erroneous interpretation of the tariff. It is now recognized to be worthless for its ferruginous constituents, but is much demanded, and exported in large quantities to France and England, for the purpose of making sulphuric acid.

Oligist ore is a red oxide of iron, generally impregnated with phosphorus in such large proportions as to yield a pig iron too brittle for refining purposes. It used to be quite neglected until M. Behr, the director of the Ongrée Iron Works, in conjunction with M. Montefiore Levi, discovered a means of utilizing it by mixing it in the furnace with a flux composed of carboniferous schist mixed with limestone. Thus oligist becomes available in the furnace in combination with yellow ore in the proportion of 60 per 100, and even alone. This Belgian invention has tended to reduce the price, and also the general quality of the metal. The prices of oligist ore vary from 6 to 15 francs per ton.

The third description is hydrated or yellow ore, and includes a great many varieties, of which the brown hematite is the best. Hydrated ore is only used for the best iron. Some rich seams of it are found in Belgium, especially at Athus, and Ruette in Luxembourg, and at Morialmé Fraire, Acoz, Ligny, Jamiolle, Tres Gomezée, Bois des Minières, and Courin, nearly all in the province of Namur. These are ores of the first quality, and give a yield of 40 per cent. in the furnace. This description of ore is still prohibited from export, excepting to France and the Grand Duchy of Luxembourg.

Since 1830, great anarchy has crept into the administration of the iron mines. The organic law of 1810 lays down the principles by which they are still nominally governed. All deposits of iron ores in subterranean veins or strata are by that law classified under the head of mines, and are not to be worked without a concession emanating from the Crown. All superficial or alluvial beds of ore are classified as "minières," and may be worked by the owner of the land, on simply serving a declaration to that effect on the provincial authorities. This legal distinction is now generally evaded. The great bulk of the iron produce is now raised from the so-called "free iron mines," *i.e.*, mines not legally conceded. Only 20 mines are provided with concessions; all the others, nearly 2,000 in number situated in 109 different communes of the four mining provinces alone, are tolerated to exist without restriction or taxation, under the name of "minières," though most of them are subterraneous. The number of these pits in 1855 was 1,208, and the labourers employed in them were 5,271; the number of communes was 64. As the number of communes having such mines has increased since then to 109, it may be presumed that the number of pits and hands employed has risen in a similar proportion. This irregularity has led to an improvident working, and even to the total destruction by water of valuable mines. Every landlord is allowed to carry on his works in his own way, subject to the control of the inspectors only for the prevention of accidents to the workmen or to the houses on the surface. Some law on this subject is urgently called for, as the tribunals refuse to execute the ancient law, and no new concessions can be granted.

The principality of Liege and the county of Namur were two of the earliest seats of the iron manufacture, and even claim the invention of the art of manipulating iron by means of coal, as also of the high-blast furnace for producing pig iron. The first of these is said to have been that of Marche-les-Dames, erected in 1340. The earliest furnaces on record were on the low Catalan principle, which yeilds at the first fusion malleable iron. The high-blast furnace and the art of casting were brought to great perfection at Liege as early as in the 16th century. Here, as in England, fruitless efforts were long made with a view of applying coal and coke to the production of crude iron. This great economical revolution was accomplished in England in 1730, but not till 1821 in Belgium.

One of the first coke-blast furnaces was established in 1823, at Seraing by Mr. John Cockerill. The extensive iron works at that place had been founded by him in 1817, with the assistance of the King. His Majesty even became a joint proprietor of them by purchasing, in 1825, the share belonging to Mr. Cockerill's brother. This factory was long without a rival on the Continent, both for its gigantic size and perfect internal economy. Mr. Cockerill showed no less genius in his financial than his mechanical combinations, and became one of the founders of the National Bank. Unfortunately, his restless spirit impelled him to embark in a great number (no less than sixty) of other enterprises in distant countries, even in Surinam. The Belgian Revolution was the first event that checked his career. The new Government claimed to succeed to the rights of King William, until Mr. Cockerill, by a great financial effort, made himself sole master of Seraing, and brought it to its highest pitch of prosperity in 1838. The National Bank having suspended payment in that year, Mr. Cockerill was

obliged to adopt the same course. He died in 1840, leaving an untarnished reputation as a liberal employer, a daring but honourable speculator, and a father of Belgian manufacturing industry. The Seraing works are now carried on by a flourishing "anonyme" company, under the name of "Société de John Cockerill," and still enjoy a European celebrity and custom. They include within the same area a coal mine, six blast furnaces, an iron factory provided with every apparatus, a steel puddling-mill, and machine factory.

Belgium possessed in 1820 about fifty iron blast-furnaces adapted for charcoal, and not one for coke. Since then a great number of the latter have sprung up in the coal-basins of Liege and Charleroy. Numerous refining and cupola furnaces, as well as puddling, rolling, hammering, splitting and wire mills, have been erected and provided with the best appliances. The wealth created by this metal alone was estimated at 81,000,000 francs in 1860, and the exports at 24,750,000 francs. Belgium does not possess, like Wales, beds of iron and coal overlying each other in the same mine, but possesses both minerals in close proximity to each other.

The number of smelting furnaces in blast has fallen from 66 in 1857 to 51 in 1860, only one more than in 1820; but these 51 being all, with 8 exceptions, adapted for coke, produced 319,913 tons of pig iron, valued at 26,500,000 francs, probably four times the amount of the earlier period. Still these figures show a great falling off since 1857. There is still a small quantity of charcoal-iron produced in the province of Namur, valued at 128 francs per ton, or 50 per cent. above the average of coke-iron. Not a single charcoal furnace remains in blast in Luxembourg, though this province is the richest in forests and in good ores. A short summary of the fluctuations of the iron trade will be afforded by the following Tables :—

Comparative Statement of the Iron Furnaces and other Metal Works in Blast, and of the number of Hands employed therein, during the following Years :—

	Factories.			Workmen.		
	1851.	1857.	1860.	1851.	1857.	1860.
Iron smelting furnaces	46	66	51	3,067	4,423	4,078

The enormous increase in the produce of iron has not taken place without some sacrifice of quality. Bars and rails of the present day are not what they were even ten years ago. Belgian irons compete closely with our own in quality and price. In the former respect, they are superior to our ordinary descriptions, which is attributed to the universal employment of coke in Belgian furnaces instead of coal, as is usual in England. The grey pig irons generally used in England are certainly superior to the white irons used in Belgium; but they require a larger amount of puddling than the high price of labour generally enables them to receive; so that when turned out in that imperfect state they are inferior to white irons for refining purposes. Belgian bars may on an average be classed below those of Yorkshire, especially those of Lowmoor, on a par with Staffordshire, and above Welsh irons. Belgian foundry iron has more tenacity, but less ductility, than the English article, owing to the use of coke.

Great improvements have been introduced in the manufacture of iron of late years, especially Calder's hot blast. A patent has been taken out by a Belgian engineer, M. Fromont, and generally introduced, whereby the hot blast can be intensified to a temperature of 500 deg. for making foundry iron. Some articles of wrought iron, such as wheel-tyres without joints, and fish-joint bolts, can be made in Belgium more cheaply than in England; so that a British firm which has lately taken an extensive contract in Holland has ordered these accessories in Belgium. In rails, none can undersell the Welsh, but the Belgians compete successfully with them, owing to differences of quality in foreign markets. Thus, at a recent extensive adjudication in the South of France, a Hainaut firm obtained a contract for 12,000 tons of rails at 20 francs per ton higher than a tender submitted by a Welsh house.

Belgian sheet iron, particularly the best quality, called "tôles fines de commerce," is much esteemed in and much exported to France. Split iron is little used in France, but is still produced in Belgium in large quantities for the nail-makers, who prefer it on account of its cheapness to rod iron. The nail manufacture is another Belgian staple, which has attained immense proportions: it offers the great advantage of being exercised in the workman's own house, at his own fireside, and even in his own kitchen fire; it is the winter employment of thousands, who in spring migrate to France to make bricks. Belgian nails are exported to all parts of the world.

The exports of machinery have increased from 4,750,000 francs in 1851 to 13,000,000 francs in 1861; still complaints are made of insufficient profits, owing to the constant fall of prices in the rolling-stock of railways. The French and German markets are completely closed against this branch of Belgian industry. The Russian demand is great and increasing. Italy, Spain, and Portugal take many locomotive engines annually. A fine specimen of this article, the work of the Couillet iron factory, was seen at the London Exhibition.

The history of the arms trade seems to be one of unbroken prosperity; the demand seems to be insatiable. The year 1860 already showed the largest export of small arms on record, but was surpassed in the proportion of 2 to 3 by its successor, which showed an export of 18,000,000 francs in value. All the muskets that could possibly be supplied have been hurried off to the United States, at a great pecuniary profit to Liege. This branch of industry has been also much benefited by orders for rifles executed for Her Majesty's Government; these arms are subjected to unusually severe trials, and have thus been the means of raising the standard of quality of the higher class of Liege small-arms. The wages of labour in this trade have risen to an unprecedented height; nevertheless, some skilled mechanics formerly engaged on fowling-pieces of high finish have been out of work, or have been obliged to learn to make muskets. The Liege arms manufacture is principally carried on by the men in their own houses. The numbers of firearms tested at the Liege "banc d'épreuves," exclusive of those manufactured at the Royal foundry, were, in 1859, 481,767; in 1860, 562,279.

The iron exports of all kinds have risen from 11,750,000 francs in 1851 to 25,000,000 francs in 1857 and 1860; the values for 1861 are not yet assessed, but the quantities show an increase on the whole, though a decrease in some articles, such as nails and rails. The export of pig iron has receded since 1857, owing to the increase of duty in the Zollverein; but that of ores and wrought iron has been and is constantly progressing. The year 1861 has been one of depression, but not of total stagnation; prices have fallen back to the ruinous figures of 1847, and the profits of the blast furnaces have been little or nothing. The iron factories have done rather better, and have been fully employed, though at low rates.

The Belgian ironmasters have shown themselves advocates of progress and free trade; they have declared themselves ready to meet English competition, though at present in possession of a virtual monopoly of the home trade. Some small quantities of Swedish pig iron, and of English wire, steel, and hardware are imported. Every effort is made by this powerful industry to force a sale of its produce abroad. Four of the great Hainaut firms, those of Couillet, Monceau, Chatelineau, and Thyle-Château, have combined to form an "Union Sidérurgique" for the purpose of maintaining joint agents in foreign countries to canvass for orders. The shares and profits of all these undertakings have fallen to a low ebb. The last quotations show a slight reaction in prices; the firmness of the English market is acting on that of Belgium.

ON IMPROVEMENTS IN MACHINERY AND APPARATUS FOR CLEANSING AND PURIFYING CASKS.*

By Robert Davison, C.E.

In the Paper which the author had the honour of reading before this Association in the year 1849, on the "Desiccating Process," he took occasion to mention its application, amongst others, to the purifying of brewers' casks, and further stated that upwards of one million casks had at that time undergone the process. It was not, however, made clear that the casks had to undergo a previous operation, namely, that of cleansing, which was effected by machines of peculiar construction, completely removing all adhering matter from the inside without resorting to the expensive and injurious system of unheading.

The object of the present Paper is not only to confirm all that was then stated as to the efficiency of the hot air system by stating that upwards of eleven millions of casks have since been treated in like mannner, but to illustrate still further the importance of a proper system of cleansing casks before any purifying process is applied.

It may seem at first sight but an indifferent matter to bring before an important Association like the present; but when it is considered that there are no fewer than 2,400 public breweries in the United Kingdom, who brew something like 20,000,000 barrels of beer annually, and assuming that at least an equal number of casks require to be cleansed, it becomes a matter of considerable importance how, and at what cost, this enormous amount of work is accomplished.

As regards the cleansing process, it is worthy of note that the first successful introduction of machinery for this purpose was in the year 1843, when the author, in concert with Mr. W. Lymington, produced the machine already referred to, as well as the improved mode of purifying.

Previous to this period, the only known method of cleansing was by the introduction of steam or hot water, or both, assisted by a chain placed inside, and a rolling motion given to the cask by hand. By such means it will not be difficult to see how uncertain would be the internal state of the cask.

The machine invented in 1843 consisted of a double frame, suited to the form and size of each cask, the frames revolving one within the other and at right angles to each other in such a manner as to cause a chain of peculiar construction, assisted by hot water, to traverse completely over every portion of the cask, and so effectually remove all adhering matter. These machines still continue to be held in high repute at many first-rate establishments, and so far as cleansing is concerned, they are nearly, if not quite, equal to anything which has since been attempted in this way. There is, however, one objection to them, namely, they are only calculated to cleanse one cask at a time, which, in such establishments as the two leading Burton houses (whose demand for casks each day amount to thousands), has been a complete bar to their introduction and use. The new machine now placed before the Association not only gets over the difficulty in respect to the number of casks cleansed at one time, but is superior to the old machine in point of speed generally. This machine consists mainly of two circular discs with an upright shaft or spindle in the centre, which has a screw at each end (the threads being cut right and left handed). The two discs have likewise each a corresponding female screw, which, when turned round on the upright spindle (the same being temporarily fixed), it will be easy to see, will cause the discs to advance or recede from each other, according as they are turned to the right or left hand. Such is the mode

* Read at the British Association.

by which the casks are either secured or released from the machine—that is, by turning in one direction, the casks are effectually secured between the two discs; by turning the reverse way, they are released.

Any number of casks which the bottom disc will contain, and even a second tier (if desired) can be fixed and afterwards cleansed at one operation—say two sets of 5 or 10 casks.

A compound motion is given to this machine not dissimilar (so far as the outer action is concerned) to the old machine, but, from the fact of the cask being placed in an upright position in the machine, and likewise surrounding the middle shaft or spindle, the casks themselves, when the machine is set in motion, are twirled about in a manner altogether peculiar and effective.

The best cleansing medium is found to be a small quantity of sharp shingle along with two or three gallons of hot water.

The time occupied in cleansing ordinary dirty casks is about 5 min., and very bad mouldy casks about 12 min. Thus it will be seen, that one of these machines is calculated to cleanse easily 100 ordinary casks, or 60 mouldy ones per hour, at the mere expense of two or three labourers and an insignificant amount of engine power. In large establishments where unheading is still resorted to, the saving to be effected by this new machine must of necessity be great.

With regard to purifying both new and old casks, there can be no doubt that the wisest course for new casks is to divest the wood as much as possible of the coloured juices before it is made up into casks, which is easily done by hot water or steam, and it is afterwards dried by currents of hot air.

Old and tainted casks are found to be cured (within 1 in 200) by partial steaming, and afterwards by exposure to currents of hot air at 450 degs. Fahr.

Experience having sufficiently proved the soundness of this mode of preparing casks for a most important branch of trade, it may seem almost needless to suggest any other method of performing the same work; but the author being the first to discover the importance of applying heated currents to such a purpose, he feels it incumbent on him to state that there is still another element which he is not sure must ere long supersede to a considerable extent the one before referred to. It is that of super-heated steam, the use of which was discovered lately by the author in rather a singular manner—namely, while engaged on some experiments with superheated steam, it occurred to him, seeing that there was an indicated temperature at the time of between 600 and 700 deg. Fahr., that it would be well to try its effect upon a very bad stinking cask, which, being obtained, was subjected to the heat only ten minutes, when it was pronounced perfectly sweet. It is only necessary to add that the same result has attended many repetitions of the system, and although they have not all been attended with the same successful results, the author feels that it has not arisen from any fault in the principle, but from a want of sufficient practical data as to the exact temperature and also the amount of time to which the casks can be safely exposed to this powerful agent.

SOCIETY OF ENGINEERS.

At the last meeting of this society, on Oct. 5, 1863, Mr. William Roberts read a Paper on "Steam Fire Engines, and the late Trials at the Crystal Palace."

In introducing the subject of steam fire engines to the notice of the Society of Engineers, Mr. Roberts said that it was quite unnecessary to enlarge upon the saving that must occur from the use of them as compared with hand-worked or, as they are commonly termed, manual engines. It is sufficient to say, that, from carefully conducted experiments with two engines, having pumps identical in every respect, but one fitted to a manual and the other to a steam engine, he found that from six to seven times as much work is done, with a consumption of 2 cwt. of coal, or say *two shillings and sixpence*, as was done by the manual for *thirty shillings*.

The honour of constructing the first steam fire engine is undoubtedly due to Mr. John Braithwaite, who, in 1829, constructed one that did good service at several large fires in the metropolis, particularly at the Argyle Rooms and Messrs. Barclay, Perkins, and Co's. brewhouse. A full description of this engine will be found in the 12th volume of the Mechanics' Magazine, February 13th, 1830.

In 1832, Mr. Braithwaite constructed another steam fire engine for the King of Prussia; and Mr. Roberts stated that he was informed that it is still at work, although, like the high-mettled racer, it has descended in the social scale, being now used to pump the water from a mine.

Nothing more was done in England for 30 years with regard to steam fire engines; but in the year 1840, the Mechanics' Institute of New York offered a gold medal for the best plan of steam fire engine, and this was obtained by Captain Ericsson, a gentleman who had been for some years with Mr. Braithwaite, and who evidently remembered what he had seen here.

This engine was very similar to Mr. Braithwaite's first engines.

About the same time, a Mr. Paul Hodge constructed a steam fire engine for an association in New York, the principal feature of which was that the steam power was used as an auxiliary to propel the engine.

From this time the steam fire engine made steady progress in America, fire companies were formed, and these being taken under the protection of the State, having certain privileges granted them, became emulous of each other, and anxious to have the best engines that could be got. Some of the most eminent engineers found it worth their while to take the matter in hand, and, as a natural consequence, our cousins across the water had some very good engines whose "puff, puff," could be heard at their fires; whilst we, with our old-fashioned notions, could only hear the "bump, bump," of our hand engines, relieved now and again by the cry of "*beer, oh!*"

Until the year 1852, nothing was done in this country; but in this year the authorities appear to have discovered that working the floats by hand was rather expensive, and one of them was put into the hands of Messrs. Shand and Mason, of the Blackfriars-road, who removed the hand gear and substituted steam power. Steam cylinders were placed over each of the water cylinders, a crank shaft working in slotted cross-heads between them; and all things considered, these engines worked as well as could be expected, except the propelling, which was a miserable failure.

The saving in working this float was, however, so satisfactory, that the authorities decided to have a boat built expressly as a steam fire engine. This was done in 1855, the boat being built by Mare and Co., of Blackwall, and engined by Messrs. Shand and Mason. The steam cylinders, two in number, are 14 in. in diameter by 18 in. stroke, the water cylinders being 10 in. in diameter, also 18 in. stroke. The engines are horizontal—one on each side the boat, and a large Appold pump is placed in midships to propel the boat upon the reaction principle. This engine is about 80-horse power nominal, but is frequently worked to nearly double. It is capable of throwing four 1½ in. jets at the same time; and at the great fire in Tooley-street it worked nearly 400 hours. This engine has lately been altered. The propelling jets are brought above the water upon Ruthven's principle, and although a decided improvement, the float is still very slow for the power applied.

About this time the East and West India Dock Company had a large Downton pump fitted on board their tug-boat "Dragon," to be worked by the boat's engines. This is a very good fire engine, throwing a 1½ in. jet from 180 ft. to 200 ft.

In May, 1856, in a discussion that took place at the Society of Arts, upon a Paper read by the late Superintendent of the London Fire Brigade, Mr. Braithwaite roundly charged the insurance companies with not being anxious to get fires extinguished; and the answer given by Mr. Braidwood went far, in Mr. Roberts' opinion, to explain how it was that steam fire engines had made so little progress in the country. Mr. Braidwood said—"He could also state that the subject of steam fire engines had been seriously considered; but if the fire offices were disposed to incur the cost which six or eight of these engines would involve, there was not at the present time an adequate supply of water from the mains to work any number of them at a fire; there was scarcely a sufficient supply for ten or twelve of the ordinary engines now in use. Therefore, steam fire engines—admitting their great efficiency—were out of the question, until a larger supply of water could be obtained. If he might compare small matters with great, he would liken the steam engines to a battering train—most efficient when well placed and served, but slow of movement and requiring large supplies. The common fire engine, well constructed and not too heavy, might be likened to field artillery, which from its power, but especially from the rapidity of its movements, was invaluable, to carry out the simile. Hand-pumps might be supposed to take the place of musketry, which might be used when and where it was desired—from a hand-basin if necessary. With regard to the supply of water, his impression was, that when they had an adequate supply for steam fire engines, a higher pressure would be given, so that they could work from the mains without requiring the steam fire engine."

Mr. Braidwood lived long enough to see his mistake, and to pen the following in his last report:—"That at large fires beyond the reach of the steam floating engines, the land steam fire engine had been of great service; it is not only the large quantity it throws, but the great height to which it is thrown that makes it so valuable; at the same time, it can be worked as gently as a common (ordinary) engine."

In 1860 Messrs. Shand and Mason constructed an engine (the one just referred to). This worked for something under twelve months; its last appearance being, I believe, at Tooley-street. Its fate was pretty nearly predicted at one of the meetings of the society of Foremen Engineers by Mr. Stabler, reported in the Mechanics' Magazine, March 1, 1861.

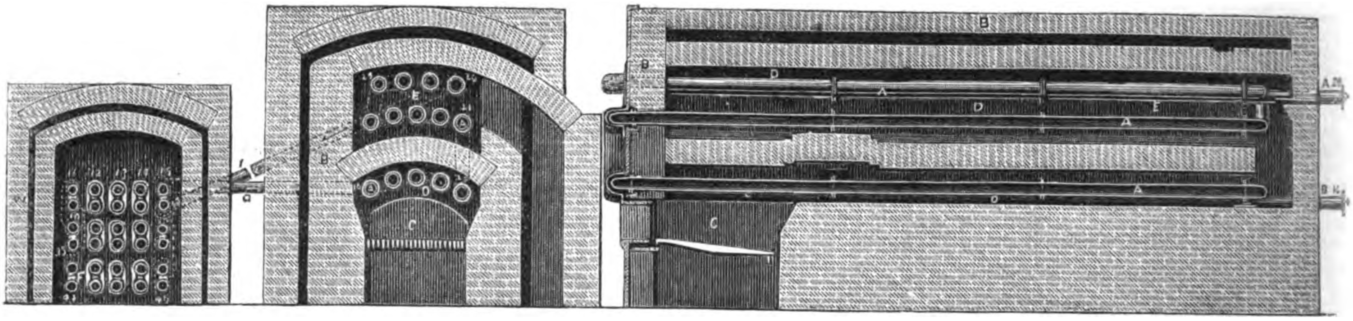
(To be continued in our next.)

A NOVEL APPLICATION OF WATER POWER.

Just forty years since, M. Fourneyron commenced a series of experiments in water power, which resulted in his invention of the turbine or horizontal water-wheel. Since that period considerable improvements have been made in the turbine by different persons, the chief and most useful having been effected by Mr. Schiele, of Manchester, whose ingenious applications of mechanical curves seem to have been fully adapted by him for the production of this form of motive power. One form of his arrangement for supplying power we have recently seen (working the bellows of a powerful organ) at the residence of a citizen of Manchester, where the impression was given that, if all the results achieved by Mr. Schiele be equally successful, a new feature will be rapidly developed in applying water power, especially in cases where a small amount of power may be required at irregular periods; as in the case of working the bellows of organs, driving small lathes, fans for ventilation, printing and other presses, sewing machines, washing machines, &c. In the house referred to, a water-wheel, 4 ft. in diameter, consuming 15 gallons of high-pressure water per minute, formerly employed to work the bellows of an organ in the drawing-room over the cellar wherein the water power was produced, has been replaced by a turbine only 1¼ in. in diameter, with a 3-in. case 1¼ in. wide, supplied by a ⅜-in. pipe, and consuming less than a gallon of water per minute. An ingenious and yet very simple economical regulator, invented by Mr. Eccleston, organ builder, of this city, works in connection with the apparatus just mentioned, by means of which the organist may easily supply his instrument with the required wind by simply turning a handle near the organ. By availing themselves of the ample supply of high-pressure water secured to the city by our Corporation, all persons using machines requiring a small amount of power appear now to have supplied to them by this invention the means of working their machines with no trouble and at a trifling cost; while at the same time this kind of turbine appears to be equally well adapted for turning large mills and works, even when they require several hundreds of horses' power. Orders are now being executed by Messrs. Schiele and Co. for the construction of 50 small turbines, to be used as direct-action fans (the turbine and fan being on one spindle) for the production of the new gas obtained from petroleum. Several powerful turbines will shortly be at work in this locality, when our readers will be able to see and judge for themselves of the extraordinary yet simple effect of this new water engine, which seems to be equally suited for the requirements of the sewing machine in a lady's boudoir, the washing machine and mangle in the laundry, or the hydraulic press and hoist in our huge warehouses. In fact, wherever our Corporation waterworks will enable persons to turn a water tap, and thus to supply at a moment's notice the power required, these machines will be available; while all the risk from fire and the cost and trouble of steam boilers and engines will be avoided.—*Manchester Guardian.*

CLARK'S APPARATUS FOR SEPARATING VEGETABLE FIBRES.

Fig. 1. Fig. 2.



CLARK'S IMPROVEMENTS IN SEPARATING VEGETABLE FIBRES.

This invention, patented by William Clark, engineer, Chancery-lane, relates to the separation of the fibres of vegetable substances and the extraction of their gummy and colouring matters, by subjecting them to the action of water brought to a temperature at which it boils under a pressure greater than that of the atmosphere, either with or without the use of alkalies, or of rubbing, grinding, or beating devices as an aid to maceration. In such method of separation, as heretofore practised the boiler or macerating apparatus has been charged while at a temperature below 212 deg. Fahrenheit, and after closing it the charge has been heated to a temperature of from 300 deg. to 350 deg. Fahrenheit, at which it has been kept for a sufficient time to effect complete maceration, and then the apparatus has been completely discharged and recharged for a new operation. The process conducted in this way involves the loss of all the time occupied in discharging and recharging and in heating up again from below 212 deg. Fahrenheit to the much higher temperature required, and the waste of all the heat contained in the matter at the time of its discharge, which takes place at the high temperature above mentioned.

The object of this invention is to obviate this loss of time and waste of heat, and consists in effecting the macerating process without interruption by supplying and discharging the material and the water necessary to effect maceration in a continuous manner by means of a forced circulation through the boiler or macerating apparatus effected by a pump or other equivalent forcing apparatus.

It also consists in saving the heat of the discharging pulp or macerated material by retaining it under pressure after it has left the boiler or macerating apparatus, and passing the incoming fibrous material and water in a contrary direction to the discharge through a suitable system of pipes or passages properly arranged in contact with or in relation to the discharge pipes or passages.

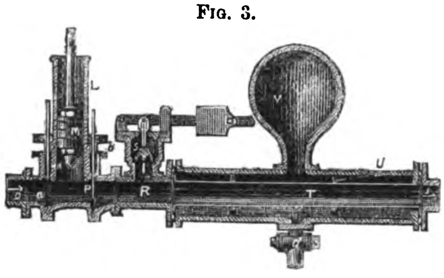
It also consists in forcing the fibrous material through a mill or other grinding, rubbing, or beating apparatus employed in connection with the boiler as an aid to maceration by the combined or simultaneous action of the pump or forcing apparatus by which the forced circulation through the boiler is produced, and of the pressure due to the heat of the steam or water in the boiler.

It also consists in the construction of the forcing pump by which the forced circulation through the boiler or macerating apparatus is produced with sharp-edged valves so applied and operated as to cut any straw or other material which may be left in the valve passages when the valves close, and thus ensure the perfect closing of the valves and prevent leakage.

It further consists in the employment for the purpose of transferring the heat from the discharging pulp or macerated material to the incoming material and water of double or twin pipes, or, in other words, pipes containing two passages through which the macerated material and the incoming material and water can flow side by side in opposite directions.

In the accompanying drawing of an apparatus which illustrates the several features of this invention, fig. 1 is a transverse vertical section; fig. 2 is a longitudinal vertical section of the boiler in the plane indicated by the line y, y, in fig. 1; fig. 3 is a central vertical section of the

Fig. 3.



forcing pump and its appendages for feeding and producing a continuous circulation through the macerating apparatus. Similar letters and numbers of reference indicate corresponding parts in the several figures. The boiler represented is composed of a train of pipes A, A, A, arranged in three tiers, one above another, in a suitable furnace B, B, the lower tier being arranged partly over the fire-place C and partly in a flue D running directly back from the fire-place, and the two upper tiers being arranged within a return flue E above, and the connections between the said pipes are such that there may be a circulation through the whole series—first, through one after another of the lower tier; next, through one after another of the second tier; and finally, through one after another of the highest tier. The first pipe of the lower tier is connected by a pipe G with one end of the train of twin or double pipes F, F, in which the incoming fibrous material and water are heated by the outgoing pulp or macerated material before entering the boiler; and the last pipe of the highest tier, which is the one at the extreme right of the tier, is connected with the mill, by which the fibrous substances after having been boiled for a sufficient length of time are ground, and from which they pass through a pipe to the same end of the train of twin pipes F, F, with which the pipe G is connected, but G connects with the upper and I with the lower compartment of the pipe F, which forms this end of the train. The other end of the train of twin or double pipes F, F, has connected with it the feed pipe J, and the discharge pipe K, the feed pipe being connected with the upper and the discharge pipe with the lower compartment of the pipe F, which forms that end of the train. The train of pipes F, F, is enclosed within a casing W of brickwork or other non-conducting material to prevent loss of heat by radiation. The construction of these pipes is shown in fig. 1, where it may be seen that each has two compartments or passages. The two compartments have no communication at all with each other; but the several lower compartments or passages are connected throughout the whole train, and so are the upper compartments or passages, the upper ones being for the passage of the incoming fibrous substances and water, and the lower ones for discharging the pulp. L, fig. 3, is the barrel of the force-pump for feeding the straw or other fibrous material and the necessary quantity of water for producing its circulation through the trains of pipes F, F, and A, A; M is the piston of the said pump; N and P are the induction an deduction valves, made of steel plate, fitted to slide in suitable guides against steel-faced seats, and having their lower edges bevelled to sharp edges to enable them to cut with a shear-like action against the lower edges of the openings in the valve seats, and thus sever any pieces of straw or other fibrous material that may be in their way as they move downward to close. The valves pass through suitable stuffing boxes, and are connected with eccentrics or other suitable devices which derive motion from the steam engine or other motor by which the piston of the pump is worked. The induction pipe Q of the pump is connected with a mixing chest in which the straw or other fibrous material, cut into pieces of about one or two inches in length is mixed as thoroughly as possible with water by means of suitable agitators. The eduction pipe R has applied to it a safety valve S to prevent any injurious strain in case of any part of the apparatus becoming choked or clogged, and beyond this safety valve it is connected with one end of a pipe T, which is either composed of several thicknesses of wire gauze or finely and closely perforated all over, the said pipe being encased with a strong cylinder U, on the top of which there is an air-vessel V, and at the bottom of which there is an escape cock d; the other end of the pipe T is connected with the feed pipe J. The pipe T serves as a strainer to permit the escape of any excess of water that may pass through the pump beyond what is necessary to carry the fibrous material through the macerating apparatus and effect its maceration; and this excess of water passing into the cylinder U is allowed to run off through the cock d, which is opened whenever it is found by the state of the pulp that an unnecessary quantity of water is passing through the macerating apparatus. The air-vessel V operates in the same manner as the air-vessel of an ordinary force-pump. The mill to which the fibrous material is delivered from the boiler may be of any kind that may be found suitable for reducing the material to a pulpy state without destroying its fibres, and therefore needs no particular description.

LARGE LOCOMOTIVES.

We see it stated that the Philadelphia and Reading Railway has lately built a locomotive engine weighing 56 tons. Of its cylinder dimensions, heating surface, size of wheels, and arrangements, we have no account. We understand that it is designed to be used as a "pusher" for the heavy coal trains up a heavy grade. There are a great many of these monster lomotives scattered around the world. The heavy passenger engines of the Great Western (England) line were for a long time the most colossal in the world. The narrow gauge Crampton engine, "Liverpool," built by Messrs. Bury, Curtis, and Kennedy, for the London and North-Western line, was, in some respects, however, larger. With 18 in. cylinders, 20 in. stroke, and 8ft. driving wheels, it had 2,100 square feet of heating

surface, the boiler being oval in section and containing 300 tubes, 2 3-16ths in. in diameter, and 12 ft. 3 in. long. The weight was 40 tons. The engines originally constructed at Munich to work the Soemmering incline, were of great size, their cylinders being 20 in. diameter, stroke 30 in., whilst the eight coupled wheels of the engine, and the six wheels of the tender, which were also connected by endless chains to the driving wheels, were 3 ft. 6 in. in diameter. The whole weight thus secured for adhesion was about 55 tons. The boiler was 4 ft. 6in in diameter, the tubes were 14 ft. long, and the grate was 5 ft. long, and 4 ft. 8 in. wide. The Engerth engines, of which a large number are employed on the Northern and Eastern Railway of France, have 19½ in. cylinders, 25 in. stroke, and eight coupled wheels 4 ft. 2 in diameter. The boilers are 5 ft. in diameter, and contain 235 tubes, 2 ft. 2 in. in diameter and 16 ft. 5¼ in. long. These engines weigh about 42 tons each. Borsig's tank engines, on the Scarbruck and Manheim line, weigh 44 tons, and have 18 in. cylinders, 27 in. stroke, and six 4 ft. driving wheels. Mr. Brunel's great tank engines, on the Vale of Neath Railway, weigh 47 tons, and have 18 in. cylinders, 24 in. stroke, and six coupled wheels 4ft. 9 in. in diameter. The boilers are 5 ft. 2 in. in diameter, the tubes being 10 ft. 9 in. long. The grates are 4 ft. 10¼ in. long, and 5 ft. 8 in. wide. Some of the engines employed upon the Delaware, Lackawanna and Western Railway have 18 in. cylinders, 24 in. stroke, six coupled 4 ft. wheels, and have 51 in. boilers, containing 91 tubes 3 in. in diameter and 15 ft. 6 in. long. The grates are of the enormous size of 45 square feet, viz., 6 ft. long and 7½ ft. wide across the fire-box. Weight, 35 tons. An engine constructed by Ross Winans, has 22 in. cylinders, 22 in. stroke, eight coupled wheels 3 ft. 7 in. diameter, besides a truck, making 12 wheels in all. The Engine "L'Aigle," constructed by E. Gouin and Co., of Paris, in 1854, for the Western Railway of France, has 16¼ in. cylinders, 31¼ in. stroke, and four coupled driving wheels 9 ft. 4 ft. in. in diameter.

Exceptional cases may demand these monster engines, but the ambition to build them we believe to be far in advance of the real want. Such immense weights driven over our roads tax with great severity every portion of the superstructure, and use up with greater rapidity the common sized rails which have neither the vertical nor the lateral stiffness to resist the disarranging forces residing in these gigantic experiments. Our European neighbours have indulged in these expensive and destructive steam monsters far more liberally than we in the United States, especially in passenger Express engines. The comparatively slow speed of our heavier freight engines, prevents much of the evil to superstructure which must follow the use of heavy passenger engines.—*American Railway Review.*

POSTAL AND TELEGRAPHIC COMMUNICATION IN FRANCE.

THE *Annales Télégraphiques* states that the number of letters passing through the French Post-office, in 1862 was 300,000,000, of which 1,820,000 were registered, and 976,047 were letters containing property of a declared value of 600,000,000 francs. The number of newspapers, pamphlets, patterns, and small parcels, &c., was 190,000,000.

The gross receipts of the Post-office authorities were, in 1861, 66,781,363 francs; expenses, 42,748,373 francs, leaving a balance of 24,032,990 francs.

The accounts for 1862 are not completed, but the receipts amount to 69,906,000 francs.

The number of private telegraphic messages transmitted in 1862, by the telegraphs under Government management, was 1,521,000; the receipts were 5,315,000 francs.

To these must be added the private messages transmitted by railway companies, which amounted in the year to 80,000, producing a sum of 135,000 francs, so that the total number of private messages transmitted reaches 1,601,000, producing no less than 5,451,000 francs. The number of Government messages exceeded 500,000, representing an amount of more than 2,000,000 francs.

It appears, then, that the more the tariff of postal and telegraphic communications has been lowered, the larger has been the total sum realized. The telegraph, so far from diminishing the number of letters, seems to have tended to increase it. The hours when the telegraph is principally in operation are from twelve to three, while the exchange is open, and when business is at its height.

IRON WALLS AND THEIR ARMAMENT.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In dealing with the question of Naval Guns, it is not without design I retain the title of "Iron Walls and their Armament," under which I some time since drew public attention to the vast importance of the subject.

Armour-plate defences to ships and batteries have created a revolution in naval and siege artillery. Guns of small calibre, cast-iron shot and shell, and moderate charges were more than a match for wood and masonry. Those means of attack are futile against iron plates. The whole philosophy of the question lies in the change of the material of the defensive structures—in the resistance of iron compared to timber and bricks or stone. The erection of iron-cased land batteries at the entrances of rivers and harbours is only a question of time. The effect of the Federal fire on Fort Sumter is no more to be taken as a criterion of the value of the American guns, than the destruction of the Turkish fleet at Sinope with Paixhan shells is to be regarded as evidence of the power of modern artillery. The long range at which the Charleston forts have been shelled is simply ascribable to the application of the rifle principle, and by no means to any peculiarity of construction of the guns.

Some public writers, including those who do the war articles in the *Times*, seem to be bewildered by bombardments from distances of four or five miles, apparently unmindful of the fact that those effects are the result of rifling and high elevation combined. The extraordinary increase of range obtained with rifled guns with increase of elevation, is shown in the table of experiments with Armstrong's and Whitworth's 12-pounders, printed in my last letter. With the same charge, 1½ lb. of powder to a 12 lb. shot, or ⅛ the weight of the projectile, the latter gun, at 2 deg., gave a range of 1,198 yds.; at 5 deg., 2,867 yds.; and at 10 deg., 4,226 yds.; thus varying from about ¾ of a mile to 1½ and nearly 2½ miles. By still greater elevation the range might be extended to 4 or 5 miles; but these long ranges result in vertical fire.

In referring to the destructive effects of the Parrot and Dahlgren guns, vertical and horizontal fire are confounded. The real test of the power of a gun is horizontal fire, at point blank, with a heavy charge, a low elevation, and a flat trajectory. Bombardment at long range is a special branch of artillery practice. With the use of rifling it has attained new importance, being effective from distances which were never dreamt of with mortars and smooth-bore guns. But bombardment is rather a means of annoying an enemy and destroying his magazines, or dismounting and disabling his guns, than a direct attack on his defences. The *feu d'enfer* did not determine the fall of Sebastopol. The storm of Dahlgrens and Parrots did not advance the capture of Vicksburg, the surrender of Sumter, or the evacuation of Wagner. The sap, the mine, the breeching battery at short range preparatory to the assault, do the decisive work.

The most erroneous notions prevail with reference to American siege and naval guns. The 11, 13, and 15-in. guns, 200 and 300-pounder shot, are glibly spoken of, as if calibre and weight were the prime conditions for destructive effect; but that idea is a mistake. These large guns are fired with low charges, and give low velocities. Now every practical artillerist and trained gunner knows that, for smashing and penetrative effect, you must have heavy charges producing high velocities. The weight of 200 and 300-pounder projectiles sounds big. The *Times* was fond of imposing on the imagination of its readers by calling the 100 and 150-pounder Armstrong guns 200 and 300-pounders, simply because elongated bolts of the last-named weights were fired from the guns. As well might a double-shotted 68-pounder be called a 136-pounder.

The fact is, if the weight of the shot is increased, that of the charge must be reduced, and by that process propelling force is not gained. The momentum of a projectile, which is the measure of its propelling force, is in the ratio of the square of the velocity multiplied by the weight. That is the law in theory, according to which the products of calculations giving equal quantities, ought to indicate equal effects, but in practice that is not the case; it is found that, for destructive effect, velocity, the "vis viva," is a more important element than weight, the "vis inertiæ." This has been again and again demonstrated in firing at armour-plated targets at Shoeburyness. By the results thus obtained, the theory that penetrating and smashing effects are obtained in a superior degree with heavy projectiles and low charges, is demolished; and this theory, being the basis of the Armstrong system of gunnery, the system itself falls to the ground. The 68, 110, and 200-pounder projectiles, fired with charges of 16, 14, and 10lbs. of powder, give velocities, of which the products of the squares multiplied by the weights respectively are nearly equal quantities; but the effects on the targets do not support the calculations. On the contrary, the reports of the Iron Plate Committee prove, what is well known to every one who has witnessed the experiments referred to, that the indentations on the plates, which are the measure of the force of impact, are—for the 68-pounder, 2¼ to 2½ in.; for the 110-pounder, 1½ to 1¾ in., and for the 200-pounder a slight mark ¼ to ½ in. in depth. The illusion of the tremendous force of the 200-pounder shot was, after a few experiments, dissipated. The heavy masses of iron were found at the foot of the target innocuous, except to break off their own conical heads. There was no resisting this evidence; the great Elswick artillerist himself was convinced of the fallacy of his theory. Since that time, he has been content to have his 100-pounder called a 100-pounder, and nothing more.

So it is with the American great guns. They are vaunted far beyond their merit. They are not, and cannot with safety be, fired with charges exceeding one-tenth the weight of the projectile. Hence the velocities are low, and the smashing and penetrating effects with horizontal fire comparatively ineffective.

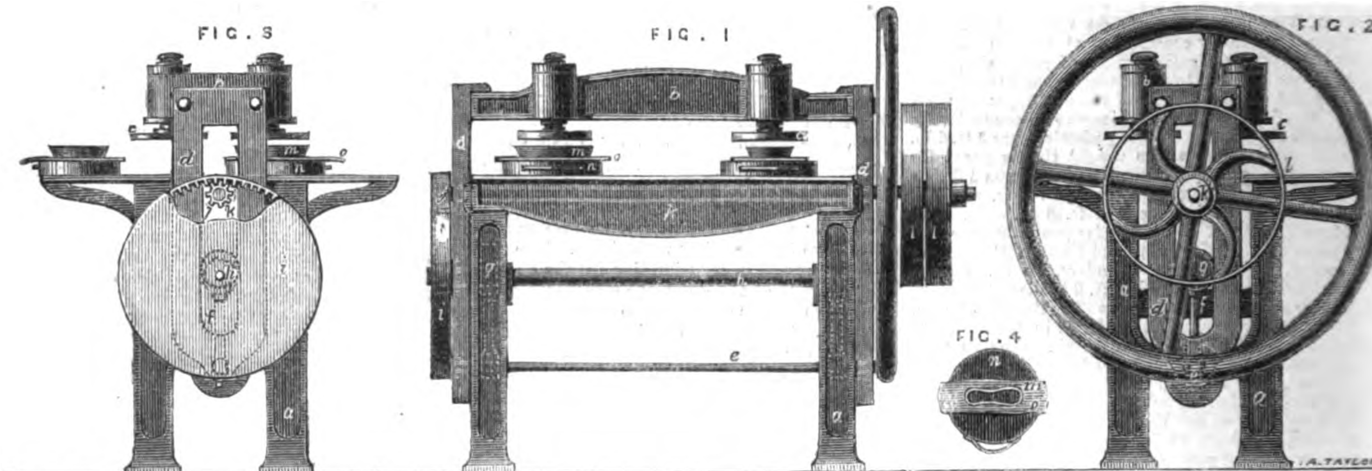
The inherent defect of rifled guns of every service, in this or foreign countries, is the *forcing* principle, by which rotary motion is imparted to the projectile. The compression or expansion of soft metal on the shot into grooves and ribs in the gun, the friction of the iron surfaces of the shot in grinding its way through the twist of the bore, whether on the hexagonal, oval, or ribbed plan, are all more or less forcing systems. The proof that they are so, is the immense loss of propelling force resulting from them, and the necessity of lubrication to protect the gun from bursting by excessive tension. This point is set at rest by comparing the velocities of shot from smooth-bore and rifled guns. Whilst the 68-pounder round shot, with a windage area of 5 per cent., has a velocity of 1,580 ft. in a second, the Armstrong, Whitworth, and other English rifled guns give little more than 1,200 ft., and the American heavy ordnance probably not more than 900 ft. to 1,000 ft.

The gun wanted for the Navy, and for coast or siege batteries, is one which shall be rifled on a plan which is not a forcing system; which shall impart rotary motion to the shot with no more strain on the gun than that resulting from the weight of the projectile; a gun which, under those conditions, may be fired with heavy charges without bursting, producing high velocities and smashing effect at long ranges. No such gun exists at present; it can only be produced by abandoning the vicious principle of obtaining rotation by forcing the shot to mould itself into or to grind its way through the rifling. The *morgue* at Woolwich of suicidal rifled guns furnishes ample evidence of the cause of self-destruction. They invariably burst at the part of the chase where the shot, suddenly put in motion by the explosion, has to force its entrance into the grooves or ribs which constitute the rifling.

I may be thought presumptuous in advancing these opinions. My object, as it was in the armour-plate question, is to promote discussion and elicit truth.

CIVILIAN.

GIMSON'S PRESSES FOR PUNCHING OR CUTTING LEATHER.



GIMSON'S PRESSES FOR PUNCHING OR CUTTING LEATHER.

This invention, patented by Mr. J. Gimson, of Leicester, M.E., relates to that description of presses in which knives or cutting tools with sharp edges bent in any desired form are used to cut out pieces of particular shapes. These cutting tools are usually made about two inches deep, and two, three, four, or more tools are frequently adapted to the same press simultaneously, in order to economize time and labour; but as the knives or cutting instruments and also the under blocks do not always wear away equally, considerable difficulty is experienced in using in the press at the same time several knives and blocks of different depths or thickness.

The object of this invention is to obviate the inconvenience arising from using knives and under blocks of different depth or thickness; and to this end the patentee employs, in combination with the moveable part of the press, as many adjustable pressing surfaces as there are knives or cutting instruments, so that each pressing surface may be adjusted separately to suit the knife with which it is intended to be employed. It is preferred that this adjustment should be made by means of adjusting or set screws, so that the pressing surfaces may be screwed up or down according to circumstances. It will be evident that, as a modification, the under block on which the substance to be cut is placed may be made adjustable vertically instead of adjusting the moveable upper plate or pressing surface.

In the accompanying drawing is shown a machine or press for cutting or punching out soles constructed according to this patent. Fig. 1 is a front elevation of the press, showing two cutting knives and blocks; fig. 2 is an elevation of one end of the machine; fig. 3 is a similar view of the opposite end of the machine; and fig. 4 is a plan view of the wooden under block, knife, and piece of leather to be operated upon.

a, a, is the main framing of the machine; *b, b*, is a moveable cross-head provided with adjustable pressing surfaces or plates *c, c*, which are moveable vertically by means of their respective screws, as shown in the drawing. The cross-head is supported by the side arms *d, d*, which are connected together at their lower ends by the cross-shaft or rod *e*. Links *f, f*, shown by dots in figs. 1 and 3, connect the shaft or rod *e* with the eccentrics *g, g*, on another cross-shaft *h*, on one end of which is keyed a box wheel *i* provided with internal teeth, into which gears a pinion *j* on one end of the driving shaft *k*, which may be driven either by hand labour or by means of a band passed round the pulleys *l, l*. The knives or cutting instruments are shown at *m, m*, and the under blocks at *n, n*, the strips of leather *o, o*, being between the knives and the blocks. Upon motion being communicated to the driving shaft *k*, the eccentrics *g, g*, will draw down the cross-head and adjustable pressing surfaces *c, c*, and by causing them to press on the top of the knives, the latter will cut through the leather on the block *n*. It will be evident that as the pressing surfaces *c, c*, are adjustable vertically by means of their respective screws, their position may be regulated and adjusted with great nicety to suit the varying thicknesses of under blocks and the depth of the knives or cutting instruments. It will be evident, as a modification of the above, that the cross-head *b* may remain stationary and the under blocks be made to rise and carry up the knives and under blocks to and against the pressing surfaces, or the under blocks *n, n*, may be made adjustable vertically instead of the pressing surfaces *c, c*.

CLEANING SHIPS' BOTTOMS.

An improved apparatus for effecting this purpose, depending on the following principles, has been recently granted protection. It is the invention of Mr. M. Hutchinson, of Devonport.

As the weight of a cubic foot of sea water is more than 64 lbs., and that of a cubic foot of cork about 15 lbs., the difference between the two—viz., 49 lbs., must represent the buoyancy, in other words, the upward pressure, of a cubic foot of cork when immersed in the sea. Mr. Hutchinson proposes that two flexible, we may call them, "mattresses," about 10 ft. long, 5 ft. wide, and 1 ft. deep, made of canvas (rendered waterproof probably by having been steeped in a preparation principally composed of linseed oil), be lightly stuffed with cork parings, or cotton, or other light suitable substance. Were it preserved air-tight, no stuffing would be necessary. It might be blown out when required for use, like an air-cushion, until sufficient air was pumped in to resist the pressure of the sea. A slight netting, or many loops, must be attached to the upper surface of the mattress.

This surface being an area of 50 square feet (representing a pressure, when immersed in water, of upwards of 2,450 lbs.), that 50 brushes (each 1 ft. in area, hexagonally shaped), with backs of light wood, or a fabric of gutta percha, be fastened to the net, or loops, by light waterproof lashings. Thus, the whole mattress will form one large buoyant flexible brush, or scrubber, in which each separate brush will receive its own distinct pressure, and thus all parts of the ship's bottom will be felt and acted on, however undulating may be the surface.

That a frame of pine wood (two sides and a bottom), strengthened at the line of junction by metal, but not so heavily as to destroy buoyancy, be made to embrace the keel, and travel along the bottom of the ship.

That this traveller, with the scrubbers attached to it (one for each side), be lowered from the bow of the vessel, and with removeable weights be sunk into position.

That by buoyant Manilla ropes running from the scrubber and traveller, through pulleys fixed at the bowsprit and spanker-boom, the scrubber and traveller be simultaneously drawn fore and aft until the part of the bottom rubbed by the scrubber (a strip 5 ft. wide) be sufficiently cleaned. That as soon as one length of 5 ft. width is cleaned, the traveller and scrubbers be hoisted up, and the scrubbers, when freed from weeds, be removed 5 ft. further from the traveller.

As the scrubbers are further and further removed from the traveller, the sides of the ship in contact with the scrubber become more and more vertical, and in the same ratio the pressure from buoyancy decreases; but, on the other hand, the useful strain upon the ropes from the traveller becomes greater, and it will be only necessary to give a stronger pull on the tackling fixed to the upper edge of the scrubber, and passed over the side of the vessel—or, more probably (to allow some play), throw over a rope extended from the rigging of one mast to the rigging of the next. The ship would have a "list" to the side that is being cleaned.

The keel would be cleaned by brushes fixed inside the traveller.

When the bottom is much fouled, it may be necessary to use brushes made with fine copper wire in lieu of whalebone; and in extreme cases metal scrapers, somewhat in the form of the letter T, would be substituted for wire on the brushes.

Scrubbers only 10 ft. by 5 ft. by 1 ft. have been spoken of; but for large ships it is presumed they might be of much greater dimensions, and be 2 ft. thick instead of 1 ft. This would more than double their buoyancy, for the additional foot would add a mere trifle to the weight. If merely filled with air they could, when emptied, be stowed away so easily, that their bulk would not be objectionable; and the traveller would occupy but little space, for its sides are supposed to be made removeable from its bottom.

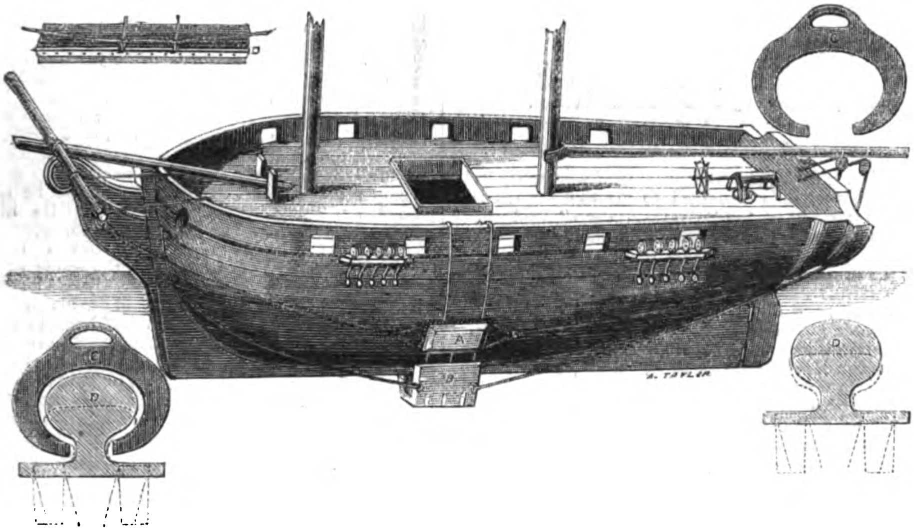
The scrubbers are kept extended by the four edges of their upper surface having a pine rod passed through one continued loop. That the scrubbers may lose none of their flexibility, the rods are divided into parts by over-lapping joints. To preserve its shape, the scrubber would be quilted in several parts like a mackintosh cushion.

The traveller can be used to clean the rudder, but it would be worked on the opposite principle to buoyancy. With brushes fixed inside it, it might be lowered over the stern and made to embrace the rudder, and sink by weights attached to it.—It would be raised, again to sink, and so on; which continued action would soon scrub off the weeds. The stern-way given to the ship would prevent the traveller's flying off.

It is obvious that the more the helm is ported the greater would be the pressure of the brushes against the port side of the rudder, and *vice versa*.

To ships the form of whose run and shallow keel prevent the easy adjustment of the traveller, and to many steamers, a guiding bar (about 1½ in. in diameter, with a flange) might be fixed along the bottom and bow close to the keel, and up the

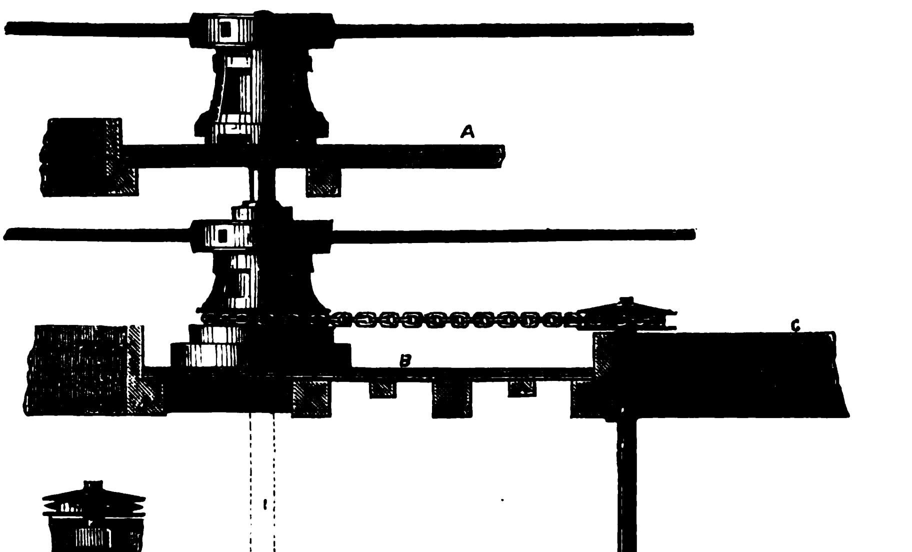
HUTCHINSON'S APPARATUS FOR CLEANING SHIPS' BOTTOMS.



run. On this bar, three or four shackle cringle rings could be made to travel, which rings would virtually become the traveller, and cords would run from them to the scrubber. The keel could be cleaned by one of the scrubbers being passed under it. The scrubber would be retained in position by the rings being hooked to both of its sides. This bar would be kept free from weeds by a close-fitting sharp-edged ring being occasionally run along it. Copper-bottomed vessels would probably have a bar of Muntz's metal.

The accompanying drawings require little explanation. A is the mattress or scrubber, B is the traveller, D ropes and tackle, C cringle ring.

APPARATUS FOR MOVING SCREW STEAMERS IN A CALM.



MOVING SCREW STEAMERS IN A CALM.

Captain M. Conolly, R.N., has suggested certain arrangements for rendering manual power applied to the shafts of screw steamers available for moving them through short distances in calms, &c., when the steam is not up. The plan is a very simple one, and will be easily understood from the accompanying drawing—merely a spindle I down the nearest hatchway to the capstan on the main deck B, connected to the screw shaft by bevel wheels E, and to the capstan by a small length of chain messenger. Or the spindle of the capstan itself may be elongated and brought at once to the screw shaft; but in this case the multiple power would be greatly reduced, and more expense and inconvenience would be attended in its fitting; whereas the plan illustrated may be fitted to any ship, and it is shipped and unshipped in a very few minutes—certainly as soon as the screw could be lowered. We understand that Captain Conolly has submitted his invention to the Admiralty.

AMERICAN COPPER.

We extract the following article on this subject, from the *Scientific American*. It is certain that at no distant day the supply of copper from American sources will materially influence our own markets, and the question is well worthy of attention :—

There was a period in the history of the world when iron was unknown in the arts. The utensils and armour of the most civilized nations in those days were made of bronze—an alloy, composed of copper and tin. After the discovery and application of iron and steel, the use of copper and bronze declined for many purposes; because steel and iron were stronger, and could be produced at a much less cost. No one can over-estimate the value of the general application of iron in the useful arts. But copper is also a most valuable metal, and for some purposes it has no equal. In the art of electro-metallurgy it occupies the front rank as a conductor, and it still forms the chief material of most alloys. For metallic statuary, and brass in all its various forms, it is the principal metal employed, and the demand for it is on the increase. Iron is so subject to corrosion, especially when exposed to a saline atmosphere, or to the action of salt water, that copper is preferred to it as sheathing for ships and for many other purposes, where durability and not strength is the main object. It is also used exclusively for the great pans in sugar refineries, as also the stills in spirit distilleries; and with the increase of all classes of manufactures and chemical products, an increased supply of copper is also required. The copper regions of the United States are of great extent, and the metal of the Lake Superior mines is the best in the world. The present yield of the mines of this region is about 8,000 tons per annum; this amount being twelve times greater than the yield ten years ago. The total annual copper product of the world is about 70,000 tons, Chili supplying 16,000 tons, and Great Britain 17,000 tons; but in the latter country, about 32,000 tons are smelted annually from native and foreign ores, and 25,000 tons of the metal are exported.

The American copper mines are but in their infancy, and their future prospect is cheering; for the ores are perhaps the richest on the globe. Nowhere have such masses of pure copper been found as in the Lake Superior district. And we learn from the *California Farmer*, of the new mines in Calaveras county, in the district called Copperopolis, that the ores of that region are second to none in richness, while they far surpass those of England. Five mines have been opened, which have been worked by skilled Cornish miners, and many thousand tons of ore have been brought to the surface. The best ores are said to yield about 26 per cent. of copper, and one of the mines now forwards about 15 tons of picked ore daily. If copper could be produced at less cost, far more of it would be used in the arts. Attention should, therefore, be directed to improvements in mining and refining this metal so as to reduce its cost. Were it not for its great price, the bronze made of copper and aluminium would be employed for making parts for marine engines, as a substitute for wrought iron, because it is much stronger than that metal, while it is also proof against corrosion by salt or fresh water. In the Newcastle district, England, sulphuric acid is now manufactured in large quantities from sulphurets of copper, instead of the crude sulphur formerly imported from Sicily. After the sulphur is driven off by the heat, the waste or ash is smelted for its copper, and the operation yields a profit, with ash containing only 2 per cent. of metal. Cheap coal is the prime agent for smelting copper ores economically, and this can be obtained in several sections of our country. So far as we have been able to ascertain, there are six copper-smelting establishments in the United States, namely, at Detroit, Mich.: Cleveland, Ohio; Pittsburgh, Pa.; Baltimore, Md.; Boston, Mass.; and New Haven, Conn. This is a large number, considering the short period since copper became an American product of any consequence; but with our great natural resources of rich ores, our smelting establishments should turn out 16,000 instead of 8,000 tons annually, within five years.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post-office orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

RECEIVED.—G. S., J. R., J. M., D. and W., J. N., Mr. S., W. W., F. J., R. T. S., C. A. B., K. and Co., A. P. and Co., B. J.

T. K. (Whitehaven.)—We are not certain of the exact day; it was early in March.

A WORKMAN (Peterborough).—In calculating the effective weight of your safety-valve, you must include every portion of the balance, which requires to be raised before the steam can escape. In your case, if you hold the balance upside down, by the rod which fastens it to the boiler, the index will show you on the scale of pounds how much you must add for the balance. The effective weight is probably about 138 lbs.

T. H.—Your suggestion is not a bad one, and seems practicable.

A STUDENT (Leeds).—1. The breaking weight of a bar of wrought iron of good quality, 1 in. square and 1 foot long, supported at each end and loaded in the centre, may be taken at 2,290 lbs. 2. Iron should never be loaded to more than one-fifth of the breaking weight with a quiescent load, or with more than one-tenth if liable to jerks. The limit of elasticity to which you refer depends so much on the quality of the iron and the mode in which the strains are applied, that we cannot give you a general answer within reasonable limits which would be superior to those with which you are already familiar. 3. A beam fixed at one end and loaded at the other will only sustain one-fourth of the load which it would endure if supported at both ends. We shall be happy to solve any particular case if you will submit it in a compact form. You should extend your knowledge of the strength of materials by enlarging your reading, and drawing your own deductions when opinions clash.

Correspondence.

BOILER EXPLOSIONS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—The discussion which Mr. Clark has forced upon me is, I fear, directed less to a question of science than to one of good faith and gentlemanly behaviour between ourselves. Within the last month he has for the first time publicly claimed to have given me, in September, 1859, all or nearly all the facts and ideas which I have since advanced in explanation of the violence of boiler explosions. Now I attach but moderate importance to the credit which my reasoning upon this subject may obtain for me; but it is most important for me to escape the discredit which a direct charge of a plagiarism must, if uncontradicted, fix upon me. It is for this reason only, and from no love of controversy, that I distinctly deny Mr. Clark's version of our earlier conversations upon this matter; and I shall endeavour to adduce something like evidence, in a form upon which you, Sir, can decide for or against me. Mr. Clark states that he "started the projectile theory" in a conversation with myself and my friend Mr. Holley, "shortly after" the "Great Eastern" explosion, and that he, Mr. Clark, had first put a "direct question," involving the whole explanation now in dispute, and that neither of us "made any reply." I have referred this statement to Mr. Holley, and the following is his answer, penned without thought of publication, but for which he has since kindly given me full permission.

"3, Pelham-crescent, Hastings, Oct. 1, 1863.

"Dear Colburn,—My recollection of several conversations between us, about the explosion, *before* the meeting in Clark's office, is distinct enough, but what was said I cannot remember. The impression remains distinctly on my mind that you suggested the sudden generation of steam, upon the reduction of pressure by rupture, as the groundwork of the percussive theory of explosions. I also recollect that Clark mentioned the shutting together of the inner wall of the chimney, forming a huge piston, as the cause of the superior upward movement of the explosion. Of course, giving no thought to the speakers, but only to ideas derived on the occasion referred to, I cannot absolutely swear to anything except that my notions on the subject became a consistent theory on the occasion of that conversation in Clark's office. I am certain that Clark did not suggest the theory to me in any private conversation, and I certainly shall not allow the impression to get abroad to that effect.

"Yours truly,
"A. L. HOLLEY."

Mr. Holley had, on the evening of September 10th, 1859, very fully explained to me the construction and working of the "Great Eastern" feed water casing, and, at that time, I presume that none in London, except those who had, with himself, left the ship that day at Portland, could have known the *particulars* of the explosion. My opinion was formed at once, and I expressed it to Mr. Holley. He, listening to me, could not, of course, experience the feeling which a rapid induction and a distinct conclusion of my own left upon my mind, and he naturally, therefore, cannot remember the terms of our conversation quite as distinctly as I do. Now, as to the subsequent conversation in Mr. Clark's office. In my letter to you of the 2nd instant, I did not, as Mr. Clark now assumes, state that this conversation was after September 16th, 1859, but that it was a "few days after" the time, September 10th, when I fully believed Mr. Holley understood and shared my views—a belief which is still nearly justified by his distinct recollection that I, in several conversations *before* our meeting Mr. Clark, "suggested the sudden generation of steam, upon the reduction of pressure by rupture, as the groundwork of the percussive theory of explosions;" although it appears that Mr. Holley's ideas did not acquire the consistency of a complete explanation until after the conversation in Mr. Clark's office, where I stated my veiws at greater length and with many illustrations. This I did because, much to my surprise, as I well recollect, Mr. Clark did not appear to see that which I thought was as clear as noonday. Now, as to the date of this conversation. It could not have been on Sunday, the 11th, and it was not, as Mr. Clark now states, on either Monday or Tuesday, September 12th or 13th. Mr. Clark must well remember that the conversation in question bore very severely upon certain opinions which had been broached in the *Times*, as to the decomposition of steam in the feed water casing, and as to the possibility of an incredible pressure previous to explosion. Mr. Clark, by referring to his file of the *Times*, will find that those opinions appeared on Wednesday, September 14th, and I find by my diary that I did not meet Mr. Clark until Wednesday, and I had then already written so much of my article on the "Great Eastern" disaster as explained the cause of the explosion. This portion of my article, containing the explanation in dispute, was in type when I met Mr. Clark. It was then of the usual length of a "leading article," and I considered it finished. When, however, I saw the *Times* of September 14th, I was strongly tempted to throw aside what was already in type, and to begin at a fresh starting point. I finally, however, decided to extend what I had written, by a criticism of the *Times'* correspondence; and so the article was lengthened to two columns. I distinctly remember this; and the article itself bears almost positive internal evidence of having been written by instalments. I, with Mr. Holley, met Mr. Clark on Wednesday; but no such conversation as he, in his letter to you of the 25th ult., professes to narrate took place. Which of us first commenced to speak I cannot say, nor what "direct questions" were asked; but I entered upon the subject with the feeling of one who has a clearly conceived idea of his own which he is about to impart to another. I was surprised that Mr. Clark did not appear to understand me (nor to understand Mr. Holley either, for he said much in support of my views), and I wondered that Mr. Mr. Clark should speak of a "huge piston," which seemed to be referring the explosion to steadily exerted pressure. I gave my own views at great length, and Mr. Holley did then, at least, fully understand them as a "consistent theory." Not so Mr. Clark. For many weeks afterwards, when I repeatedly went over the same ground with him, he gave no assent to what I said. I was writing all the while upon the subject, and no article of mine, down to November 4, 1859, contained any idea given me by Mr. Clark; nor had he, until then, given me any ideas whatever upon this subject. On the 4th or 5th November, I was in his office again, and he, for the first time, appeared disposed to admit the justness of my explanation. Then it was that he gave me two facts of importance, bearing out my inference that steam acted percussively in a boiler explosion. These facts were the "spring" of the Cornish engine covers, and the jump of the indicator piston above the boiler pressure. I did not know at the time that these very facts had formed the groundwork of a Paper, by Mr. Parkes, on the percussive action of steam, read upwards of 20 years ago before the Institution of Civil Engineers. Both facts were mentioned in the *Engineer* of November 18, 1859, and I gave Mr. Clark credit for both in my tract (p. 44). The evening of November 5, 1859, I spent with Mr. Clark at his lodgings. He then entered fully into my views, and he pointed out why an empty boiler, heated red-hot, could not be exploded by filling it with cold water. So impressed was I with the growing importance of a rational theory of explosions, that I then determined to write a tract upon the whole subject. I had a high respect for Mr. Clark's knowledge of the properties of steam, and for his ability as a writer; and I had the utmost confidence in him as a gentleman. I proposed that he should give me his assistance in preparing the tract—I to write all but the chapter on the "red-hot plate theory"—(not that upon the decomposition of steam). It was important to clear the ground of existing theories, and I felt that Mr. Clark might help me in many ways. He unhesitatingly admitted, as I was quite sure he would, that the percussive theory was mine, and, so far as he and I were concerned, mine only. He as readily assented to having my name over his on the tract, the necessity for which I mentioned to him in order that there might be no misunderstanding. He appeared not only satisfied, but, as I thought, pleased, to share with me whatever credit there might be in the matter. As for myself, it was enough that Mr. Clark was my *friend*. On the 9th November, I again saw him for a few moments; and I said to him that the tract might be larger and costlier than he had counted upon, and that, if he objected to share the expense with me, I would assume the whole myself, of course, without prejudice to our mutual authorship. On the 24th November, 1859, I wrote to Mr. Clark, acknowledging the receipt of a cheque for a sum of money, upon an account between us, and I took occasion to say that I had been too much hurried to begin the tract, but that it should not drop, and I added, in substance, that he had given me nearly all I knew of the action of steam by momentum. Such was the value I placed upon the facts he had given me on the 5th of the same month, for he had contributed absolutely nothing to my many previous articles on explosions in the *Engineer*. Of course, I had no idea that he would afterwards twice print, as he has done in your columns, and without my permission, such an extract from such a note, or I should have been more explicit in my acknowledgment. Time slipped away, and still the tract was not begun. Some time in January, 1860, I observed that Mr. Harman, the then engineer to the Manchester Boiler Association, had adopted my explanation of boiler explosions in his annual report for 1859. Immediately afterwards, I found that Mr. Clark was privately claiming all I had written upon the subject as his own. I at once called upon him, and kindly but earnestly remonstrated with him, and I went over the whole case between us. He heard me out, excused himself from replying, and said we had best discuss the matter in the presence of witnesses. There was nothing, perhaps, objectionable in this, but I own that I did feel hurt that Mr. Clark should propose it. Mr. Holley, the principal "witness," had returned to New York. So I wrote Mr. Clark, appealing to his candour, if I could no longer count upon his friendship. A tedious correspondence was the result, and it ended in his losing his temper, his last letter closing with an oath. In the meantime he wrote the letter which appeared in your columns, February 10th, 1860. He advanced an idea there which had not, I think, up to that time occurred to me, but I cannot even yet quite adopt it, and you, Sir, have already taken exception to it. Such as it was, however, it was Mr. Clark's, and I have always given him full credit for it, transcribing his letter from your columns into my tract. That letter raised no claim to anything in what I had written. In April, 1860, my tract came out, and Mr. Clark was silent. Some months afterwards appeared the 20th volume of the eighth edition of the *Encyclopædia Britannica*. In Mr. Clark's article on the Steam Engine, the percussive theory or "projectile theory" (I think "explanation" a better word) was introduced, and over the initials "D.K.C.," a general credit for materials incorporated in the article was given to the *Engineer* newspaper. In May, 1861, Mr. Clark wrote two letters, which appeared in your columns, in which he insisted that the action of the *water*, as suggested by himself, was "the *only* novel idea in the argument." "The

writer of the articles in the *Engineer*, in 1859," said Mr. Clark "appeared to have had some notion of electrical action in his mind," albeit that Mr. Clark well knew, that of all hypotheses, that of electrical action in boiler explosions found least favour with me. I had repeatedly controverted it, as my writings abundantly show, and in our private conversations Mr. Clark and I had but one opinion upon the matter. In his letters of May, 1861, Mr. Clark ingeniously attempted to show that all which I then claimed and still claim as my own was, not *his*, but Harshman's. This went for nothing with me, for I have by me all, I believe, that Harshman ever wrote upon boiler explosions, and I was perfectly familiar, as early as 1857, with his notions of "polar forces" and "etherial caloric." With this formal ascription to another of all that I have ever claimed in the matter, Mr. Clark rested, until, the other day, finding that the Astronomer Royal had employed the explanation in dispute, he determined boldly to claim the whole for himself. I trust that I have now said enough—I regret that it should have been so much—as to Mr. Clark's share in the origination of the percussive theory of boiler explosions.

I am, Sir,
Your obedient servant,
ZERAH COLBURN.

3, Upper Bedford-place, Russell-square,
Oct. 10, 1863.

P.S.—I send you herewith a volume of the *American Engineer* for 1857, and of which Mr. Holley and myself were the editors and proprietors. You will find in it a number of articles proving how far my mind was prepared to form the present theory of explosions in 1859. I had dwelt strongly upon the distinction between rupture and violent explosions, and also upon the amount of steam which could be disengaged by water previously heated under a pressure greater than that of the atmosphere. Z. C.

Miscellanea.

The Government have seized the two notorious steam-rams which were being built for the slaveholders, and have given the world a guarantee of peace between England and the United States. Why does not the Government go one step further, and seize the builders of the ships, who, in defiance of moral and international law, would, to promote their own interests, endanger the peace between the two great branches of the Anglo-Saxon family?

Since we noticed Hart's metallic fasteners a fortnight since, we have tried them, and found them to be simple, cheap, and useful. Before long we expect to see them as universally used as india-rubber bands. We are not surprised to find that the fasteners are used at all the Government offices, at many of the banks and railway stations, by literary men, architects, lawyers, and others, and that wherever they are used they are highly appreciated.

The number of prize vessels taken into the port of Philadelphia since the beginning of the war is eighty-five. The most valuable, including the cargo, was the steamer "Bermuda," which realized more than half-a-million of dollars. Several of the late prizes, which brought heavy cargoes of cotton, realized large sums.

The Esmeralda *Times*, in speaking of the progress of the work upon the Stanford tunnel, in Aurora, notices the following ingenious expedient for furnishing light for the workmen during the day time:—The tunnel, the most of the day, is worked without using candles. Mr. L. L. Deming, the financial secretary of the company and acting superintendent, has found a more economical light; he uses the sun to work by. The tunnel is so admirably situated, and the cut being so wide, that it enables him, by the use of a mirror, to reflect the full rays of the sun quite into the end where the men are at work, and it is so light that a paper can be read as easily as on the outside. The above tunnel is in about 150 ft., with an open cut at its entrance, quite large in extent and height. Miners in other localities, driving tunnels, will do well to profit by this hint. The light introduced as above, is not only free of cost, but must be infinitely better than that derived from candles.

The Board of Admiralty, with the Controller, and Mr. Reed, Chief Constructor of the Navy, have for some time past had under consideration the necessity of providing a number of efficient gun-vessels to replace the condemned gun-boats at Haslar and other yards, and a design has been agreed upon. The new vessels are to be built of iron and armour plated, and they will be propelled upon the twin-screw principle, which has been proved to be admirably adapted for vessels of this class.

The "Tecumseh," iron-clad monitor battery, was launched from Secor's yard, at Jersey City, on the 12th inst. The vessel is of the new lot of monitors ordered, and has an unusually good model; she is 235 ft. long, 46 ft. beam, 14 ft. deep, and draws 14 ft. of water in fighting trim. She has one turret, and is in other respects similar to all the other ships of her class. Two more batteries are nearly rerdy at this yard.

An American paper says that an engine is now building in New York city for one of the new sloops-of-war. The cylinder is 32 in., and the piston has 8 ft. stroke; it is stated that 100 revolutions per minute are guaranteed; this is equal to a piston speed of 1,600 ft. per minute. When it is considered that 600 ft. is far better than most engines do, it will be seen that quite a novelty is in store for the engineering community. If the time had been stated in seconds instead of minutes, the velocity of the piston would equal that of a Parrot shot.

We hear, says the *Army and Navy Gazette*, that experiments are soon to take place with the Armstrong 600-pounder in firing at a floating target representing a portion of the "Warrior's" side, and that the target built upon Mr. Reed's plan of very thick plates, slight backing, and a two-inch skin, will also, ere long be fired at. We think, therefore, that our naval and military friends interested in these matters should hold themselves in readiness for a run to Shoeburyness in about a fortnight or three weeks from this time.

The *Times* of Monday strongly advocates the introduction of the twin-screw principle into the Navy.

It has become a question of very great importance—"What are we to do to keep our iron ships clean *under water?*" This subject has been well discussed and well tried, but up to the present moment we have nothing *proved* which will keep our iron ships clean for a twelvemonth. Under these circumstances, it becomes absolutely necessary to have the means of cleaning these ships from time to time without the delay and expense of docking, which on some stations abroad is impossible, as dock accommodation does not exist. The result of some experiments tried within the last day or two at Chatham, may lead to the much-desired solution of this difficulty. H.M.S. "Recruit" was, by desire of the Admiralty, partially cleaned whilst at anchor in the Medway, by an apparatus, the invention of Captain H. F. Mackillop, R.N., the principle being simply the application of lime and other substances under water, the action of which whilst slaking is fatal to grass, fish, shell, and all animalculæ. Although we learn that the result has been for the present unsatisfactory, we hope that further improvements may render the process really useful.

Her Majesty's armour-plated screw steam-ram "Valiant," of 34 guns and 800-horse power engines, was launched in a most successful manner on Wednesday afternoon, in the presence of many thousands of spectators, at the Admiralty-yard, Isle of Dogs. The length of the "Valiant" over all is 380 ft.; breadth, extreme, 56 ft. 3 in.; and depth from the spar deck, 39 ft.; burthen, 4,144 tons, builders' measurement. She is a sister ship to the "Hector," which was launched from the Clyde at the close of last year. Within the armour of teak and iron, the "Valiant" is a perfect web of wrought-iron ribs and girders, rendering her, probably, one of the strongest ships afloat. The propelling machinery will consist of a pair of horizontal engines on the double-piston rod principle, manufactured by Messrs. Maudslay and Field. The cylinders are each to be 82 in. diameter, with a stroke of 4 ft. They will both be surrounded with steam jackets, which are supplied with steam direct from the boilers; the ends of the cylinders and the cylinder covers are also to be cast hollow, and supplied with steam in the same manner. The screw propeller is 20 ft. diameter, with two blades, constructed so that the pitch can be varied from 22 ft. 6 in. to 27 ft. 6 in. When working full power the engines are expected to make about 60 revolutions per minute. There will be six boilers, placed three on either side of the vessel, with the stoking-room between them.

Since the commencement of the American war the tin-plate makers of South Wales have gone through a rather severe ordeal, as the United States was one of their principal markets, and in fact the charcoal plate-makers depended almost entirely on that country for their sales. The consequence was that several works were stopped, and many others only partially employed. During the last 12 months, however, there have been indications of returning prosperity, and some of the works that were stopped have again commenced operations, and those that were kept going throughout the depressed times are now more fully employed than before for a long time, and new works are about to be started in different parts of the district. The coke plate from its cheapness and other circumstances has of late commanded a more active demand than the charcoal, and the coke plate works are unusually well employed. The average quotations for I C charcoal are 27s. to 28s. at the works, and I C coke 21s. to 22s.

The Paris correspondent of the BUILDING NEWS, says:—A project is talked of for the formation of a Metropolitan Railway in Paris, similar to that in London. It is to go from the Opera to the Bastille and St. Maudé, and to have stations at the Palais Royal, the central Halles or Markets, and the Hotel de Ville. The line (a single one) from the point of departure will be at the height of a second floor, and by means of aerial bridges traverse the Rues Louis le Grand, d'Antin, Neuve St. Augustin, St. Anne, and Fontaine Molière. From that street to the Rue Richelieu it will make a curve, and be carried to the Palais Royal at the same height. The station at the Palais Royal is to form a gallery parallel with the Galerie d'Orleans. The shops now opening to the garden will form the side. The line is then to pass between the Halle du Blé and the Rue des Deux Ecus to the Halle aux Draps, which is to form the station of the Halles Centrales. The station is to be double. The upper one will be composed of plates receiving each a train, which will be made to descend whilst another train ascends. The trains will thus be instantaneously placed without the necessity of changing places in the subterranean station. The railway is then to continue by a tunnel with two lines by the Rue des Halles, the Rue St. Denis, and the Place du Chatelet. It will emerge under the Quai Lepelletier, and continue on a steep bank. A station will be made under the Pont d'Arcole, opposite the Hotel de Ville.

Consignments of mechanical limbs to Yankeeland form a most imposing item in French shipments to New York. The *Courrier des Etats Unis* notices the brisk sale of human joints, quite outrunning the supply, legs and arms being in particular request, and neatly turned crutches of every pattern being quite at a premium. In the assortment of limbs shippers are put in possession of a very remarkable statistical result. There are, on an average, eight *left* arms and *left* legs required for every *one* of the opposite category; and fighting men may at once account for that fact by the assault of the foe taking effect on the left side, where the right hand of the assailant must be always the most effective.

Encouraging accounts have been received by the Cotton Plantation Company of Natal from their manager in that colony, with two samples of cotton, described and valued by Mr. Pitcairn Campbell, of Liverpool, one as "equal in all respects" to "Good Sea Island," worth 50d. per lb., and the other capable of competing with "Middling Orleans," valued at 27½d. per lb. Under date of July 30, the manager adds that, with the company's own and those employed by contract, there would shortly be at least fifteen ploughs at work; that, what with Caffres, northern Zulus and Coolies, there was no want of labour; and that, with a large area progressively under cultivation, the produce would be on its way to England in July next year.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 622, 635, 637, 668, 669.
BOILERS AND FURNACES, 634, 645, 652.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 627, 643, 650, 651, 656.
SHIPS AND BOATS, including their fittings, 641, 665.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 620, 630.

Food and Beverages, including apparatus for preparing food for men and animals, 648, 667.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 616, 618, 623, 629, 649, 654, 658, 659.
Buildings and Building Materials, 624, 647, 657, 666.
Lighting, Heating, and Ventilating, 626, 632, 638, 663, 664.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 617, 619, 621, 636, 639, 642, 661.
Metals, including apparatus for their manufacture, 625, 640, 644, 646.
Chemistry and Photography, 660.
Electrical Apparatus, 633, 662.
Warfare, 628, 655.
Letter-Press Printing—*none*.
Miscellaneous, 612, 613, 615, 631, 653, 670.

612. W. Hamilton. *Improvements in means or apparatus for registering, suitable for advertisers' purposes.* Dated March 4, 1863.

This invention consists in arranging and printing, or otherwise exhibiting on board or other surface, the names and titles of the several newspapers or other media for advertising in alphabetical or other order. In juxtaposition to each of these names (it may be in the margin of the board or placard), a series of concentric discs or rings is placed, one of which is inscribed on the surface, and is stationary; the other rotates on an axis. On the stationary ones are inscribed the months of the year, and on each of two inner circles are inscribed numerals corresponding to the days of the month, as in an ordinary calendar, and each reading to 31. On another and inner disc are inscribed the numbers of insertions for advertisements, such as 6, 13, 26, 52, and others. This again is covered by another disc, having a notch cut in it to expose only one number at a time. On the central axis are disposed two hands, like the hands of a clock, or they may project from intermediate axes placed on the same axis. In ordering insertions of advertisements the one hand is turned to the month and date of giving the order or first insertion, and the other is turned to the month and date of expiring or last insertion opposite to each, and all of the names of the papers for which the advertisement is given, and the numbers of insertions at same time exhibited, thus will be seen at a glance the several conditions of all advertisements. *Patent abandoned.*

613. J. Craig. *Improvements in apparatus for detecting and detaining thieves, and indicating the presence of fire.* Dated March 4, 1863.

This invention relates to a peculiar arrangement and combination of apparatus governed by an electric current for detecting the fraudulent tampering with safe or other doors, and for detaining the person so engaged, part of which apparatus also serves as an indicator of fire. *Patent abandoned.*

615. W. Whittle. *Improvements in machinery for the manufacture of nails.* Dated March 5, 1863.

This invention consists—1, of improvements in machinery for heading portions of slit or drawn rods, strips, or wire. In this machine the rods are fed into the machine by a pair of rolls to which an intermittent motion is given by a pull and ratchet wheel worked from the main shaft. The rod fed into the machine is held by a pair of dies, by the motion of which a piece of the required length is cut off against a fixed cutting tool. A heading die advancing against the end of the rod compresses the said end and forms a head. The holding dies ascend with the headed blank in them, and the said dies opening the rod fed into the machine pushes the headed blank from the machine. The feeding rolls and holding dies give a more or less cylindrical figure to the rods or strips when the said rods or strips are angular in cross section. The invention consists—2, of improvements in machinery for grinding points on blanks made by a specially constructed heading machine, or by other heading machines. *Patent completed.*

616. T., E., and R. Thornton. *Improvements in machinery or apparatus for preparing wool or other fibrous substances for spinning.* Dated March 5, 1863.

The first part of this invention consists in having the machine called a "scribbler" provided with cards, similar to the carding engine, so as to produce cardings therefrom; also in the application thereto of ordinary piecing apparatus, so arranged that the cardings may be delivered or fed thereby to the creeper or feed apron of the carding engine; and also in giving a traverse movement to the apparatus employed for tipping the troughs of the piecing apparatus, so as to equalize the feed, and thereby produce more even cardings. The second part of the invention relates to means or apparatus for producing a draught on the cardings as they issue from the piecing apparatus of the carding engine by which the ordinary machine called "billy" is superseded. The apparatus consists of a pair of fluted rollers geared together in a box which is mounted on axes in suitable bearings to allow it to rotate. The axes of the rollers are at right angles to the axes of the box. On one axis or end of the box is fixed a pulley, and on the other end is another pulley which is attached to a bevel wheel capable of running loose thereon. This bevel wheel gears into another bevel wheel fixed on the axis of one of the rollers. This apparatus is placed and arranged so that, whilst the rollers are drawing the cardings, they are also twisting the same, more or less, according as speed is given to the two pulleys by cords, straps, or gear. Nipping rollers are also employed for holding the cardings whilst being drawn. *Patent completed.*

617. J. Clinton. *Improvements in the construction of flutes.* Dated March 5, 1863.

This invention is not described apart from the drawings. *Patent completed.*

618. W. Allen and W. Johnson. *Certain improvements in machinery or apparatus for grinding "cards" employed in carding engines.* Dated March 5, 1863.

This invention relates to the small carding surfaces employed in carding engines generally attached to a continuous chain, and termed "flats," and is designed for the purpose of grinding the surface of such cards in an even and true concave form, or in any other form desired. The improvements consist in the novel employment and use of a guide or peculiar shaped groove to cause the flat to approach and recede from the grinding cylinder at certain intervals, so that such guide governs the superficial form into which the surface of the flat is ground. *Patent completed.*

619. R. D. Dwyer. *Certain improvements in springs to be employed in the manufacture of beds, seats, or for similar purposes, where an elastic surface is required.* Dated March 5, 1863.

This invention consists in the employment and use of two thin laths, bound together at or about the centre of their length by a band of tin, or other confining material, the extreme ends of such laths being forced and retained apart by wedges inserted between them near the central confining band. *Patent abandoned.*

620. E. P. Plenty and W. Pain. *An improved method of supporting screens and straw shakers, specially applicable to thrashing machines.* Dated March 5, 1863.

This invention consists in supporting screens and straw shakers upon springs rigidly fixed at one or both ends, in lieu of the vibrating rods heretofore employed for that purpose. *Patent abandoned.*

621. W. Wells. *Improvements in horse shoes, and in the method of fastening the same.* Dated March 6, 1863.

This invention consists in forming horse shoes without nail holes, and in fastening them to the hoofs of horses by means of two or four projections or hooks from the shoe, which projections or hooks are clamped by a band of iron, or by two bands of iron passing in front of the hoof; in some cases these bands may be tightened by a screw or clamp. *Patent abandoned.*

622. W. J. and R. Watkins. *Improvements in steam engines.* Dated March 5, 1863.

This invention relates, chiefly, to those forms of engines known as direct-acting engines, and whether such engines be vertical, horizontal, or inclined, and whether employed for marine or stationary purposes. Instead of employing a guide back and guides, or any of the usual methods of guiding and supporting the outer end of the piston rod at its junction with the connecting rod, and instead, also, of working a pump by a lever or from off the crank by an eccentric or other means of communicating motion, the patentees effect these two objects of guiding the piston rod and working the pump by placing the pump barrel with its longitudinal axis in or nearly in a line with the cylinder, and between the cylinder and the crank shaft; and they connect the pump plunger or piston to the piston rod, and the end of the connecting rod of the engine by a fork, or any other suitable means; thus the pump is worked direct, and forms also the guide for the piston rod. In condensing engines the air-pump is the pump employed in this manner. The piston or plunger of the pump is of a sufficient diameter to allow of a trunk large enough to permit of the connecting rod vibrating therein, and where the distance between the cylinder end and the crank shaft is limited, as is generally the case in marine engines, they prefer to employ a single-acting and single-trunk pump, the capacity of the pump chamber or barrel being regulated by the dimensions of the annular space, or the difference between the exterior diameter of the trunk and the interior diameter of the pump barrel. In inverted direct-acting screw engines the valves may be placed at the bottom of each pump, in direct communication with the condenser. In every case the connecting rod works within the trunk of a pump placed between the cylinder and the crank, and the cylinder of the pump and the packed end or ends thereof; or the piston and the gland alone are the means of guiding the piston rod, and of taking the thrust due to the angular motion of the connecting rod. For working the back slide or cut-off slide of double slide valve engines, they connect such slide valve to the backward eccentric or its rod directly through a weigh shaft, or by any other of the well-known means, and they regulate the amount of expansion by changing the positions of the slides by means of a screwed valve rod, or other suitable means. *Patent completed.*

623. S. H. Foster, S. Bunney, and J. Anderson. *Improvements in means or apparatus for the manufacture of looped fabrics.* Dated March 5, 1863.

These improvements have for their object to obtain increased facility in the manufacture of what is commonly called "twined work" or "purl work," and rib work, when required. For this purpose, according to the first part of the improvements, the needles are arranged in two sets, and are capable of being separately acted upon in concentric rings. The needles of one ring are arranged radially, and the needles of the other ring are at right angles to them; or they may be inclined thereto. These needles have loose tumblers of the character of those known as Townsend and Moulden's needles, and for which letters patent were granted to M. Townsend and D. Moulden, Feb. 13, 1849 (No. 12,474), and they have short or hooked barbs; and attached to or moving with each of them there is also a spring or pointed instrument, the point of which is curved to enter a recess in the side of its needle, and at a short distance behind the point of this additional instrument there is also a projection or stop. By these means the loops formed on one set of needles may rest on the needles and pointed instruments referred to, and be held there whilst the needles of the other set enter between such pointed instruments and their needles for change of loop. In this adaptation, when it is intended to change from ribbed work to purl work, or purl to ribbed work, the tip of the incline or cam which gives motion to the needles will be raised or depressed at pleasure by means of a jacquard or other suitable selecting means. According to another modification, constituting the second part of the improvements, the needles are arranged in two cylinders, one over the other, and parallel to the axis of such cylinder, with the needles of one cylinder pointing in a direction towards those of the other. These needles also have loose tumblers, and those in the lower cylinder have the upper surfaces of their beards or barbs formed with recesses to receive the ends of the upper needles, whilst in the under side of each of the upper needles there is a recess to receive the point of a lower needle. Threads for loops may be laid on either set of needles as required, and the work is changed from one to the other set of needles by suitable guides. *Patent completed.*

624. J. Miller. *Improvements in horticultural buildings and other glazed structures, part of which improvements are also applicable to ventilating other buildings.* Dated March 5, 1863.

For the purposes of this invention, the heads and sills of the side and end frames are connected together by metal bands or angle iron, and the uprights or mullions are tenoned to these frames; and when either the side or end frames are of considerable length the patentee sometimes forms them in separate parts or sections by dividing them vertically through some of the vertical portions or mullions, and then connecting such divided parts by screws, so that they may be readily separated and reconnected when required. To give strength and stability to such structures, he applies cross stays of iron or wood from the mullions of one side to those of the other, connected by wood screws. The side or end sashes, in place of being hung, are formed in two sets to slide one over or to pass one in front of the other on metal ridges, which are perforated to admit of water collecting between them freely passing away. The overlapping portions, when the sashes are closed, lie behind the uprights or mullions. He also forms the roof in similar parts or sections by division of the main beams, which are in this case attached to the glazed frames. He also, for a span roof, employs two ridge pieces with a space between them for the free passage of air, and he connects these together at intervals. Over these connections, and between the ridge pieces, he applies a stationary plate or board with perforations at intervals, and over this he applies another plate or board, also perforated, and capable of being slidden, so that either the perforated or the plain portions of this sliding-plate or board may come over the perforations of the stationary plate or board. The sliding-plate or board is moved by a lever or other suitable means, and, if desired, there may be two or more of them. Over such perforated plates or boards, and the ridge pieces between which they are placed, and somewhat above them, supported at intervals so as to admit of ventilation, he applies a narrow span roof. *Patent completed.*

625. E. B. Wilson. *An improvement or improvements in the manufacture of steel, and in the apparatus employed therein.* Dated March 5, 1863.

We cannot here give space to the details of this invention. *Patent abandoned.*

626. T. W. Osborne. *Certain improvements in lamps.* Dated March 5, 1863.

This invention relates to what may be termed hand-lamps, and has for its object—1, to greatly improve the light, and so construct the reservoir that the light shall not be flooded, and thereby extinguished with any undulating or violent motion imparted to the lamp. This the inventor effects by surrounding that part of the wickholder that dips into the oil reservoir with a perforated or woven metal or other ring or tube to break the force of the oil in the body of the lamp when shaken, so that the oil immediately connected with the wick is not disturbed, and, consequently, the light is not flooded, and the oil being supplied by capillary attraction, the light is always brilliant. 2, The object of the invention is to render the working of the lamp, such as the opening and shutting of the door, its attachment to the belt, the removal of the reservoir for dressing and replenishing, as well as the removing and fixing of the screen and ventilator, more simple than the mode hitherto adopted, enabling the user to manipulate his lamp with more facility than such kind of lamps can now be used, and, by providing a lock motion to combine the top and body of the lamp together, prevent the possibility of a mischievous individual extinguishing the light by removing the top or ventilator, and thereby exposing the frame. *Patent abandoned.*

627. J. Howie. *Improvements in the construction of the crossings of railways.* Dated March 5, 1863.

Under one modification or system of arrangement embodied in this invention, in place of laying down rails of the ordinary kind 15 ft. or 16 ft. in length, short lengths of rails are inserted in the main and siding rails at the parts which are found to wear away most rapidly by the traffic of the carriages. The parts which are found to give way so much sooner than the other portions of the line, are those which are contiguous to the tongue or point rails of the crossings. At these parts a comparatively short length of rail is interposed between the line of the ordinary rails, and forming a continuation of the same. These short lengths of rail are, by preference, formed of steel, or case-hardened iron, in order that they may wear as long as the rails which are subjected to the ordinary wear and tear of the line. These short lengths of rail are fastened by means of fish-plates extending for some distance beyond the abutting ends of the rails, and are firmly bolted together. A portion of the bolts may be passed through both the rails, so as to obtain a very firm junction, and prevent all rocking or lateral motion of the rails. The fastening of the parts may, however, be effected in various ways. In conjunction with these short lengths of hard metal rails, it is proposed to make the extremities of the tongue rails in short pieces, fastened by suitable chairs, and extending backwards a length of 4 ft. or 5 ft., and made by preference of steel, or of case-hardened iron, so that these parts may wear in unison with the contiguous hard metal rails. Another mode of arranging the short rails is to form them in two parts, the lower portion of the rail being formed with a vertical web or feather, and the other half being of a saddle-like figure with a recess corresponding to the said mid-feather of the lower part. The upper portion of the rail is slipped on to the lower one,

and the two are firmly secured by being bolted together by the fish-joints. This arrangement admits of the upper portion of the rail being easily renewed from time to time when worn. *Patent completed.*

628. W. Clark. *Improvements in firearms.* (A communication.) Dated March 5, 1863.

This invention relates to an improved revolver pistol which may be divided into four principal parts—1, the barrel, which is slightly rifled, slides on a rod or axis at the under part, to which it is fixed by means of an eccentric; 2, a cylindrical breech; 3, a rotating breech-chamber, intended to receive the projectiles partially fitting in a case enclosing its rear end, and which protects the fulminating points; and, lastly, the stock, which contains the actuating mechanism, and carries the iron pin or axis before mentioned, serving to connect the principal parts together, and an eccentric groove for connecting the barrel thereto. The butt has a ring for attaching the pistol to the body, while the action is double, and is effected simply by cocking the hammer and then pressing the finger on the trigger. The two principal parts may be detached or connected together by hand by means of a simple arrangement, and without the aid of any instrument. *Patent completed.*

629. J. Elsey. *Improved apparatus for the winding of lace on to the work roller in warp lace, bobbin net, or twist lace machines.* Dated March 5, 1863.

This invention relates to apparatus for the winding of lace on to the work roller in warp lace, bobbin net, or twist lace machines. Heretofore, in such machines, as the diameter of the roll of lace or fabric wound on the work roller progressively increased, what is called the "take-up" of the work also increased, so that the end of the lace last made was longer than the portion first made, although there was an equal number of motions at each end. By means of this improved apparatus the lace or fabric is wound on the work roller as fast as produced on the machine, and at a certain and regular speed, whereby the lace or fabric is of the same length throughout, and without variation in respect of the tightness or slackness of the lace or fabric when made. *Patent completed.*

630. C. Clay. *Improvements in chain harrows.* Dated March 5, 1863.

In constructing chain harrows according to this invention, each row of links which passes transversely across the harrow is composed of alternate links of cast iron, or malleable cast iron, and of wrought-iron links, which connect together the links of moveable cast iron. The cast links are made with holes—by preference oval-shaped holes—through them on two opposite sides of the link, and the wrought-iron links pass through these holes. The wrought-iron links are, by preference, formed with notches on their opposite sides, into which notches the cast links fit; the wrought-iron links will thus always keep the cast-iron links at the proper distance apart, so that each row of links may be kept properly extended. The rows of links are connected together by the wrought-iron links of each row being connected to the wrought-iron links of the next row, either by plain links or wrought iron, or by links formed with holes through them on two opposite sides, as described. The chain harrow is connected to its whipple-tree by rods or chains passing from the whipple-tree to the wrought-iron links of the front row of links of the harrow. *Patent abandoned.*

631. J. Morris and T. Newton. *An improvement or improvements in refrigerators and other like articles.* Dated March 5, 1863.

The top of this improved refrigerator is divided into three compartments, that in the centre being intended for the ice well, and those at the sides to contain wine, water, or other liquid to be cooled, to which cooler taps are applied. The waste water from the ice well is conveyed to a cistern beneath another ice well at the bottom of the refrigerator by means of wide, flat, or other suitably-shaped channels formed in the back and sides. The top, sides, and back are packed with a packing consisting of burnt cork, charcoal dust, or other like suitable material. The rim of the lid when closed falls into a small channel filled with water, which keeps the ice well air-tight. A lower ice well extends over the whole bottom of the refrigerator, from which the waste water is conveyed to the cistern immediately beneath, from which it is withdrawn by means of a tap. By forming the channels for conveying the waste water from the upper ice well in the back and sides, and having an ice well at the bottom, the usual central division is entirely dispensed with, thereby obtaining increased space in the interior thereof, and effecting a saving of at least 100 per cent. in the consumption of ice. The patentees make the ice chests, refrigerators, and other like articles portable, and of any size or shape, and entirely of zinc, galvanized iron, or other suitable metals, thereby dispensing with the wooden casing as at present used, and which is well known not only to attract the heat but to retain it. *Patent completed.*

632. W. H. Buckland. *Improvements in the mode of, and in the apparatus for, producing gas for illuminating and heating purposes, parts of which improvements are also applicable for increasing the illuminating and heating power of ordinary lighting gas.* Dated March 5, 1863.

This invention consists in carburetting air or gas by causing it to pass over the surface or through woven fabrics or fibrous or spongy substances which have the property of sucking up and exposing the liquid hydro-carbon in a finely divided state. *Patent completed.*

633. M. Jourdin. *Improvements in machinery for engraving by means of electricity.* Dated March 6, 1863.

This invention is carried out as follows:—The pattern intended to be reproduced is first engraved by hand, or by any other process, at least four times larger than the engraved plate required. This pattern plate is fitted up with an insulating material, and it is adjusted on a frame connected with the machine. In front of this plate, thus prepared and adjusted to the frame, is placed a small metallic point, made slightly to press upon it, and in communication with one of the poles of an electric battery. On another frame is adjusted the metallic plate, or any other object to be engraved, such as watch cases, dials, jewellery, or other articles. In front of this is placed a small graver, pressing on the article to be engraved, or being pulled from it, through the medium of an electric magnet. Both of these frames are always turning during the operation; but the metallic point in front of the pattern frame and the graver in front of the other frame are both susceptible of moving in a longitudinal direction, but do not advance with the same speed, their speed depending on the relation between the size of the pattern plate and the plate to be engraved. This motion is obtained by the use of two wheels placed, the one with the slide supporting the point in front of the pattern, the other with the slide supporting the reproducing graver. *Patent abandoned.*

634. A. Cuthell. *Improvements in self-acting dampers for steam-engine furnaces.* Dated March 6, 1863.

This invention consists in certain arrangements of mechanism whereby the dampers of steam-engine furnaces are actuated and regulated in a self-acting manner, and constituting an improvement upon what is generally known as the cylinder and lever principle. In carrying the invention into effect, an equilibrium valve is placed in any convenient position between the boiler and cylinder, the same being in connection with the steam pipe, and capable of being adjusted to any required pressure by means of springs or weights. A piston working in a cylinder, or some other analogous contrivance, is employed, the water being placed so as effectually to close the communication between the boiler and the last-mentioned cylinder and piston until the pressure of the steam in the boiler is above that at which the valve has been adjusted. The damper is connected with the piston by means of suitable rods or gearing, such as will be well understood by persons conversant with the construction of steam machinery. Upon the pressure of the steam in the boiler overcoming the resistance of the valve, the latter is actuated, and the steam, being allowed to enter the before-mentioned cylinder, the piston consequently rises, and the damper is lowered by the upward motion of the piston. The valve being upon the equilibrium principle, is not affected by the pressure of the steam in the contrary direction after passing it, and the valve will, consequently, act freely under any variation of pressure in the boiler. The escape of steam from the cylinder may be effected by the action of the valve in shutting off the communication between the boiler and the cylinder, or by a small aperture at the bottom of the cylinder, so constructed as to let off the steam gradually, and which aperture may be kept constantly open. *Patent completed.*

635. A. W. Makinson. *Improvements in locomotive and stationary engines.* Dated March 6, 1863.

This invention is an improvement on a patent granted to the present patentee, dated June 17, 1862 (No. 1789), in which he described the end of the connecting rod as describing an ellipse round the driving axle, instead of a circle, by being attached to a pin working in a slot in the crank arm, which pin had its motion in the slot regulated or constrained by guides. He now finds that, by lengthening the connecting rod so as to extend beyond the driving wheel, and attaching it to a disc or crank arm revolving on a stud, or in bearings fixed in any convenient part of the frame, he can secure the motion of the crank pin of the driving axle in an ellipse in a more simple and efficient manner than by the use of guides. *Patent completed.*

636. A. Wilson. *The better and more commodious manufacture of all kinds of easy, lounging, and invalid chairs, seats, or settees.* Dated March 6, 1863.

This invention consists in the application of hammered or tempered steel, iron, vulcanized india rubber, or any other kind of accumulative spring or springs, that may be placed or fixed in or upon such parts or positions as may be best suited to the forms and fashions of the various chairs, chaises, seats, or settees that may be desired or sought to be accumulative, elastic, self-acting, and self-recovering. *Patent completed.*

637. W. E. Gedge. *Improvements in steam engines.* (A communication.) Dated March 6, 1863.

This invention is not described apart from the drawings. *Patent completed.*

638. G. T. Bousfield. *Improvements in the manufacture of illuminating gas, and in apparatus employed therein.* (A communication.) Dated March 6, 1863.

The first part of this invention consists in the process of decomposing the fluid hydro-carbons (whether fluid at the ordinary temperatures, or rendered fluid by preliminary heating or solution in a liquid hydro-carbon) in the presence of hydrogen previously prepared for the purpose, the hydrogen being supplied in the proper relative quantity to combine to form olefiant gas with the products of the decomposition of the hydro-carbons. The second part of the invention consists in an apparatus for performing the above process, which apparatus consists, substantially, of the combination of the following devices, viz.—1, a retort in which water is decomposed to furnish hydrogen; 2, a retort in which a fluid hydro-carbon is decomposed by heat; 3, one or more furnaces for heating the retorts to the required temperatures; 4, apparatus to supply water in regulated quantities to the retort in which it is decomposed, whether such water be supplied in liquid form or in the form of steam; 5, apparatus to supply a fluid hydro-carbon in regulated quantities to the retort in which it is decomposed; 6, a connecting pipe to conduct the hydrogen from the retort in which it is formed to the retort in which the fluid hydro-carbon is decomposed. The third part of the invention consists in the employment of zinc in the retort in which water is to be decomposed, in connection with the second part of the invention, so that the oxygen of the water shall combine with the zinc to form an oxide of zinc, and that illuminating gas and oxide of zinc shall be products of the operation. The fourth part of the invention consists in the combination of the retort for the decomposition of water with the retort for the formation of the illuminating gas through the intervention of a condenser, so that such zinc or other substance as may pass off with the hydrogen may be separated from it previous to the introduction of the hydrogen into the retort in which the formation of illuminating gas is to take place. The fifth part of the invention consists in the combination of a heating apparatus with the second part of the invention for the purpose of heating steam previous to its decomposition. The sixth part of the invention consists in the combination of a heating apparatus with the second part of the invention for the purpose of reheating the hydrogen previous to its introduction into the retort in which the illuminating gas is to be formed. *Patent completed.*

639. D. W. Ransom. *Improvements in fixing artificial teeth.* Dated March 6, 1863.

This invention is applicable when fixing teeth in vulcanite or like mounted bases. Artificial teeth have before been made with metal pins, which have usually been bent in opposite directions, in order that when the base of vulcanite or other suitably formed base has been constructed and rendered hard, the teeth may be held securely to the base. This mode of applying pins has not, however, been free from objection. According to this invention, the patentee forms the pins, or it may be a single pin, with a screw thread or threads thereon, or with notches; if two or more pins are applied to a tooth, they may be arranged parallel to each other, but he prefers that they should incline away from each other. *Patent completed.*

640. T. Hancock. *An improved receptacle for gold and silver or other coins.* Dated March 6, 1863.

This improved receptacle may be made in the form of a cash box or other form, and consists of two halves or parts, the line of the junction of which lies across the centre of the coins to be deposited therein. Each such half or part of the receptacle is divided into any number of divisions, in such manner that one or more of such divisions, say, the divisions in the lower half or part, is of such a length that each division may contain a desired number of sovereigns, or other coins, say, by way of example, 5 sovereigns or a proportionate number of half-sovereigns or other coins; a number of other divisions are of such length that 10, 15, 20, or other required or determined number of coins may be put in each such division, which said divisions the patentee sometimes provides with a metal, india-rubber, or other spring. These divisions are of precisely such length that only the intended number of coins can be placed therein. There are also other divisions for receiving loose coins or uncounted change; and in order that the divisions may allow of new or old coins being placed within them, an end of each division or separate compartment may be slightly moveable endwise, but only to the extent of the difference that may exist between, 5, 10, 15, 20, or any other number of new, old, or worn coins. Between the moveable end of one division or separate compartment and the fixed end of the next compartment he places a metal, india-rubber, or other spring. He makes the whole receptacle of wood, metal, papier mache, or other convenient material. When the upper part or half of the receptacle is closed down upon the lower half or part, and secured thereto by locking or otherwise, none of the coins therein (except the loose change or uncounted coins in their division or compartment before mentioned) can be shaken loose or displaced, the upper half of the receptacle being an exact counterpart of the lower end. *Patent completed.*

641. H. R. Spicer. *Improvements in protecting and preserving the bottoms and sides of ships and other submerged surfaces from oxidation or fouling by incrustation, the attachment of barnacles, the action of animalculæ, or from any other like causes of injury.* Dated March 6, 1863.

For the purposes of this invention, the inventor employs sheets, plates, or tiles of glass, china, or porcelain, of such size and thickness as may be most suitable to the surface to be covered. He attaches the said sheets, plates, or tiles of glass, china, or porcelain, to the surfaces to be covered by cementing mediums, such as red lead, putty, bituminous or resinous cements, or mechanical means, such as screws, nails, or pegs formed partly or entirely of metal or glass, or by the employment of flanges, dogs, or clips formed by the configuration of the said sheets, plates, or tiles. *Patent abandoned.*

642. T. G. Webb. *Improvements in the manufacture of articles of pressed glass.* Dated March 6, 1863.

This invention relates to those articles of compressed glass which are provided with handles, such as custard cups, and a variety of others, and consists in forming such handles (which are usually hollow) with a mid-feather uniting the outward part of the handle to the body of the article. By this means the patentee is enabled to secure greater strength, and to avoid that roughness which exists in such handles made after the ordinary manner, and without losing the appearance of lightness existing in hollow handles. *Patent abandoned.*

643. A. V. Newton. *An improved construction of elastic carriage wheel.* (A communication.) Dated March 6, 1863.

The patentee claims rendering a carriage wheel elastic by making the felloe in two concentric parts, and interposing a belt or layer of india rubber or other elastic material substantially, as described. *Patent completed.*

644. W. E. Newton. *Improvements in the construction of metal casks, and in the machinery employed in the manufacture thereof.* (A communication.) Dated March 6, 1863.

This invention consists in the manufacture of such casks of sheet iron, and of cylindrical form, having their external convex surfaces formed with circumferential corrugations, extending in a continuous series from one chine thereof to the other, in such a manner that the salient corrugations of one cask shall fit the re-entering corrugations of another of the same pattern arranged side by side with and close to it, so that a rank or tier of such casks shall interlock firmly with each other, and pack closely together, and so facilitate their stowage on board ship or elsewhere. The invention further consists in the insertion within a cask, having its exterior formed of sheet metal, corrugated as above specified, of a plain internal or lining cylinder, made to fit snugly and tightly to the internal cylinder, and secured thereto at the chine. Also in the manufacture of a cask of sheet metal

with its heads sufficiently concave externally, and convex internally, to prevent them from being bent outward by the internal pressure of the fluid that may be contained therein, and with flanges bent at nearly right angles to their respective surfaces, and so shaped as to be readily fitted and rivetted, or otherwise secured, to the chines of the cask. The invention further consists in the construction of the head of a sheet-metal cask of the flanged concavo-convex form above specified, of a diameter larger than the interior of the chine of the cask, and in combination with this a groove or corrugation is made in the chine, so that when the head is sprung into the cask, it shall find a firm shoulder, and make a closer joint when any pressure is brought against its interior. Another improvement consists in strengthening the chines of sheet-metal casks by shrinking metal hoops upon their exteriors, such hoops, by being rivetted through the chines, also aiding to secure the heads in their place. Another improvement consists in the use of a double hoop, so constructed and applied as to lap over the chine of a sheet-metal cask, and surround the exterior of the chine, as well as to line the flange of the head. These metal hoops are rivetted through the chine and flange, thus serving both to strengthen the chine and to aid in securing the head. The construction of the bung-hole constitutes the next improvement as applied to a cylindrical corrugated cask, with inside and outside supporting rings or cheeks fitted to the corrugations of the body of the cask, and attached together by bolts or otherwise. The bung of the cylindrical sheet-metal cask having its bung-hole in its perispherical surface, is so constructed that it will be somewhat depressed beneath the outside supporting ring or cheeks surrounding the hole, and be thereby protected by such ring or cheeks when the cask is rolled over an even surface. *Patent completed.*

645. H. Whittles. *Improvements in machinery and apparatus for collecting the condensed steam or waste water from places where steam is used, and returning the same to the boiler.* Dated March 9, 1863.

In carrying out this invention, the inventor causes the waste steam to be passed through one or more pipes (and valves adapted to the pressure) to a compound box or chamber, having in it a float attached by a rod and chain or cord to a balance wheel, to which is fixed one or more pins or tumblers. The top of the compound box is connected by a pipe with the steam part of the boiler, and the pipe is provided with a tap for opening and closing the communication, which tap is connected to a lever in contact with another lever, capable of being acted upon by the pins or tumblers on the balance wheel. At the bottom of the compound box there is a pipe and valve communicating with the lower part of the boiler. As the water from the waste steam collects in the compound box, the float rises and turns the balance wheel, which causes one of the pins or tumblers to act upon the levers, and open the tap in the upper part, and form a communication between the boiler and compound box, and allow steam from the boiler to press upon the water collected in the compound box, and force it through the lower pipe into the lower part of the boiler, and thereby empty the contents of the box into the boiler. *Patent abandoned.*

646. R. Mushet. *An improvement in the manufacture or treatment of pig or cast iron.* Dated March 9, 1863.

The essence of this invention consists in mixing and combining with melted pig or cast iron, which it is intended to form into castings, a quantity of melted steel, semi-steel, or malleable iron, which said melted steel, semi-steel, or malleable iron has been obtained by refining or decarbonizing melted pig or cast iron by the pneumatic process, or melted steel, semi-steel, or melted malleable iron prepared by processes other than the pneumatic, in order by this admixture and combination to strengthen and improve the quality of the said pig iron or cast iron.

647. J. Cowley. *Improvements in machinery or apparatus for manufacturing bricks, tiles, pipes, and mouldings.* Dated March 9, 1863.

This invention relates to a peculiar arrangement, construction, and combination of machinery or apparatus for moulded bricks, brick mouldings, perforated bricks, tiles, and drain pipes, whereby less power is required to actuate the machine, and a smaller proportion of water employed than in the ordinary methods of brick making. According to this invention, a hopper and pug mill, with a receiving box and piston, are employed in combination with a mould box, which is also provided with a piston of its own. The clay, which may be taken direct from the bank, is placed in the hopper and prepared and well worked by the knives of the pug mill, which also force it down into the receiving box, from whence it is forced by a piston or plunger into the mould. If a perforated or partially perforated or recessed brick is required, this mould box is provided with cores of greater or less length to produce the perforations or indentations intended to be produced. From this mould the brick thus moulded and pressed is expelled by piston working therein, and is received on to an endless travelling web which carries it clear of the machine. In making tiles and pipes the brick mould is removed and replaced by the required mould or die to suit the article to be manufactured. *Patent completed.*

648. H. A. Bonneville. *A new aromatic vinegar for removing stains from cloth and other materials.* (A communication.) Dated March 9, 1863.

The patentee claims the use of the ethers, amyl-acetic, ethyl-acetic, and methyl-acetic, as base of a new aromatic, and at the same time, hygienic vinegar, which may be used for removing stains from stuffs of all kinds, without altering their shades, whether employed alone or mixed together in equal parts, dissolved or not dissolved, in absolute alcohol acidulated with acetic acid for the purpose of reviving certain colours, or aromatized by the addition of certain perfumes. *Patent completed.*

649. J. Isherwood. *Improvements in working presses for making up yarn in bundles.* Dated March 9, 1863.

This invention consists in giving the requisite pressure to the yarn by the direct action of hydraulic power or steam. In performing the invention, a ram is attached to the follower of the press, and this ram fits in a cylinder in communication with the water or steam pipe, which is furnished with inlet and outlet valves, either in equilibrium or otherwise. When the yarn to be pressed is placed on the follower, and the top and sides of the press are secured in the usual manner, water or steam is admitted to the cylinder, and the follower is gradually raised until the yarn is sufficiently compressed; a self-acting or other stop connected with the follower then comes into operation, and by closing the inlet valve shuts off the water or steam by which the follower is raised. The bundle of yarn is then corded in the usual manner, and the outlet valve is opened to allow the follower to descend for the subsequent operation. *Patent completed.*

650. J. Haworth. *Improvements in breaks for omnibuses and other carriages.* Dated March 9, 1863.

This invention consists in applying a metal clip lined with leather or other suitable material for increasing the friction to the nave of one or more of the wheels of an omnibus or other carriage, and in connecting the two ends of the clip to a double lever which is in communication with a treadle or handle. *Patent abandoned.*

651. C. H. Lea. *Improved apparatus for opening and closing the gates of railway crossings, which apparatus also acts simultaneously upon the signals.* Dated March 9, 1863.

This invention is designed for the purpose of preventing accidents at level crossings, and to enable one person by a simple movement of a lever to open or close both gates, and at the same time to set the signals on both the up and down lines of the railway. At places where a railway crosses a common road at about right angles, it is usual to have two pairs of gates, so arranged as that when they are open as regards the road, they are closed as regards the railway, and *vice versa.* The patentee mounts these gates so as to turn upon footsteps, and connects each gate by a link to the outer end of a lever capable of vibrating on a fixed centre. The inner ends of each pair of levers meet in the centre, and are furnished with slotted eyes, and they are all four connected together by rods and links running along the six foot way, so that they must all act simultaneously. The outer end of one of the levers is lengthened, and is connected by a chain or chains to two hand levers, one of which being depressed causes the gates to open simultaneously, and the other closes them in a similar manner. By connecting the ordinary semaphore or other signals on the up and down lines which work the gates by means of chains passing round pulleys, the opening of the gates (or closing of them as regards the railway) will be caused to raise the danger signals on both lines, a spring or weight bringing the same down as soon as released by the closing of the gates to the road. *Patent completed.*

652. W. Inglis. *Improvements in steam boilers and engines.* Dated March 9, 1863.

This invention is not described apart from the drawings. *Patent completed.*

653. P. Hugon. *Improved machinery for obtaining and applying motive power.* Dated March 9, 1863.

This invention is based upon the indirect action of an explosive mixture upon the piston of an engine by means of an intermediate column of water which is exhausted by the vacuum which the explosion produces in the generating tubes; the characteristic features of the invention are—1, the substitution of the indirect action of the exploded mixture for the direct action which takes place in ordinary gas engines; 2, the indrect action of the explosive power upon the piston rod, through an intermediate column of water, on the surface of which the mixture of air and gas is exploded; 3, the inflaming of the mixture of air and gas in a tube of the receiver separated from the engine cylinder; the vacuum produced in a space separated from the cylinder determines the to-and-fro movement of the piston; 4, the constant circulation of the same water in the machine; and 5, the presence of water in every part of the machine for the better utilization of the vacuum. *Patent completed.*

654. A. Keller. *An improved apparatus for reeling silk direct from cocoons or bobbins.* March 9, 1863.

For the purposes of this invention, an apparatus is combined in the following manner, and by preference each combined apparatus is arranged to reel with six sets of cocoons at the same time, but apparatus may be similarly arranged to reel with other number of sets of cocoons. The apparatus is further arranged in pairs, so that on the breaking of any of the fibres only one pair may be stopped in order to piece up the broken fibres. The cocoons are placed in a basin containing water, which is kept heated by a steam pipe. The desired number of filaments of silk, from as many cocoons, are compacted together by an apparatus as the filaments rise towards a reel, on to which the compacted filaments are continuously wound, so as to take some turns on the reel, and at the same time such compacted filaments are unwound or delivered from the reel to the cylinder, which is either of smaller diameter than the reel, or moving with a less surface speed, so as to allow the filaments of silk to shrink before they are wound on to a bobbin. The cylinder is placed within a case or chamber, which is supplied with heated or dry air, and there is a steam pipe within the chamber to heat the same. The bobbin on to which the compacted fibres are wound is in surface contact with the cylinder, and is caused to rotate thereby. The compacted filaments are spread evenly on the bobbin when being wound thereon. *Patent completed.*

655. W. J. Clapp and N. Coats. *Improved armour plates for vessels, turrets, targets, forts, and other structures in which armour plates are or may be used.* Dated March 9, 1863.

The patentees employ plates of iron, or other suitable metal, with curved and with flat portions, and through the flat portions they pass bolts or rivets to secure the same to the framing of the vessel, turret, target, fort, or structure, in such manner that other curved plates may be placed over the said flat portions of the first mentioned plates, and over the joints thereof, to cover and protect such bolts or rivets first mentioned, the last mentioned curved plates being bolted or rivetted through the first mentioned cor[illegible] plates, or otherwise, or secured in any equivalent manner. By these means additional strength is obtained, and the principal, and if desired, the major, part of the joints and bolts or rivet heads is protected, so that a single plate shall not receive all the force of any projectile or striking body, but such force be distributed over the whole of the plates, thereby rendering them impregnable if constructed of proper thickness. The plates should be produced by rolling or compressing. *Patent completed.*

656. J. R. Gorst. *Improvements in carriages.* March [illegible], 1863.

This invention has for its object the construction of carriages in such a manner as to facilitate their draft by the use of wheels of increased diameter, and to admit of the centre of gravity of the carriage being lower than usual. For this purpose the shank of the axletree is lengthened, as required, and is made to form (either with or without the aid of a pieced crank) a fixed vertical guide for a grooved slide, which carries a box in which the upper part of the said shank is enclosed, in such a manner as to give stability to the said shank, and prevent the box and slide from moving thereon in any but a vertical direction to an extent limited by the length of the slot in the box, and the fixed stops. The upper part of the shank of the axletree, where the axle is inserted, is strengthened by two side pieces, which fit the hollow space in the box, and are brought in contact with the said fixed stops as the box is pressed upwards to its extreme height by the springs, or downwards by the weight on the body of the carriage. At the lower end of the shank of the axletree there is a cross-piece or crutch, to which is or are fixed a spring or springs, and which extend to a corresponding cross-piece or crutch at the bottom of the shank on the opposite side of the carriage. This spring or springs is or are intended to take the smaller weight—that is to say, the weight of the unloaded carriage, and there are two side springs (one on each side of the carriage) fixed at their ends to the body of the carriage, and bolted in the middle to a cross-piece fixed on to the shank of the axletree, which springs are intended to take any greater weight put upon the carriage. Or there may be two springs on each side fixed between the bottom plate of the said box and the said cross-piece for the same purpose. *Patent completed.*

657. W. E. Newton. *Improvements in the construction or laying of wooden floors.* (A communication.) Dated March 9, 1863.

This invention relates to that description of floor in which pieces of wood of suitable shape, colours, or dimensions are arranged as a flooring in any convenient manner, to produce a kind of pattern or design. The invention consists of a cheap and novel mode of securing the pieces of wood. In carrying out the invention, the ground on which the floor is to be laid must be well rammed down and made quite flat. Laths or battens are then laid thereon at suitable distances apart, according to the circumstances of the case, the laths or battens being of course laid transversely to the direction in which the flooring boards are to be placed. The ground, with the laths or battens thereon, is then covered with a layer of hot bitumen, asphalte, or other suitable mastic or preparation, and then the pieces of wood which are to form the flooring are placed thereon with their edges well fitted together. In order to cause the pieces of the wood to be held securely, they should be grooved on their under sides, so that the softened bitumen or asphalto may enter therein, and hold them down firmly from behind. *Patent completed.*

658. J. H. Johnson. *Improvements in the treatment of certain fibrous vegetable substances with a view to the production of textile materials therefrom.* (A communication.) Dated March 9, 1863.

According to this invention, it is proposed to employ the fibres of the agave or aloe, layetta linteana, hemp, flax, sossage manilla, jute, and the fibrous portions of the wild pine-apple plant, and to treat them either separately or together in the following way:—The fibrous vegetable substances having been first dried, are then subjected to a macerating process under edge wheels, stones, or rollers, grooved or plain, in order to render the fibres soft and flexible. These fibres are then to be placed in a vat containing just sufficient hot water to cover them, and to 1,000 parts by weight of fibre are added 6 parts by weight of chloride of lime, or its equivalent proportion of bleaching liquid, or chloride of soda, and 6 parts by weight of sulphuric acid of commerce. The fibres are now allowed to macerate, the chemical action being assisted if desired by the application of heat. When the fibres are removed from the vat, care is to be taken to protect them as much as possible from contact with the atmosphere, and they are then washed either in running water, or in suitable vessels. The same chemical bath may be employed for more than one operation. Finally, the partially prepared fibres are dried, combed, and carded, and otherwise treated after the manner of treating cotton for the manufacture of textile fabrics. *Patent completed.*

659. H. Fletcher. *Improvements in cleaning and preparing cotton for spinning.* Dated March 11, 1863.

In carrying out this invention, the inventor makes a cotton gin suitable for poor emigrants, ryots, and small cultivators, by using a light iron stand cast in one piece (adapted to sewing machines, as described in the specification of patent 1784, dated August 2, 1859). He uses metal rollers and large gearing on both sides of the frame. An idle wheel on one side changes the direction, and gives increased speed, if used as a driver. An extra roller above and below the working rollers strengthens them. The same or a differential velocity is given to the rollers by the relative proportions of the gearing. Pressure is got by india-rubber weights, springs, or other means commonly used to obtain elastic force. Diaphragms above and below the rollers prevent overlapping and separate the fibre and seeds from the rollers. The fluted gearing of the Indian churka made of metal may be used instead of both sides gearing. He uses metal instead of leather for the rollers in the gins commonly called McCarthy gins. The light iron frame before referred to will do for these gins. *Patent abandoned.*

660. R. T. and R. MONTEITH. *Improvements in making dyes from aniline and its analogues.* (A communication.) Dated March 11, 1863.

This invention is carried out as follows:—Aniline red—a substance well known in commerce, and which is made from aniline or one of its analogues—is mixed with a dry salt of aniline, or one of its analogues, and heated in a suitable vessel, either hermetically closed, or not, to a temperature of 390 deg. Fahr., and upwards, for as long a time as may be necessary to form the dye of the required shade. This will be from one to six hours. The dyes thus produced are shades of brown called in France "Cairs" and "Havanne." The brown dye thus formed may be separated into two brown dyes of different shades, a part being soluble in boiling water, and nearly all the rest in alcohol. The mass which results from heating the aniline red and the dry salt of aniline must, therefore, be treated with a sufficient quantity of boiling water to dissolve out all that is soluble in it, and then filtered, and the residue treated with alcohol and filtered. Both filtrates will dry brown, but of different shades. These dyes may be used at once for dyeing textile fabrics and yarns, or they can be purified by any of the methods in general use for purifying aniline colours before dyeing with them. *Patent completed.*

661. F. COOKE. *Certain improvements in the manufacture of hats or coverings for the head.* Dated March 11, 1863.

This invention relates to the manufacture of such hats or coverings for the head as are made of felt or similar material, and also to the manufacture of that portion of hats called the hat body, which is generally composed of woven fabric and varnish, and subsequently covered with plush. The invention is designed to produce a sharp angular and well-defined edge at the junction of the crown with the sides, and consists in the employment and use of an india-rubber or other elastic "crown core," formed with an angle corresponding to the mould in which the hat is made. This core is fitted into the crown of the hat or body when in a pliable state, and pressure is applied thereto either by means of water, as at present used in making felt hats, or by other convenient means. By this pressure the india-rubber core is caused to expand and press the felt or other material into the angle of the exterior mould, and produce an angular junction between the sides and the crown of the hat, instead of such edge being rounded as hitherto. *Patent abandoned.*

662. R. A. BROOMAN. *Improvements in voltaic belts and bandages.* (A communication). Dated March 11, 1863.

This invention consists in constructing belts and bandages composed of a bi-metallic core, consisting of plates, strips, or blades of metal one electro-positive to the other, such as copper and zinc, forming a voltaic battery, juxtaposed or placed one against the other, and covered with some fabric or material which will keep them in place, and to which buckles, tapes, or other means of fastening are applied to secure them to any desired part of the body. The plates, strips, or blades may be of any form, according to the part to which they are to be applied. The moisture of the body will generally suffice to excite the bandages to action. In some cases, however, they may be excited b vinegar or diluted acid more or less strong. *Patent abandoned.*

663. J. CASSELL. *Improvements in moderator lamps to adapt them to the burning of petroleum and other mineral oils and hydro-carbons.* (A communication). Dated March 11, 1863.

This invention is not described apart from the drawings. *Patent completed.*

664. G. A. FULTON and J. CLYDE. *Improvements in dry gas meters.* Dated March 11, 1863.

The main object of this invention is to adapt dry gas meters to the foot or base of the pillars or columns of street lamps; and the invention consists in forming an inlet aperture in the bottom or lower part of the gas chamber, and in connecting the supply pipe directly therewith, so that the gas may enter at once into the gas chamber. The inventors form the outlet from the top and centre of the meter case. *Patent abandoned.*

665. W. R. MULLEY. *Improvements in sheathing iron ships, caissons, and other like structures.* Dated March 11, 1863.

This invention consists in attaching metal sheathing to iron ships' bottoms, caissons, and other like structures as hereafter described. The patentee takes two pieces of angle iron with J on one edge. He prefers the iron to be 3-16ths in. thick, angle flange ½ in. wide, the two T flanges together 1 in., so as to leave about ¼ in. in projection on each side. He places them vertically and parallel to each other about 18 in. apart on the ships' side. He then introduces a length of, say 1½ in. wood sheathing, between or immediately behind the frames, using a portion of their rivets to fasten them on, the grooves in the ends of which correspond with the projections of the T-flange formed to receive them. He fastens one of the irons by tap-screws or rivets. He then lays on the ship's skin hair and tar, or any other suitable composition, puts one end of the wood in its place, then brings the other iron against the other end always with the flange outwards, and so on throughout. The ends of the separate pieces of sheathing meeting on the tops of the irons, the whole presents a surface as upon a wooden ship. He then caulks it and covers it with pitch and felt, so as to render it perfectly impervious to water. *Patent completed.*

666. H. WILSON. *Improvements in machinery for shaping wood.* Dated March 11, 1863.

This invention consists in constructing machinery (the details of which we cannot quote here) whereby wood is shaped, either one piece or several pieces at one time, to the form of a metal or other suitable hard template or guide by means of rotating cutters which act upon the wood in the direction of the grain thereof, whereby a smooth and even surface is obtained. *Patent completed.*

667. W. WOOD. *Improvements in the manufacture and ornamentation of pomfret or liquorice cakes, rolls, sticks, and pipes, and other similar articles of confectionery.* Dated March 11, 1863.

The object of the first part of these improvements is to make pomfret or liquorice cakes, rolls, sticks, and pipes coloured, and of various colours, instead of making them black. The patentee effects this by the following methods:—By repeatedly working, rolling, and drawing out the boiled liquorice paste or mixture when in a nearly cold and stiff state the colour becomes lighter, and this effect is increased by altering the usual ingredients of the mixture. If the flour ordinarily used be omitted, and an additional quantity of sugar used in lieu of it, the colour becomes very much lighter. By manipulating the paste as before described, boiled sugar, if repeatedly pulled when nearly cold and stiff, becomes quite white, and so, even when black extract of liquorice is used, alters with the above-named treatment the colour of the whole mass to a pale brownish colour. If a light-coloured extract of liquorice be used, the colour of the paste will be much lighter; it is also desirable to use white refined sugar and gum. When preparing this article, the patentee, by preference, uses the heated table and rollers described in the specification of his patent No. 356, of the year 1862, together with the subsequent reducing and drawing-out rollers and cake-making roller machinery that is described therein. *Patent completed.*

668. A. BARCLAY. *Improvements in locomotive, boring, and winding engines.* Dated March 11, 1863.

This invention relates to the arrangement and construction of boring and winding engines, which are also arranged to be self-propelling. Under one modification, the boiler of the engine forms the framing, or it may be carried on a rectangular framing, in the ordinary way. The boiler is of the horizontal tubular class, and on the upper part is arranged a pair of standards, which carry a horizontal shaft forming the axis of a beam; one end of this beam is connected to the piston rods of a pair of vertical cylinders placed on the upper part of the boiler at one end. The other end of the beam overhangs the end of the engine, and to this free extremity are attached the boring rods and tool. A horizontal cylinder is arranged parallel with the boiler on each side. The piston rods of these cylinders are connected to a crank shaft extending across the boiler. A pinion on the crank shaft drives a spur wheel on a shaft fitted between the beam standards, and carrying the winding barrel. This pinion slides to and fro on a feather, so that the winding barrel may be readily thrown into or out of gear by means of a coupling and hand lever. The crank shaft also carries a pinion or spur wheel at each end, which gears with an annular wheel formed inside each of the main or driving wheels of the engine, so that by putting these pinions into gear with the bearing wheels the engine becomes a traction engine. The engine is guided from the rear by means of a hand wheel arranged on a horizontal shaft extending beneath the boiler. This shaft carries at its extremity a worm, which gears with a worm-wheel connected by a central T-shaped connecting piece to the axles of the trailing wheels. The details of the engine may be variously arranged; the winding barrels may be fitted at either end of the engine, and, if preferred, arranged lower down. The funnel may also be fitted to serve as the standard for carrying the overhanging beams. Another mode of fitting this engine is to drive the crank shaft from a pair of right-angled cylinders arranged at the side of the framing. The boiler is preferred to be of the vertical class, and the funnel serving as the beam standard. A pinion on the crank shaft gives motion to the winding barrel, and on the same shaft are pinions for driving the bearing wheels. This engine is guided by a hand-wheel and worm arrangement for turning the leading wheels. *Patent completed.*

669. A. BARCLAY. *Improvements in traction engines and in apparatus for indicating the pressure of steam.* Dated March 11, 1863.

This invention relates, in the first place, to certain improvements in the construction and arrangement of traction engines, which improvements are based upon an invention of a similar kind for which letters patent were granted to the present patentee, dated March 10, 1862 (No. 646). Under one modification of the present invention, as applied to traction engines of the right-angled class, the crank shaft of each pair of engines has its bearings at one end arranged in the side standard or frame, whilst the other end is connected to the main axle, or to the centre of the driving wheel, so that this end of the shaft vibrates with the motion of the spring of the driving wheel, whilst the other end remains a fixture in its bearing. The other pair of engines have their crank shaft arranged in like manner, the fixed bearings being on opposite sides of the machine. In this way the vibrating motion of the wheels, as they traverse over the inequalities of the road, is imparted to one extremity of each crank shaft, but without affecting the opposite ends, which revolve steadily in their bearings. The object of the arrangement is to prevent the vibration of the driving wheels from affecting the heat of the valves. The driving wheels are arranged—one with a long tubular axle to which the wheel is keyed, and extending across the framing; the other wheel is fitted with an axle which passes through the tubular one, and is fastened by a nut. Or the two axles may be arranged parallel to rotate in contact, and thus obtain an extended bearing surface when the engines are driven at different speeds. The traction engine is coupled to the vehicle accompanying it by a T-shaped connecting piece, which is carried in a vertical spindle, its prolongation passing through two bushes carried by the framing of the connecting carriages, the hind wheels of which are connected with the engine by means of a shaft and wheels, or by connecting rods direct, so as to angle along with the engine when going round a curve. This arrangement admits of the lateral and vertical improvements of the coupled engine and vehicle. The traction engine may also be guided as well as regulated in speed by means of a duplex break action, which is operated by a single hand lever, so that the motion may be checked or the break applied to either side of the machine, and so guide it by the different speeds of the driving wheels. The improved pressure gauge consists of a metal or other chamber formed in two parts, and divided by an elastic air-proof diaphragm. Above the chamber is fitted a graduated glass tube, partly filled with water, which rests on the elastic diaphragm. The pressure of the steam raises the diaphragm and column of water, causing the air to be compressed, and in the ordinary gauges the air escapes through the water when subjected to long continued pressure, but by interposing the diaphragm of elastic air-proof material this escape is prevented, and the gauge continues correct in its indications. *Patent completed.*

670. J. WERGE. *Improvements in apparatus for indicating any regulated maximum or minimum degree of temperature.* (A communication.) Dated March 11, 1863.

This invention relates to a peculiar construction and arrangement of apparatus in connection with an alarm for indicating any regulated or given maximum or minimum degree of temperature, and consists in the employment of a compound metallic strip fixed at one end to a connecting piece in communication with one of the poles of a galvanic battery, whilst its opposite end is free to move to or fro by the action of heat or cold upon the two metals composing the compound strip, as is well understood. In combination with this strip, there is an adjustable indicator or pointer turning upon a fixed centre, and capable of being adjusted to any degree of heat or cold upon a properly divided thermometrical scale. This indicator is in communication with an electric alarm, and through it with the opposite pole of the battery. So long as the end of the compound metallic strip remains out of contact with the indicator, no alarm will be given, but as soon as an undue elevation of the temperature takes place, the strip will be deflected, and will come in contact with the indicator, whereupon the electric circuit being established, the alarm bell will commence to ring, and will continue so to ring until the original temperature is restored again. By the combination of the index, arm, scale, and metallic strip with a battery alarm apparatus and key-board, notice can be given of any variation of temperature beyond the regulated limits taking place at any number of points more or less distant, and an indication given of the particular point where such variation has taken place. In indicating an excess of cold, the strip will require to be placed on the opposite side of the indicator to that on which it is placed when intended for indicating an excess of heat. By employing a double index, the instrument may be employed for giving an alarm in case of either an increase or diminution of temperature above or below certain limits capable of regulation at pleasure. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated August 7, 1863.

1950. F. G. Mulholland, 36, Essex-street, Strand, engineer. Improvements in pipe castings for gas, water, sanitary, and other general purposes, and the introduction of an elastic chemical compound to form expansive joints thereto for prevention of leakage.

Dated August 26, 1863.

2103. J. Thomas, mechanic, and W. F. Marshall, reed maker, Shipley, Yorkshire. Improvements in apparatus for spinning.

Dated August 31, 1863.

2152. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved machinery for sawing irregular forms of wood. (A communication.)

Dated September 17, 1863.

2285. J. G. Ulrich, 47, Wellclose-square, chronometer maker. Improvements in apparatus applied to railway carriages and trains in order to obtain greater safety to passengers.

Dated September 19, 1863.

2314. I. de Angelis, Naples, captain in the army. An improved apparatus for obtaining motive power. (A communication.)

Dated September 21, 1863.

2329. C. T. Burgess, 3, Upper Gower-street. Improvements in reaping machines.

Dated September 22, 1863.

2338. R. A. Brooman, 166, Fleet-street, patent agent. Certain compositions for preserving cheese. (A communication.)

Dated September 24, 1863.

2350. A. E. Ragon, Caroline-street, Bedford-square. Improved machinery or apparatus for stirring or mixing various ingredients or materials to a pasty consistence, the said machinery being especially adapted to the manufacture of bread and other articles of food. (A communication.)

2351. W. Woofe, Gloucester, agriculturist. Improvements in implements for tilling the soil, and in means of drawing ploughs and other implements for tilling through the land.

2352. T. Marshall, 12, Gate-street, Lincoln's-inn-fields, commercial clerk, and W. Marshall, 200, Regent-street, gentleman. Metallic instruments to be used as substitutes for bristles in sewing, stitching, closing, and otherwise joining boots, shoes, and other leather work.

2353. E. Dronke, Liverpool, merchant. An improved mode of manufacturing gunpowder suitable for war, mining, and general purposes. (A communication.)

2354. W. G. Helsby, Liverpool, photographic artist. Improvements in mounting or setting transparent photo graphic pictures.

2355. A. Firth, Bradford, Yorkshire, wheelwright and blacksmith. Improvements in furnaces for heating wheel hoops, applicable also for other similar purposes.

2356. J. Webster, Birmingham, engineer. Improvements in utilizing the waste flux from galvanizing works.

2357. J. Sturgeon, Leeds, consulting engineer. Improvements in machinery for cutting and boring coal and rocks.

2358. W. Oxley, Manchester, mill furnisher. Improvements in pickers for looms.

Dated September 25, 1863.

2363. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved joint for the tubes of surface condensers. (A communication.)

2364. P. Spence, Manchester, manufacturing chemist. Improvements in the production of sulpho-cyanide of ammonium and other sulpho-cyanides.

2365. E. Lloyd, Dee Valley, near Corwon, Merionethshire, engineer. Improvements in rotary engines to be worked by water, steam, air, and other motive power.

2366. M. Schaffhauser, Cernay, Upper Rhine, France, manufacturer. Improvements in the machinery for making paper tubes used in spinning manufactories.

Dated September 26, 1863.

2367. G. Spill, T. J. Briggs, and D. Spill, Hackney Wick. Improvements in the manufacture of driving straps or bands and of flexible tubes or hose.

2368. W. T. Rowlett, 90, Welford-road, Leicester, manufacturer. Improvements in crinolines and hooped skirts.

2369. R. Clarke, Altringham, Cheshire, skirt manufacturer. A new application of material for covering crinolines, and in the manufacture of the said material.

2370. W. Clark, 53, Chancery-lane, engineer. An improved fabric for the production of permanent electricity, applicable for wearing apparel. (A communication.)

2371. J. Spence, engineer, Portsmouth. An improved plastic composition, applicable to the coating of metallic and other surfaces.

2372. A. Gleerup, Copenhagen. An improved construction of gas-burner. (A communication.)

2374. W. Malan, Walpole-street, Deptford, civil engineer, and W. Tice, Downham-road, Islington, gas engineer. Improvements in apparatus for supplying gas to railway carriages and other moving structures, and in apparatus for manufacturing and holding gas in ships and other vessels, parts of such apparatus being also applicable for manufacturing and holding gas elsewhere.

Dated September 28, 1863.

2377. L. J. J. Jean, Paris, gentleman. Improvements in the construction of steam boilers, and in their firegrates.

2378. P. Bourchani, Paris, gentleman. An improved wax-light or candle stand.

2379. P. Cato, Liverpool, ship builder. Improvements in the construction of combined iron and timber ships.

2380. J. T. Harlow, Upper Saltley, near Birmingham, printer, and E. Harlow, Balsall Heath, Worcester, gun maker. Improvements in breech-loading firearms.

2381. W. E. Gedge, 11, Wellington-street, Strand. Improved apparatus for heating by means of illuminating gas. (A communication.)

2382. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the manufacture of boot and shoe toe pieces or tips, and in the machinery or apparatus. (A communication.)

2384. G. Thomas, 50, Chichester-villas, Kilburn-park, builder. Improvements in Louvre shutters and Venetian blinds.

Dated September 29, 1863.

2385. F. Preston, Manchester, engineer. Improvements in machinery for rolling and cutting files and rasps.

2386. F. G. Mulholland, 36, Essex-street, Strand, civil engineer. Improvements in the mode of manufacturing submarine telegraph cables, in apparatus connected therewith, and in the method or principle of laying the same, and in the preparation of the several compounds described for electric insulation and other purposes.

2387. S. Mendel, Manchester, merchant. Improvements in the manufacture of woven fabrics, applicable to covering telegraph wires.

2388. H. Haigh and R. Heaton, Milns Bridge, near Huddersfield, dyers. Improvements in dyeing cotton or other vegetable fibrous substances.

2389. W. Clark, 53, Chancery-lane, engineer. An improvement in the soles of boots and shoes. (A communication.)

2390. W. E. Gedge, 11, Wellington-street, Strand. Improvements in parts of the permanent way of railways. (A communication.)

2391. J. Cooper, Ipswich, agricultural implement maker. Improvements in the construction of harrows.

2392. P. and J. Llewellin and J. W. James, Bristol, brassfounders. Improvements in water closets.

Dated September 30, 1863.

2393. J. J. Chidley, gentleman, 11, Glaskin-street, Hackney. An improved bottle and stopper.

2394. W. Clark, 53, Chancery-lane, engineer. Improvements in musical instruments. (A communication.)

2398. G. Elliot, Betley Hall, Staffordshire, colliery owner. Improvements in props and supports for coal and other mines.

2399. B. Browne, 49, King William-street, London Bridge, civil engineer. An improved sight-piece for rifles. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated September 30, 1863.

2397. E. W. Bullard, Massachusetts, United States. A new and useful machine or carriage for turning and spreading hay, and for other useful agricultural purposes.

Dated October 1, 1863.

2401. J. Mackay, Aigburth, Lancashire. Certain improvements in firearms, ordnance, and projectiles.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, October 13, 1863.

1343. F. Osbourn. Pressing, smoothing, and finishing garments.

1348. E. Ironmonger. Improved loose clip and socket joint.

1354. W. Green. Producing black colouring matters or pigments.

1364. J. Chalmers. Armour for forts and floating batteries.

1370. C. Belcher. Cutting and transplanting turf.

1371. H. C. Coulthard. Packing for the glands of piston rods.

1373. A. Illingworth. Boots and shoes or similar coverings for the feet.

1393. S. Blake, T. Lee, and R. Dutton. Flour and meal mills.

1394. H. Rigby. Steam boilers and furnaces.

1396. H. Pollack. Manufacture of scarlet, brown, and orange colours.

1399. F. A. Calvert. Steam engines, steam boilers, and steam heating apparatus.

1401. A. Q. de Gromard. Musical instruments.

1404. J. Seaman. Cultivation of the soil.

1406. J. H. Johnson. Smoothing irons. (A com.)

1407. W. A. Brown. Railway trains.

1410. C. E. Newcomen. Treatment of peat and other substances containing moisture.

1419. W. E. Gedge. Construction of kites. (A communication.)

1429. B. Dobson and D. Greenhalgh. Preparing fibrous substances.

1443. T. Adams. Slide and other valves.

1449. W. Clark. Obtaining and applying motive power. (A communication.)

1451. M. Henry. Treating floss silk and silk waste. (A communication.)

1455. C. L. Van Tenac. Daily balance book. (A communication.)

1457. W. Walton. Pneumatic hammer.

1460. E. O. Hallett. Constructing the sides of ships, batteries, and fortifications, and applying armour plates thereto.

1465. F. A. and F. Calvert. Burring, ginning, cleaning, and carding fibrous substances.

1476. G. Davidson. Manufacture of paper bags.

1479. T. Wrigley. Filtering or cleansing water or other fluids.

1523. W. Naylor. Compressing, holding, and regulating the pressure of gas.

1539. J. Watts. Manufacture of malt.

1541. W. E. Newton. Manufacture of leaden pipes. (A communication.)

1569. W. Clark. Charging air or gases with combustible vapours. (A communication.)

1601. J. O. Mathieu. Twisting machines.

1672. A. and B. S. Gower. Sowing and harrowing machine.

1692. G. Haseltine. Brick machines. (A com.)

1830. W. Naylor. Safety valves.

1832. P. R. Jackson. Rolling hoops and tyres.

2152. A. V. Newton. Sawing irregular forms of wood. (A communication.)

2162. G. T. Bousfield. Manufacture of illuminating gas. (A communication.)

2205. J. C. Lott. Turning over the leaves of music.

2213. W. H. Tucker. Propelling and steering vessels.

2228. E. Oliver. Lowering and disengaging boats from vessels.

2233. M. A. Muir and J. McIlwham. Winding yarns or thread.

2237. W. Taylor. Manufacture of iron rods.

2314. I. de Angelis. Obtaining motive power. (A com.)

2317. T. E. Vickers. Manufacture of cast steel tyres. (A communication.)

2331. T. B. Daft. Construction of iron ships.

2336. C. Maitland. Mashing apparatus.

2394. W. Clark. Musical instruments. (A com.)

2397. E. W. Bullard. Turning and spreading hay.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed October 9, 1863.

917. D. Mylrea.
920. W. Clark.
921. P. P. Baly.
922. A. F. Maclure.
931. M. Myers.
932. T. Mallinson and P. Williams.
935. G. T. Smith.
940. R. A. Brooman.
941. R. A. Brooman.
943. J. Leach.
945. T. Gray.
946. W. Clark.
949. W. Spence.
950. H. Eaton.
956. I. Baggs and W. Simpson.
959. W. Oldfield.
960. A. Samuelson.
963. R. Knight.
966. J. Goucher.
967. R. C. Clapham.
972. C. W. Siemens and F. Siemens.
976. G. A. Buchholz.
981. C. Blanc.
984. E. W. Hughes.
993. H. Donald.
998. F. E. Bryant.
1000. F. Durand.
1009. R. Richardson.
1027. J. H. Johnson.
1029. L. de Breanski.
1074. S. S. Marling.
1081. H. Worms.
1094. J. H. Johnson.
1095. J. M'F. Gray.
1115. J. H. Johnson.
1156. W. Clark.
1185. J. Shanks.
1242. H. Bennett.
1247. J. Beaumont.
1360. V. Baker.
1445. W. Wells and J. W. Myers.
1778. H. Mège.
2020. P. F. L. B. Him.
2069. J. Fleming.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2429. D. Cope.
2442. E. Gardner.
2445. J. Edge.
2457. G. Bonelli.
2460. J. Ramsbottom.
2462. C. Wheatstone.
2468. R. Hornsby.
2471. T. Whitby and W. Dempsey.
2478. W. Barker.
2499. J. J. Russell and B. L. Brown.
2501. J. Higgins and T. S. Whitworth.
2534. R. G. McCrum.
2348. W. Andrews.
2574. J. and J. Wadsworth.
2792. J. S. Crosland.
2989. H. Jordan.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2352. F. Whitehead.
2358. D. Joy and W. Holt.
2405. T. Allen.

THE MECHANICS' MAGAZINE.

Contents of the Last Number.—

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 23, 1863.

ORDNANCE.

THE expenditure of two millions seven hundred thousand pounds sterling on gunnery experiments, has failed to supply the nation with a gun capable of superseding the now old-fashioned 68-pounder. The forces developed by exploding gunpowder are at once so tremendous, and so anomalous in their effects, that they have hitherto set the skill of the engineer at defiance, the manufacturing arts of the present day proving quite unable to cope with them effectually. The difficulties encountered in the manipulation of large masses of wrought iron at a high heat, are of the gravest character, and generally result in such a deterioration of its structure, that the heaviest guns, forged either solid or in coils, seldom prove good for much. If we resort to cast iron, we find it anything but easy to procure castings of large size, thoroughly homogeneous throughout their structure; and even though such a result could be arrived at with ease and certainty, it is more than doubtful if it would secure the most proper distribution of the strength of the material. These, which may be termed, to some extent, constructive difficulties, are not the most serious we have to encounter. The fact is, that we do not yet thoroughly understand the nature, direction, or amount of the strains to which guns are exposed. We only know certainly, that these are sufficient to tax the metal of which ordnance is made, to an extent vastly greater than that to which like materials are ever exposed in other situations. The most prominent result of this comparative ignorance is, that we are unable to burn quantities of powder proportionate to the size of abnormal cannon, and heavy shot is in consequence inefficient, from its low initial velocity. The success of iron-plated ships, in warfare, depends materially on this fact.

In order to understand what the effects of exploding gunpowder are on a gun, it is necessary to be able to comprehend the division of time into very minute spaces. Fortunately, we have so many practical instances of this subdivision, that illustrations are easily found. Thus, a projectile moving at 2,000 ft. per second, divides that space of time into 2,000 comprehensible parts, and we can conceive of each of these, minute as they are, being yet again divided into 12ths, by the progress of the shot through each separate inch of its flight. Time is merely a relative term; and in many of the operations of nature, a second really represents an enormous measure of duration. The explosion of gunpowder, instantaneous as it may appear to the superficial observer, is not so to the man of science. An explosive compound, known as "white gunpowder," vanishes on the application of a match with a rapidity, compared to which the combustion of gunpowder is extremely tardy; while fulminate of silver explodes with still greater speed. It is pretty well understood that strains are not transmitted through the mass of a gun with anything like the velocity necessary to enable the iron of which it is composed to exert the full powers of resistance due to its sectional area; and, in consequence, the inner surface of the chase is taxed to the uttermost, while the outer rings of the gun experience hardly any strain. It is more than doubtful if any gun of ordinary construction, free from flaws or imperfections, has ever burst on the first discharge, even with proof loads. Yet we know that the duration of guns firing heavy charges is extremely limited. The powers of resistance of the inner portions of the metal are gradually destroyed, and the good qualities of the iron, be it cast or wrought, are broken down and annihilated in detail, from the inner to the outer surfaces. Hence it is that a mere increase in the weight of guns does little good. A repetition of the process of loading and firing is certain to ultimately destroy any gun, provided the force developed by the charges is sufficient to overcome the limits of elasticity of the first fraction of an inch of the metal next the chase. With the largest American ordnance, slow-burning powder can alone be employed in large charges; not because the total bursting strain is less, for the contrary is the fact; but because its action is extended over a longer space of time, and the strain is, in consequence, transmitted in a pulsation or wave, so to speak, through every portion of the metal. Gun-cotton explodes so rapidly, that it breaks down and disintegrates the surfaces with which it is in contact, as though they were formed of glass instead of iron; and its use for artillery purposes has been as yet confined to a few very exceptional cases.

The initial strain, however, of the exploding charge, confined for a fraction of the thousandth part of a second to the surfaces of the chase, and a small thickness of the gun in their immediate neighbourhood, is quickly succeeded by another through the entire substance of the gun, tending to burst it by pressure without impact. Wrought-iron hoops shrunk on a cast-iron gun are of the greatest possible service in this stage of the explosion, by resisting successfully what we may term the secondary strain, which, however, nearly identical as it must be with the first, may not reach the hoops until the shot has been sensibly moved. Artillerists have been aware of these facts for some time, and it certainly appears strange to us that no attempt has ever been made in this country to defend the gun from the first strain of the exploding powder, which is, we believe, the real element of destruction, owing to its localization. Notwithstanding our knowledge of the peculiar and apparently paradoxical effects produced by the combustion of explosive compounds of every kind, scarcely any alteration has ever been made in the methods of loading a gun since the days of "Mons Meg." Cartridges of an invariable pattern are nearly always employed; the powder, placed in a more or less compact mass, fills the chamber or rear end of the chase, in contact alike with the projectile and the walls of the gun. The expediency of a different arrangement, in this country has never been called in question; yet some recent American experiments have given such remarkable results, as would seem to denote that our success in this matter of great guns may yet depend more or less on the arrangement of the charge. We have already alluded to this experiment; still, we deem it advisable to place the details once more before our readers. A 7-in. gun was loaded with a full charge of powder, made up in a cartridge only 6 in. in external diameter, and supported within the bore of the cannon in such a manner, that a clear space of half an inch remained between the circumference of the cartridge and the chase all round; the shot was in immediate contact with the powder. The result of this arrangement was, that while the shot retained its full initial velocity on the discharge of the weapon, the strain on the gun was reduced nearly one-half. The terms of this experiment have been stated to us on authority which we have no reason to consider doubtful. The explanation of the phenomena is not, however, very easy; yet this is not the only one connected with gunpowder which is apparently paradoxical. General Piobert relates an experiment made in 1826 by General Pelletier, in which several pounds of powder were spread on a wooden table laid on soft earth. The combustion of the powder caused only a slight depression of the table; but when the experiment was changed by placing a sheet of paper over the powder, the table was shattered to atoms; and many experiments equally strange in their results will at once present themselves to those who have studied the subject even superficially.

The results obtained by Lynall Thomas, in the course of his investigations, seem to afford conclusive evidence, that the first and by far the most powerful action of fired gunpowder is percussive; the effects produced on resisting surfaces resembling, more or less, those of a blow. The second effect is that of pressure, due to the gases set free by the explosion and expanded by its heat. What the precise cause of this percussive action is, no one, we believe, has as yet pretended to determine. Once the mere fact of its existence is admitted, we are placed in a position to understand in some degree, the *rationale* of the American experiment. The stratum of air between the cartridge and the surface of the chase evidently acted the part of a cushion, absorbing a great portion of the initial strain in its violent compression; the wave of transmitted force being unable to pass through it with sufficient velocity, to affect the gun materially, until the initial effort of the powder had ceased. To the secondary strain the gun was fully exposed, as shown by the pressure plug. The projectile being submitted to the percussive action of the powder and the impulsive force of the gases, of course, pursued its flight as usual. The action is probably much the same in a fowling-piece the muzzle of which becomes stopped with a little snow or earth. Its discharge, under such circumcunstances, generally causes it to burst, especially if the gun is a long one; most probably because the compression of the air extends with such slowness, as compared with the rapidity of the combustion of the powder, that, while one end of the column within the barrel is compressed sufficiently to burst it, the other end is not condensed enough to remove the obstruction. The gun barrel frequently swells under such circumstances, the obstacle being expelled before a bursting pressure is arrived at. Robins found that, by placing the bullet within a musket at the distance of 11 1-5th inches from the charge, its velocity was increased by 200 feet per second; and it has therefore been argued that the passage of a wave of compression through the column of air in the gun, has nothing to say to its explosion when an obstacle is placed in the muzzle. Yet it must be remembered that the recoil of the gun is always materially increased under such circumstances, as well as the entire force developed; while the effect on the projectile must be secondary, and in no way due to the percussive action of the powder—the force, of all others, most injurious to a large gun.

We do not wish to be understood as making any positive assertions on this subject. We prefer suggestion to dogmatism; and we feel certain that the question of the practicability of defending a gun from the initial action of the exploding charge, is one fraught with the deepest interest. A series of experiments carefully conducted with this end in view, are absolutely essential to the increase in our

knowledge of the action of gunpowder, rendered more needful than ever by our continued failures in the attempt to produce a really good as well as great gun. Rapid as the explosion of gunpowder is, there yet remains no room to doubt that the operation is really divided into several stages, each of which is attended with a different effect on both gun and projectile. Did the strength of a gun depend on its power of resisting a steadily exerted pressure, there would be little or no difficulty in making it strong enough to resist a strain of perhaps 30 tons on the the square inch. It is not in the mere pressure of the gases produced by an explosion, that the difficulty resides, but in its, to some extent, mysterious initial force. Whether this force can be absorbed by an air-spring, or otherwise, remains to be proved. It is highly probable that it can. We have no positive evidence to the contrary; and until we have, we will continue to believe in the practicability of the expedient. It may yet be deemed advisable to construct guns with a considerable enlargement at the breech, into which the powder cartridge, probably affixed to the rear end of the shot, would project; a clear space of an inch or so being left all round between it and the metal. Coiled guns have always proved deficient in longitudinal strength. An air-cushion between the powder and the breech, might possibly aid in overcoming this objection. Many of the mightiest forces in nature have been made available for the service of man by careful management. We have encountered the power of gunpowder by sheer brute force for a long time without success; and it is time that we endeavoured to elude that which we cannot conquer.

V. P.

NOMINAL HORSE POWER.

OF all the absurd terms to be met with in the vocabulary of mechanical arts, that of "nominal horse power" is perhaps the most absurd. Particular measures and weights bear, very properly, individual appellations, which, if not invariable in their meaning in a general sense, are so in particular instances. Thus, the term "pound," individually, does not it is true, invariably denote one certain measure of the force of gravitation; different merchants employing it in various senses, according to the kind of trade they carry on. The pound of the jeweller is one thing; that of the corn merchant another. Yet the troy weight of the one can never be confounded with the avoirdupois weight of the other. The phrases "troy weight" and "apothecaries' weight" are understood throughout the length and breadth of the kingdom, and are rarely, if ever, confounded with each other. Measures of length are still more definite. A foot is equally a foot with the carpenter and the engineer, the worker in stone and the worker in iron, all over the kingdom. A two-foot rule which can be used in London is equally serviceable in Manchester and Liverpool, Hull or Glasgow. Our engines are bought and sold at the rate of so much per nominal horse power; and it is certainly strange, considering the enormous sums which annually change hands in the trade, that there should be no fixed and definite meaning attached to the expression. Not only does it convey no idea whatever of the power of any steam engine, but it fails equally in expressing size. Were this all, its use might be pardonable; but, on examination, we find that nearly every centre of manufacturing industry attaches a special value to it, different from that which obtains elsewhere; a nominal horse power meaning one thing at Leeds, another thing at Glasgow, and something else at London; even different makers employing the phrase in distinctive senses, according to their individual proclivities.

It is easy enough to trace the origin of the term. Our coal-pits were, less than a century and a half ago, almost wholly dependent on horse power for their successful working. Yoked to the "gin," four or five horses performed their daily and nightly rounds, clearing the comparatively shallow pits, alike of their produce, and the water which would otherwise have inundated the workings. Hundreds of small mines are worked to this day by similar means, in South Staffordshire and many other mining districts. Savary's engine, introduced about the year 1700, met with but partial favour; and horses retained their place, even after the invention, or rather employment, of Newcomen's engine some fifteen years later. No record exists of the use of the words "horse power" as applied to the steam engine up to or at that time. When James Watt, however, entered on the scene, in 1775, or thereabouts, his engines were found so efficient that they quickly displaced horse labour. Still colliery proprietors and ironmasters, when applying at Soho for engines to drain their pits, were in the habit of measuring the amount of power they required by mentioning the number of horses which the engine was intended to replace. Boulton and Watt, quickly finding this comparative measure of engine power extremely useful, extended it to their advertising sheets, and it thus became all but universal throughout the country. During the first few years of his career as an engine builder, Watt adhered almost exclusively to one particular speed of piston per minute, only departing from it in exceptional cases, when engines were constructed out of the usual routine of the shops. He was not long in business, however, until he discovered that the term "horse power" conveyed too vague an idea to answer the purposes of a vastly extended trade. He accordingly instituted some experiments at one of the London breweries with the largest and strongest horses which he could obtain. A finely-turned brass pulley was affixed to the edge of a well; over this pulley a carefully made rope was run, one end descending the well, where it was attached to weights, altered as occasion required, while the other end was drawn forward by a horse, which thus raised the weight. From the results obtained from this, and some other experiments, Watt determined the power of a strong horse to be equal to a weight of 33,000lbs., raised one foot in one minute; the horse being capable of maintaining this exertion for eight hours per day. This was the highest average obtained from the most powerful horses. Watt's first boilers were worked at an extremely low pressure, not more than 2 lbs. or 3 lbs. on the square inch above the atmosphere His machinery was not very perfect; and the pressure on the pistons of his earlier engines seldom exceeded 10 lbs. or 12 lbs. on the square inch. Newcomen's engines had an available pressure of not more than 7 lbs. or 8 lbs. on the inch. Those who bought from the Soho firm, could scarcely be induced to believe in the possibility of obtaining anything much over this; and as there was a doubt amongst the public, Watt gave them the benefit of it; and determining that his customers should receive even more than they bargained for, he magnanimously adopted the highest possible standard of horse power, and the lowest of steam pressure; and thus the Soho nominal horse power was measured by a piston moving at a speed of 128 ft. per minute, under a pressure of but 7 lbs. to the square inch. Other firms, however, quickly started into existence, who found it expedient to depart both from Watt's standards of speed and pressure, and in consequence different estimates of nominal horse power were adopted in different districts, and continue in force at the present moment. The standards adopted are, in many instances, simply ridiculous. Thus, at Leeds, a nominal horse power means 30 circular inches of piston area, without regard to either speed or pressure; while at Manchester 23 square inches are regarded as the proportion. The weight of a fly-wheel, or the thickness of a cylinder, might be selected as measures of the actual work performed with equal propriety. In Glasgow and London, pressure is employed as the standard; the mercantile value of a steam engine being calculated by an assumed pressure of 7½ lbs. to the square inch at the former place, and 7 lbs. at the latter, the regulation piston speeds being settled by empirical rules which bear little or no relation to practical results. Those adopted by the Admiralty may be selected as an example. The speed is supposed to vary with the stroke. With a 4 ft. stroke the piston speed calculated on is 196 ft.; with 5 ft. stroke, 210 ft.; with a 6 ft. stroke, 228 ft.; with a 7 ft. stroke, 231 ft.; with an 8 ft. stroke, 240 ft. per minute; and so on. It is almost needless to say that these velocities are seldom or never really adhered to. The average pressure maintained in the boilers of our Navy may be taken somewhere about 18 lbs. to the square inch. If to this we add 12 lbs. for vacuum, and deduct 4 lbs. for wire-drawing and loss, the actual working pressure per square inch of piston becomes nearly three times the nominal pressure. It is thus that the indicated power of marine and other engines exceeds the nominal many times. How many depending, in a great degree, on the good faith of the firm contracting for the machinery and not at all on the stipulations of the contract! There are various instances in our Navy and mercantile marine where similar ships attain very different velocities with engines of the same nominal horse power, made by different firms; the speed depending not on the nominal but on the indicated power. Setting the general public aside, we thus find that the Government, by purchasing engines at the rate of so much per nominal horse power, place themselves completely in the hands of the manufacturers. The naval architect may calculate that 2,000 effective horse power is sufficient to drive a particular ship at a certain speed. Engines of 400-horse power nominal are ordered, in the expectation that they will work up to the required power. Whether they do or not rests with the makers. If they develop a force of 1,200 horses only, the designer of the ship is disappointed, but no blame can attach to the makers of the machinery. There are engines at this moment in the Navy giving out eight times their nominal power; many others only three; the first cost of the machinery being as nearly as possible the same in both cases. It is not strange, when we consider these things, that so many of our ships have failed to realize the speeds predicted for them.

A simple remedy exists for this state of affairs. Let the purchaser stipulate how many indicated horse power he requires, and pay for his engines by that standard. Such a course would be found, in the long run, beneficial to all parties. Many firms are at present excluded from Admiralty work because their reputation is not established; and the Government, having no check over them under existing arrangements of purchase and sale, fear to

employ them, lest the indicated should not sufficiently exceed the nominal horse power. The sooner steam engines are bought and sold by real instead of ideal standards, the better. The words "horse power" are seldom or never used in connection with the locomotive; yet purchasers always get exactly what they want. Imaginary and arbitrary measures of either size, capacity, or power, are certain to lead the unwary and inexperienced astray, and are unsuitable to the advancement of the age.

THE PHILOSOPHY OF RIFLING ORDNANCE.

The most perfect system of artillery will be that in which, all other conditions being equal, rotation of an elongated projectile is obtained by spiral rifling with the least tension on the gun.

The simple and obvious mode of imparting rotary motion to a cylindrical shot seems not to have found favour with artillerists. And yet a lesson might be drawn from such familiar examples as a boy's top, a teetotum, or a wheel on its axis. They are set spinning by the application of the motive force, without obstruction or hindrance, to the revolving body. To impart velocity to a carriage, the wheels are allowed to turn freely. To retard its too rapid progress, the break is applied.

Instead of following the simple rule referred to, inventors of rifle systems have recourse, more or less, to the forcing or friction principle. They place the projectile under conditions, which compel it to force its way into or along spiral grooves or ribs, or to burst the gun. One method is the compression system of Armstrong, copied from the Wahrenhoff, which moulds the lead coating of the shot into the grooves of the gun. Another plan is the expansion system, by which a soft metal disc or plug, at the rear of the projectile, is driven by the explosion into and through the rifling of the gun. Of this the Bashley Brittens and Parrots are examples. The friction systems are represented by Lancaster's oval, Whitworth's hexagonal, the French or Commander Scott's iron-winged, and Lynall Thomas's ribbed rifling, the projectiles all rotating by pressure on opposite sides of the bore.

These plans, without exception, are on the forcing principle, absorb by friction a large portion of the propelling power, and in various degrees cause strain on the gun. This strain, retarding the shot in passing along the bore and tending to destroy the gun, is the evil of the rifle systems hitherto employed.

To counteract this evil, singularly enough, all the plans devised have been in the direction, not of avoiding forcing, but of strengthening the gun to enable it to resist the strain—a course which involves increased weight and cost of the piece. But no weight of metal or expense has been sufficient to produce a gun, of large calibre, capable of standing the tremendous tension resulting from forced rifling. Under its ordeal Armstrong, Whitworth, Lynall Thomas, Lancaster, Scott, and other rifled guns have burst when put to a continuous proof test. The experience with American ordnance of a similar character has been the same.

The energy of the explosive force of gunpowder, confined and compressed in a chamber of enormous strength, can hardly be calculated. The blasting of rocks, the explosion of shells, the bursting of great guns, give some idea of its irresistible power. Its effects are those of boiler explosions, when, the safety valve ceasing to act, high-pressure steam bursts its bounds. The action of forced rifling is of a similar nature. The shot which, if it offered no resistance but its weight, would yield to the explosion and be a safety valve for the escape of the elastic fluid, being jammed into the bore, is checked and cannot force its way out of the gun with sufficient velocity. The energy of the compressed gas, not having time for expansion, becomes too intense, the metal yields and bursts asunder, with destructive effects, of which examples are exhibited in the mutilated remains of rifled guns, lying in long rows at Woolwich Arsenal.

So long as the forcing system is maintained, no real progress will be made in rifling cannon. On this subject interesting and valuable data are supplied by the report of the Ordnance Select Committee, ordered to be printed by the House of Commons on the 23rd July last. I extract from it the subjoined table of experiments on different rifle systems, giving the breaking weight in tons for each kind of rifling:—

Table of Experiments on Cast-iron Rifle Sockets.

Extracted from the Report of the Ordnance Select Committee.

No. of Diagram.	Name.	Nature of Rifling.	Breaking weight in tons at circumference
1	Lancaster	Oval	7·02
2	Experimental	Decagon	23·29
3	Sir W. Armstrong	3-grooved shunt	25·65
4	Com. Scott.........	3 grooves in socket, but only 2 ribs bearing...	27·93
5	Whitworth.........	Hexagon	28·07
6	Com. Scott.........	2 grooves opposite to each other	29·0
7	Experimental	2 grooves opposite to each other	29·18
8	L. Thomas	3 ribs	35·09
9	Com. Scott.........	3 grooves..........	35·30
10	Sir W. Armstrong	10-grooved shunt	46·50*

These experiments were carried out by Mr. Anderson, the superintendent of the gun factory at Woolwich. Iron plugs, representing the shot, were forced by torsion into cast-iron sockets, representing the systems of rifling. So far as they go, they afford comparative data; but no positive conclusions can be drawn from them; and great doubt of their accuracy is raised, when it appears that Lancaster's oval bore yields to a breaking weight of 7 tons, whilst the resistance of all the other systems is from 23 to 46 tons, or three to five times greater. From what is known of the oval bore, from the results of continuous firing in competition with other guns, with proof charges, it is apparent that no such discrepancy exists in practice. It is very doubtful, whether mechanical strain, by torsion, is any criterion of the effects of the elastic pressure of exploding gas. The chief merit of these experiments is the evidence they afford of the vast importance of the question, in the opinion of the most practical officer in the ordnance department. It has, no doubt, been seriously considered by the Select Committee; but there is no indication in their report, that they are impressed with the absolute necessity of adopting a mode of rifling which is not on the forcing system.

Mr. Anderson evidently has misgivings in his mind, as to the value of the existing systems. In his evidence he says, "that for some time past, a question has been frequently raised in regard to the tendency, which different descriptions of rifling have to split the gun. The power required to give the rotary motion to the projectile, through the agency of ribs or grooves in the gun, must necessarily cause *an opposite straining in the gun, tending to open it, or else to break the metal without entirely splitting*. We can easily perceive that an inclined surface is more apt to split the structure, than a flat or perpendicular surface; but there were no precise data in regard to the position in which different planes stand with regard to each other."

* At this weight the plug broke, and the cylinder showed a slight crack.

These words convey a plain avowal that all the known plans of rifling tend to *open the gun and split the metal* by the opposite straining of the projectile against the grooves or ribs of the gun.

This is the very evil above pointed out; and to overcome it, instead of employing, as the medium of rifling, a bursting force, which any strength of metal, however great, in the form of a gun, seems powerless to resist, it would be wiser to remove its cause, by producing rotation on the natural principle of causing the projectile to rotate in the bore without obstructing it at all.

As bearing on the question, on the principle of *lucus à non lucendo*, the Ordnance Select Committee have published in their report a table of instructions on the "Mode of Testing the Value of a Gun," in which *they omit any mention of rifling*. Verily, the Ordnance Department does not keep pace with modern improvements in artillery!

Mode of Testing the Value of a Gun for a truly-proportioned Gun.

Extracted from the Report of the Ordnance Select Committee.

	Marks.
Lowest angle of elevation	150
Accuracy at long ranges..	100
Rapidity of loading..	150
Freedom from fouling...	150
Durability and simplicity of arrangement of a breech-loader...	100
Projectile—its cheapness and freedom from liability to injury in service or in store...........................	100
Initial velocity..	150
Destructive power against iron plates at long ranges	100
	1,000

The valuable properties of a gun are here represented by proportionate numbers in one thousand marks; but no place whatever is given to rifling, although it is admitted to be the most important element of the stancture. It may, with reason, be suggested that "simplicity and minimum strain of rifling" should stand at 250 marks at least in the 1,000 marks which are fixed as the standard of a "truly proportioned gun."

If to this condition were added one to the effect that the system of rifling should be of such a nature, as to admit of the weapon being used as a rifle or a smooth-bore, there can be no doubt that a naval and siege gun might be produced of the highest value for both services.

Civilian.

BOILER EXPLOSIONS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Mr. Colburn having, last week, disavowed the chronological inversion of events referred to in my last letter, and acknowledged that our discussion upon the explosion on board the "Great Eastern" took place in the earlier half of the week following the explosion, *before* he published his article on the subject in the *Engineer*, that settles the only point raised in his first letter in your paper of the 2nd instant.

He now prints a note from his friend Mr Holley, in which all that this gentlemen ascribes to him is the suggestion of "the sudden generation of steam upon the reduction of pressure by rupture." But I, too, and hundreds more, have made the same suggestion. In 1854, I conducted a series of experiments on the quantity of steam generated under reduced pressure in steam boilers, the results of which were given in evidence before a Parliamentary Committee in that year. But Mr. Holley says it was suggested as "the groundwork of the percussive theory of

explosions." If this be granted, I have it in evidence from Mr. Colburn that, whilst *he* suggested the sudden generation, *I* suggested the form of action—by percussion; for, he writes to me on the 23rd November, 1859, "*I believe I was the one to suggest the disengagement of the steam from hot water; you confirmed my belief in several ways, and you have given me nearly all I knew of the action of steam by momentum.* My views on decomposition, electricity, &c., are borrowed, and I lay no claim to originality in them." This was written with reference to a wish on his part that I should write an introduction to the proposed joint pamphlet, "stating the share of each."

Again, that he had not, at the time, any conception of percussive action in the explosion on board the "Great Eastern" is clear from his account of it in the *Engineer* of the 16th September, 1859. "The casing," he says, "must have been full of water, which was, *to a great extent* [on the 23rd he suggests *all* the water], instantaneously converted into steam, and with an energy sufficient to complete the catastrophe by exploding the outer casing." That this was not the mode of action, is evident enough when one considers that not more than 1-160th part of the water could have been converted into steam before the explosion, seeing, as he admits, that the first incident of failure was collapse. Not a word about the escape of steam from over the water, nor from the heated water, nor the faintest suggestion or allowance to percussive action at all. But, Sir, this suggestion of the entire conversion of the water into steam, erroneous as it is, was merely borrowed from Harshman, whose views had appeared in his tract of 1855, and parly in the *Engineer*, in the month of August, 1859; and when I refer to Harshman as a precedent for Mr. Colburn, I do not allude to the points of difference between them, to which Mr. Colburn assiduously calls your attention, but to the points of identity.

Moreover, Mr. Holley's version of the explosion, in his account of the trip, in the same number of the *Engineer*, of the 16th September, 1859, is like that of Mr. Colburn, with a difference. He says:—"*All* the water in the heater, some tons, being at the heat of steam at, say, 50 lbs., when the pressure of 50 lbs. was removed, would flash off into steam *of a lower pressure*, but of immense volume, which in its effect is equivalent to a *terrifically high pressure*." If *all* the water had flashed into steam, the pressure would, no doubt, have been terrifically high; but only 1-160th part of it could have flashed into steam. There is novelty in the equation—

Low pressure + immense volume = terrifically high pressure.

In a postscript, Mr. Colburn refers to a volume of the *American Engineer* for 1857, to show that he dwelt strongly upon the distinction between rupture and violent explosions. Harshman did so before him, in his tract of 1855, and Mr. Colburn says he has read that book. I have today asked him to give me a sight of it, but he won't let me see it.

Respecting the historical summary of our communications, in Mr. Colburn's last letter, it abounds in chronological inversions and misstatements. I deny that I used an oath; I deny that I acknowledged appropriations from the *Engineer* in the *Encyclopædia Britannica*. But it is not my purpose, on this occasion, to attempt to exhaust the discussion; besides, I see Mr. Colburn leads off on a new tack—that would occupy a great deal too much of your space. But I again propose, as I have done before, to refer the whole matter under discussion to the decision of competent persons, and to abide by their decision. Meantime, as a fair summary, so far as it goes, and as a fair equivalent for Mr. Colburn's recapitulation, I subjoin a literal copy of a recapitulatory communication I made to Mr. Colburn, dated February 13, 1860:—

"*Summary of Events and Confabulations.*

"1. Jacob Harshman, U.S. (see the *Engineer*, August and September, 1859), said that when a boiler exploded, all the water exploded and disappeared, and a big cloud (in one case 15 ft. in diameter) arose in its stead. He recognized, as a common supposition, and discussed percussive action within the boiler. Said that explosion of mere gas or steam only was comparatively trifling. But steam with water, terrific.

"2. Z. C. and D. K. C. talked about this for two or three hours. Adjourned.

"3. Z. C. afterwards insisted that, in an exploding boiler, all the water flashed into steam of enormous volume (see Harshman). Also, that explosion of mere air or gas is trifling compared to explosion of steam and water (see Harshman again).

"4. D. K. C. wearied of this—(variations of Harshman)—scientifically absurd. Said that water could not all be evaporated, and inherent pressure could not be greater after than before explosion.

"5. Z. C. strangled all theories based on electric action, hydrogen, oxygen; and exploded them, as I thought, at once and for ever.

"6. Z. C. hammered at it, made no progress, wondered, and said there must be something yet, not understood.

"7. D. K. C. roused, said, though inherent pressure could not increase, yet the violent separation of steam and water would dash the contents like small shot against the surfaces of the boiler; and, in this way, by percussion, vastly increase the destructive action.

"8. Z. C. did not immediately adopt this, but did so soon. Asked D. K. C. if he really believed there was weight in the steam for the job. D. K. C. gave him various illustrations. Vastly pleased (that is, Z. C.). Z. C.'s faculties as compiler and lecturer set to work. Supposed to have written the lucid leaders about explosions that subsequently appeared in the *Engineer*.

"9. Explosion of the 'Great Eastern.'—D. K. C. gave Z. C. and A. L. H. his views on it, and the circumstances:—as want of stays, similarity of chimney to a large flue, head-pressure of water in stand-pipe greatly increasing the pressure at the lower end of the casing; similarity of collapsed chimney to a piston or plunger, and consequent rocket action; all of which were duly embodied in articles in the *Engineer* of the next Friday—to which my friends were perfectly welcome. D. K. C. explained also why inner and outer cylinder of casing burst at the same time—by collapse first, then reaction of water and steam rebounding on outer casing. Even then Z. C. was not at home with my [to him] new views. Confesses he did not understand them. Leaders on the 'Great Eastern' here and there misty. For example, why, if Z. C. knew all about rebounding of steam and impact at that time, did he call 400 lbs. per inch an incredible pressure? (*Engineer*, September 16, 1859, page 209.) He will try to explain this by saying he meant inherent still pressure. But, if so, why did he not in triumph bring forward the percussion theory? Because he did not appreciate it then. Galloway was right after all.

"10. In second leader on the 'Great Eastern,' *all* the water is supposed to be converted into steam after explosion. Z. C. says he wrote these leaders.

"11. Z. C., being, like many other excellent and capable engineers, in doubt and ignorance of properties of steam generally, was, about this time, frequently applying anxiously to D. K. C. for a proof of his article on *Steam*, written for the *Encyclopædia Britannica*.

"12. Frequent confabulations between Z. C. and D. K. C.

"13. Z. C. proposed a joint pamphlet. D. K. C. assented.

"14. Z. C. proposed to do it himself. D. K. C. resented being made a tool of. Z. C., having got primed by D. K. C. about the ('our') theory, and acquired a few clear views, thought he could go alone.

"15. But Z. C. cannot go alone. If leaders in the *Engineer* represent his views, he does not yet understand the theory. He seems a good compiler, assimilator, and (though violent) critic of other people's ideas, but cannot originate.

"16. D. K. C. conceived percussive action, or rather applied it to exploding boilers, not knowing at that time, nor till lately, what Harshman had been saying. D. K. C. afterwards glanced all through Harshman's paper (in the *Engineer*), and found Z. C.'s first proposed, but now cast off, ideas developed there, as well as the distinction between explosions of mere steam or gas, and those of steam and water together. Another idea put forward by Z. C. (see clause 3 *ante*). Did Z. C. borrow those notions from Harshman or not?

"17. Z. C. now repudiates those ideas—as to total disappearances and conversion of water into steam. Says he never entertained them (see clause 10 *ante*). D. K. C. does not pretend to know what Z. C. thought. He only knows what Z. C. said, and has read leaders in the *Engineer* on the subject, which Z. C. says he wrote.

"18. In the Mechanics' Magazine of the 10th inst., D. K. C. touched on one of the essential elements in violent boiler explosions, unappreciated by Z. C."

I am, Sir, your obedient servant,

D. K. Clark.

10, Adam-street, Adelphi,
October 21.

P.S.—I see Heenan has been sparring again with his back to the sun, without tossing for the corner, in the *Engineer* of last week. Mr. Colburn has another leader on boiler explosions, which I suppose I must accept as a rider to his letter last week, though he is careful to ignore the Mechanics' Magazine. But, as I have said above, he is off on another tack. He now attempts to prove that my account of the explosion on board the "Great Eastern" is all wrong; and he affirms that when the chimney collapsed, there could not be a sudden reduction of pressure by the sudden enlargement of volume (!!) except there was a rupture. This is a new—the third—explanation he has propounded. First, it was collapse alone; second, rupture alone; and now it is a combination of them both. Again, he questions the fact of the rebounding of the steam and water from the collapsed chimney, "as there is nothing to suggest it," says he—except, I may add, that the elastic mixture of steam and water closing upon the collapsed flue, would be suddenly arrested, which, in my opinion, forcibly suggests a reaction or rebounding. I have no present concern in following Mr. Colburn through his lucubration; it is exclusively devoted to an attempt to break down my theory of the violence of that explosion, probably with the object of weakening my claim to the origination of my projectile theory.

D. K. C.

NOTES FROM THE NORTHERN COLLIERIES.

COLLIERY ENGINE BEAMS.

A recent visit to Durham and Northumberland, in common with so many representing the science and manufacturing arts of Great Britain, whose steps were directed to Newcastle by the just concluded meeting of the British Association, enables us to place before our readers a few notices of the latest improvements made or projected in the coal trade—the grand staple of the north, and the material basis of all the rest of its mighty industries. Without coal, in the rich abundance, and of the fine quality in which it is won from the northern beds, the industries of the north could never have taken their existing *form* or reached their amazing development; but *with* the coal, a less intelligent, energetic, and persevering race might have slumbered on for ages of slow improvement, and left still the better part of "their talent buried in the earth." The Northumberland and Durham of to-day, is the joint result of great natural gifts, and of the good use made of these by one of the most magnificent races of men, intellectually and physically, that England, rich as she is in heroes, can anywhere boast of.

No peaceful calling, not even that of the mariner, is more heroic in its character than that of the collier—none that we can call to mind demands a larger amount of intellectual vigour, combined with physical prowess, or a more incessant need for vigilance, contrivance, and resource, nor any that affords field for the application of a larger amount of sound and true knowledge of physical science.

In this last respect our own observation leads us to regard the men of the North, who supply the brain that leads the masses of northern labour to the victories of industry, as sensibly in advance of the corresponding leaders in other parts of our country. It nevertheless seems to us that the educational apparatus by which applied science is disseminated amongst the new generation of the skilled leaders of industry, in the North, as well as everywhere else in Great Britain, is lamentably defective, and beneath the standard that is required to enable us to hold the place we have won amongst the workers of the world. To that subject, industrial education in Great Britain, we shall hereafter return, as to one full of the gravest interest and import to the people, polity, and position of England.

At present we but propose to ourselves some remarks upon a few separate subjects belonging to coal-mining. We shall treat them under consecutive heads, though without any attempt at scientific order or system. No text, even to the merely popular reader, is to be found more interesting, perhaps, than "the economy of a coal-field," nor one that more tempts a writer into diffuseness in his admiration of the innumerable expedients and contrivances, mostly upon the vastest scale, by which the coal, in spite of every natural obstacle and difficulty, is hewn from its bed, five or six times the height of St. Paul's in depth below the surface, and made to fly up into the light of day, and thence transferred from point to point with the minimum of labour, loss, or breakage, until it is finally burnt as the fuel of our own hearth, or in furnaces or manufacturing processes in all corners of the earth; in illuminating our assemblies and cities, in dissipating the freezing chill of Russian or Canadian winters, or bringing the steamship to its required haven, and the railway train to its destination.

We address ourselves, however, chiefly to those to whom such considerations, though they can never lose their poetry, are familiar, and to whom "the practical" is that which is at once the most useful and acceptable.

We shall begin, therefore, with some remarks on pumping-engine beams for collieries.

The dreadful accident of the breakage of the pumping-engine beam of Hartley Colliery on the 16th January, 1862, produced a decided and general *feeling* in favour of such beams being made of malleable iron only, instead of cast iron. In this feeling, we believe all experienced makers of pumping-engines and coal-mining engines are by no means unanimous. As a matter of *feeling*, and looked at with the lights usually brought to bear in writing a leader in the *Times*, the choice seems obvious and beyond question in favour of wrought iron; but we are not aware that the question has ever yet been considered in a way much more distinct and exact than this:—"Wrought iron is tougher than cast—the tougher thing will not break as easily as the brittle one—therefore, let us abandon cast iron for engine beams and adopt wrought." And the adoption has been carried out in some instances.

At Newcastle, at the exhibition of objects of scientific or other interest or novelty, produced at the Central Exchange, during the British Association's meeting—an exhibition whose character we may say in passing was highly creditable to Northumberland in every way—a model was shown by Messrs. Joicey and Co. (374), of a malleable iron beam for colliery pumping engines. It was a well-devised box girder beam, consisting of two vertical sides bounded by elliptical curves at top and bottom, and connected by a flat web plate all round, divided by diaphragms at various points, and provided with the requisite bosses, &c., for the several gudgeons or axes of the beam and of the parts of the engine. The joints, &c., being all double lapped and double rivetted. No doubt, as good a structure probably as could be put together of boiler plate, so far as could be judged from a model only to a small scale; but we submit that this does not decide the question whether wrought iron, in any form, be upon the whole preferable to cast iron, *applied in the best manner*, for such engine beams; and if so, whether boiler-plate work in any form be the best possible mode of applying wrought iron, whether it may not have itself, however convenient and cheap in formation, some special disadvantages; whether some far better form of wrought-iron work might not be conceivable; and finally, whether some material such as steel might not be superior to both cast and wrought iron.

We may not be able to enter upon all these points, and indeed might not be able to settle them; but preliminary to all other questions of the sort, it has always appeared to us that it ought to have been settled in the most scientific, positive, and *demonstrative* manner, how, and in precisely what way the Hartley beam (that originated by its fracture this proposed change of material) gave way—that is to say, that it was all-important to have discovered at the time of that accident, by the clearest chain of circumstantial evidence available, *how the fracture occurred*, and to have sealed the truth of the conclusion come to, as to the immediate cause, by *demonstrating, upon rigid principles, that the motions and forces so concluded upon, were sufficient to have produced the effect attributed to them.*

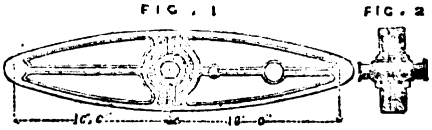
This, it appears to us, has never yet been done. The evidence given at the coroner's inquest had the usual amount of looseness and inconclusiveness, and at any rate, throughout it (as reported) no attempt to demonstrate, upon mechanical principles, the precise train of forces that caused the fracture, is to be found.

The official report made to Sir George Grey, Secretary of State for the Home Department, by Mr. J. Kenyon Blackwell, one of the Government Inspectors of Mines—a clear and able document upon the whole—*suggests*, rather than affirms, the train of causation that resulted in the fracture; but the author does not commit himself even to a clearly dogmatic affirmation of the cause, and makes no attempt whatever to demonstrate, on mechanical principles, whether what he suggests as having led to the catastrophe, was *adequate* to produce the results he is to be understood as having attributed to it.

This report of Mr. Blackwell's is, however, the most precise and authentic document, we presume, before the world on the subject of the Hartley beam breakage; and in view of a case so grave as this, one in which 204 persons perished as a consequence, it certainly does not reflect much credit upon British science, that an event so full of peril and agony of heart to many, and from which such lessons as should effectually avert a recurrence ought to have been educed, has been suffered to pass by unimproved, beyond what may be extracted from the merely suggested and undemonstrated conclusion of the report we have referred to.

Let us very briefly refer to the facts. The engine beam that broke was a double-flitched beam of cast iron of the form shown in figs. 1 and 2. It

FIG. 1 FIG. 2



was 34.5 ft. long from centre to centre of the end gudgeons; it was 8 ft. deep at the centre (according to Mr. Blackwell's report), 8 ft. 2 in. as stated by Mr. Short at the inquest, and 8 ft. 7 in. as given and figured in a contemporary and usually well-informed journal. In this singular discrepancy upon so important a point, we must accept the first as the only authentic statement. Each flitch was 4·75 in. in thickness, exclusive of the metal of the ribs and boss. They were pierced with an hexagonal eye, for the centre gudgeon, the diameter from side to side of the hexagon being 1·75 ft., and this centre of motion was 8 in. nearer to the end of the beam over the pit, than to the other at which the steam cylinder was placed.

The centre gudgeon was keyed in by large rectangular keys, driven (in pairs on each flat of the hexagon) by the sledge or tup, and with great force. The engine was a double-acting one, *i.e.*, it condensed at both sides of the piston; its stroke was 10 ft., cylinder 86·5 in. diameter, steam in boiler 14 lbs. pressure. It had at a previous period worked at 4½ strokes per minute, but at the time of the accident was working 7½ strokes per minute. We must presume it to have been regulated by a cataract, as we cannot suppose continuous work at the velocity of 90 ft. a minute, or even of 150 ft.; and, if so regulated, the velocity of making the stroke will have been nearly the same in either case, and then, the following passage in Mr. Blackwell's report is difficult to comprehend: "That liability to breakage existed in this engine was proved by a former accident which occurred in 1858, when its *speed* was only 4½ strokes per minute, instead of 7½ strokes, as at the period of this accident" (p. 31).

The engine worked three sets of pumps—two, one lower and one upper, in the pit shaft, both bucket pumps, of 2 ft. diameter working barrel, by 9 ft. 3 in. stroke. The dry spears were of Memel timber, from 14 in. to 10 in. square. The bottom set lifted the water 52 yards, to the other, which raised it 66 yards to the high main seam.

The third set of pumps were situated at the engine cylinder end in "a staple." They were bucket pumps also, 2 ft. 6 in. working barrel, 6 ft. 3 in. stroke, worked from the engine beam between the cylinder and beam centres. There was a counter beam and balance weight shackled on to the engine cross-head above the cylinder, to balance the whole system, as shown in the lithographs published at the time by Lambert, of Newcastle. This is also distinctly stated by Mr. Short, the engineer of the colliery, at the inquest—"the load of the engine is balanced by a counter beam." (*Times*, Feb. 6, 1862). But Mr. Blackwell does not mention this, and says the balance was produced by "the smaller weight of the top set in the staple, which was connected with the engine beam on the opposite side of its centre of motion to the bottom and middle sets, was compensated by the difference in length of the two ends of the engine beam from the centre of motion—the weight of the steam piston, the piston rod, cross-head, and iron catch-pin attached to the beam" (p. 30).

The pressure on the steam piston, by steam and vacuum, Mr. Blackwell says, was about 62 tons. The weight of the wet and dry spears, buckets, and columns of water in the two sets of pumps in the pit shaft (at the outer end of the beam) when the engine was about to make a stroke indoors, he states, was about 55 tons. Mr. Short, the engineer of the colliery, stated at the inquest that the weight of the engine beam itself was 42 tons, and "the total weight on the beam working both in and out," between 107 and 108 tons. He also stated, "the weight it had to lift, including the spears and the column of water, was 43 tons 18 cwt., and that the united weight of the engine piston, and rod, and cross-head, was 11,536 lbs. —rather more than 5 tons" (*Times*, Feb. 6, 1862.)

There is a good deal of discrepancy here between parties, both of whom must be deemed authorities. It would appear, however, that the active load upon the beam was something between 108 and 117 tons, and that its passive load was its own weight and those of its attached appendages in addition.

The beam had been cast at the Walker Iron-works, and Mr. Warence deposed that it was composed of ⅔ Blaenavon No. 3 cold blast iron, mixed with ⅓ No. 1 O.M.O. Scotch pig. It was also proved, we believe, to have been flasked, and not cast in open sand, as stated by Mr. Hoskings, C.E., at the inquest. The cast iron was examined at the School of Mines, Jermyn-street, and we are indebted to Dr. Percy for the following determination made of the amount of injurious constituents present in 100 parts of iron, and carbon, &c

Phosphorus	... ...	1·11
Silicon	... ...	2·68
Sulphur	... ...	0·16

The iron, therefore, was by no means bad in quality. The beam suddenly broke right through the eye, the fracture running in the direction marked in the fig. by a dotted line, and passing through the two diagonally opposite, sharp re-entering angles of the hexagonal eye—in this, as in every other case, showing that the fracture chooses not the very weakest *measured section*, which here would have been right across the beam, but the weakest place, section and quality of material taken together. Here through these angles, where "planes of weakness" were induced by the peculiar crystalline arrangement induced by the sharp angles of the eye.

The fracture showed no old crack, it was bright all over; adherent shreds of torn out iron, were remarked upon by one witness as a proof of the toughness of the metal; but no observation appears to have been made by any one with a view to determine which was the compressed and which the extended side of the beam at the time of fracture; whether by the position of these shreds above or below the axis, or otherwise; a most singular omission, when we bear in mind that the point most important to be determined in the first instance was, whether the beam broke by a force acting from below upwards at one end, or by one acting in the reverse direction, *i.e.*, whether by a concussion after the pump spears broke, or by a dead pull suddenly arrested. The fracture also showed four great "draws" or hollows left by the shrinkage of the metal as it consolidated. These were at the sides of the central bosses, where the solidifying iron remained last liquid in the mould.

The pump spears in the pit shaft were both found broken. Mr. Coulson, the veteran master sinker of eighty-four coal-pits, and whose voluntary and unremunerated exertions to relieve the buried men, along with those of his son and foreman, have made their names justly renowned, deposed that the fracture was about 14 fathoms from bank, in the main spears, and opposite the middle seam, *i.e.*, about 60 yards lower in the other spears; both he and Mr. Short appear to intimate that the fracture of the timber indicated *a pull asunder end on*, and not a cross fracture.

There appears some discrepancy also as to the quality of the timber, some of the witnesses at the inquest stating that at the fracture it was perfectly sound, an opinion that from personal communication we are aware is Mr. Coulson's also. Mr. Blackwell, however, states "the wood in the bottom dry spear near the place where it parted was found to be not perfectly sound" (p. 30).

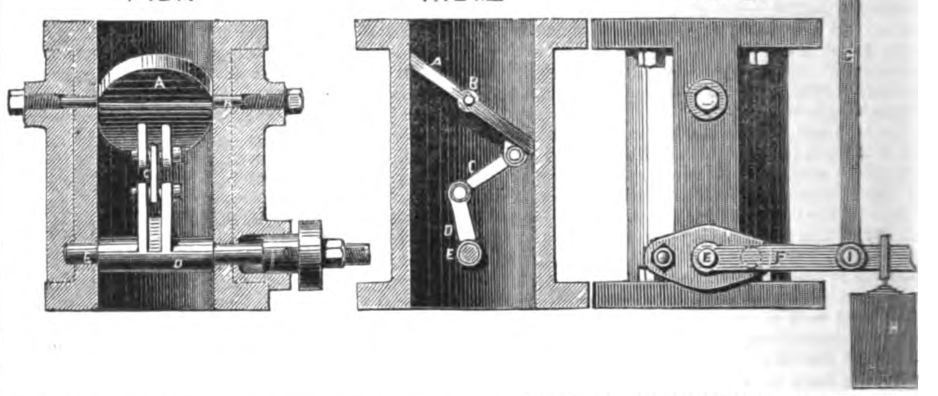
The engine piston, &c., had completed a down stroke after the beam had broken, the cylinder end of the beam had come down heavily upon the catches and spring beams, and the cross-head or piston cap had been fractured. The pumps in "the staple" had nothing wrong with them.

The outer end of the engine beam, on breaking off, plunged down the pit shaft, carrying the wooden brattice (which ran east and west, while the length way of the beam was north and south) crashing down into the shaft before it, and blocking up the latter with debris from the shaft lining, and the ruin of the pit work generally, at about 138 yards from the bank, where all were arrested by the oak buntons on which the middle set of pumps rested. With these details, or with the terrible circumstances of the imprisonment of the men and the heroic efforts made to release them, continued for long after they had been released from all bodily suffering by the easy death of suffocation by "the stythe," we have nothing here to do.

What we propose to consider, by the help of mechanics, how far confidence may be placed in either of the solutions that have been given of the precise train of forces that produced the accident, and then to draw some practical conclusions, amongst others, as to the comparative advantages and disadvantages of wrought iron or other beams, as substitutes for cast iron. For the mathematical treatment of the question, we are indebted to our distinguished friend and contributor Professor Samuel Haughton, Professor of Geology, and Fellow of Trinity College, Dublin. We must, however, reserve the continuation of the subject for following parts of the *Journal*.—*The Practical Mechanic's Journal.*

DUGDALE'S THROTTLE VALVES.

FIC.1 FIC.2 FIC.3.



DUGDALE'S IMPROVEMENTS IN THROTTLE VALVES.

The object of this invention, patented by Mr. A. Dugdale, of Paris, engineer, relates to an improved method of mounting and actuating throttle valves. As now practised the throttle valve is worked direct from the governor, a rod from which is connected to a lever or arm on its spindle.

This arrangement is open to objection, inasmuch as it causes the spindle to wear loose in its bearings in consequence of the continual friction to which it is subjected.

In order to remedy this serious evil the patentee arranges the valve in such manner that the pin upon which it is mounted or turns shall be entirely independent of the actuating parts, and shall serve merely as a pivot for the valve to turn upon, the parts for transmitting the movement of the regulator being connected to one extremity of the body of the valve, and not, as in the plan now in use, connected to the valve shaft.

This arrangement is represented at Figs. 1, 2, and 3 of the accompanying drawing; figs. 1 and 2 being longitudinal sections taken through the middle of the steam pipe, provided with its throttle or regulating valve, which in these two figures is shown in the position in which it would be in order to completely close the steam pipe; fig. 3 is an elevation or exterior view of the steam pipe, showing the parts for actuating the valve. In these three figures corresponding parts are indicated by similar letters of reference.

In the improved arrangement of throttle valve the body A of the valve turns upon a pin B passing through its centre; the valve A is actuated by means of a link C connected to a forked arm D mounted upon the shaft E. Upon this shaft, but outside the pipe, is a lever F hinged at I to the actuating rod G. The lever F is provided with a moveable weight H for the purpose of acting upon the valve. The figures show the manner in which the different parts are mounted in the steam pipe, and it will be seen that in this arrangement the pin B being placed in the middle of the thickness, and in the line of the smallest diameter of the body A of the valve, this pin must necessarily in all positions be subjected to about the same pressure, and allow the plate to turn freely as upon a hinge or two pivots.

Toothed sectors, or other equivalent mechanical arrangements, may be employed instead of the connecting-rod or link C and arm D for transmitting the movement of the shaft E to the valve.

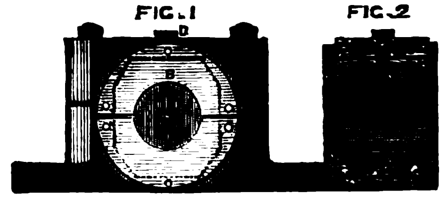
BURTON'S IMPROVEMENTS IN SHAFT BEARINGS.

Mr. J. W. Burton, of Leeds, has recently patented an invention which has for its object the combination of the materials hereinafter stated, so as, when combined, to form a substitute for the materials hitherto employed for the purpose.

The bearing, or part on or against which the axle or shaft-works, is composed of glass or other similar hard and smooth material or composition, and the flanges or ends or outer parts are composed of brass or other suitable metal or alloy, and there is inserted between the bearing and the flanges or ends pieces of wood, papier maché, felt, india rubber, cloth, or other similar non-metallic and partially elastic substance or material. The several parts are united as required by means of countersunk bolts, or in any other convenient manner. By this combination of materials there is provided a hard and smooth bearing of a more permanent character than those in ordinary use, resting at each end against a kind of cushion of partially elastic material.

Fig. 1 in the accompanying drawing is a side

FIC.1 FIC.2



elevation of a plummer block or bearing for a shaft or axle; and fig. 2 is a transverse section of the same. A is the bearing or part on or against which the shaft or axle works, and is composed of glass or other similar hard and smooth material or composition; B, B, are the flanges or ends, composed of brass or other suitable metal or alloy, which form the outer part or casing of the bearing A. Between the parts A and B are inserted pieces of wood, papier maché, felt, india rubber, cloth, or other similar non-metallic and partially elastic substance or material C, shown by dotted lines in fig. 1. The parts are shown as connected together by means of countersunk bolts. D is an ordinary oil cup. It will thus be seen that by means of the above-described combination a shaft or axle inserted in the plummer block in the usual manner would be provided with a hard and smooth bearing of a permanent character at A, resting against a kind of cushion of partially elastic material C, enclosed by the metal flanges or casing B.

PERFORMANCE OF AMERICAN IRON-CLADS.

The following interesting communication from an engineer in the United States Navy has appeared recently in a New York paper. This gentleman, writing from his ship, off Charleston, says:—

Those who are interested in the success of our iron-clad navy will be pleased to hear of the invulnerability of the pioneer of our ocean iron-clads the "New Ironsides." Of the 213 shot and sh-

that have struck her during the attacks on Charleston, none have caused any serious injury to life or limb, nor any apprehension for the safety of the vessel. The most probable source of danger is from a shot or shell entering the ports. Each port is protected by two port shutters, which are wrought-iron plates that shield the port, on the same principle that the plate covers and uncovers the keyhole of a lock, except that the hinges are on the inside upper corners, instead of the centre of the top of the plate, as in the lock. Although these port-shutters are 5 in. thick, they cannot resist the impact of a shot which strikes them while they cover the ports; and, in proportion to their bending, is the difficulty of working them.

The hinges have so little metal around them, that, if a shot strikes them, the shutters almost invariably drop off. Both of these defects, however, can be easily remedied. The rebels have paid particular attention to the water-line and machinery of the ship. The water-line bears the imprints of ten 10 in. solid shot. The most serious damage resulted from two shots striking the same plate, within a foot of each other, and within a foot of the end of the plate. The result was, the partial cracking of the plate, bending it, and forcing it about an inch into the woodwork. It occasioned no leak in the vessel.

The method of fastening the plating to the sides of the ship is very effective. It consists of common wood-screws, put through the plates from the outside, and tapped into the wood, having cylindrical heads countersunk into the plating and flush with the outside. Several of these screw-bolts have been struck directly on the head without causing any damage, whereas, if the ordinary plan of using through bolts or rivets had been adopted, it is very probable that some persons would have been injured by fragments of the bolts being projected inside the ship. Captain Badger was seriously wounded while in the turret of the "Patapsco," by being struck by one of the bolts that held together the several plates that compose the turret. Several 10 in. solid shot, and one 11 in., have passed through the unprotected part of the bow and stern; but so much of their momentum was lost in the passage, that they did not reach the wrought-iron bulkheads that cross the ship forward and aft, and which would have effectually stopped their further progress. The 11 in. shot came from one of the guns of the ill-fated "Keokuk." It was originally a poor casting, and the rebels apparently had to turn one-half of it in a lathe before it would fit the gun.

The appearance of the smoke-stack indicates good shooting on the part of the rebels. A dozen shots and fragments have passed completely through it, all of them within 15 ft. of the deck. One shot would, undoubtedly, have passed into the boiler, but that it was deflected by the wrought-iron grating in the smoke-stack, placed there for that purpose. The projecting woodwork on the spar-deck is torn into shreds, and one-third of the rail is completely carried away.

It is claimed for the "Ironsides" that she is equivalent to any six of the "Monitors." It is certainly the case that when she brings her broadside to bear, and opens fire on the rebel batteries at a thousand or twelve hundred yards range, the rebels very soon leave their guns and take to their bomb-proofs. They have so much respect for her shelling propensities that, although often at anchor within their range, taking in ordnance or coal, they do not disturb her. An idea of her capacity for distribution may be formed from the fact, that in the attacks since the 7th of April, she has fired 4,439 shells, 3,333 having been fired at Fort Wagner.

Of the machinery it may be said that it combines, with neatness of design and excellency of workmanship, that most essential requisite in the machinery of an iron-clad—simplicity. It consists of two horizontal direct-acting engines, with one surface condenser in common, and a double-acting air and injection pump to each engine. A double-ported balanced steam slide valve to each engine, cutting off by the lap at two-thirds of the stroke of the piston, and each worked by a link motion, constitutes the principal porti n of the machinery. Four horizontal tubular boilers furnish all the steam required. The engine-room is the finest of any screw-ship in the service, while the fire-room is about the most uncomfortable of any vessel of her class. During a late attack, with the fires spread, and the furnace doors open, the temperature was 170 deg. This is, of course, the extreme; the ordinary temperature, however, being 120 deg. Two blowers with their separate engines, are arranged to supply air to the fires, or to force air on the gun-deck during action. The latter is the only purpose for which they are used. The greatest defect in the ship, not connected with its invulnerability, is the want of ventilation on the berth-deck. The ward-room has the benefit of a windsail and air-ports; but the steerage, in which 17 officers have to live, has no ventilation whatever. Each room is nothing better than a box. Officers enter their mess-rooms, eat their meals, and then rush on deck to get fresh air. There is not even a windsail, although there are two hatches, communicating with the spar-deck, in which they could be placed. An expenditure of a little time, and less money, applied to the construction of air-tubes leading to the blowers, with branches leading into each room, would result in the officers' enjoying health and comfort.

An Engineer in the U.S.N.

ENGINES OF THE "PURITAN" AND "DICTATOR."

These two magnificent vessels of war, now fast approaching completion, will certainly be unsurpassed in their speed and invulnerability. We do not suppose that twenty miles per hour will be got out of them, as is stated; but we do think that three-fourths of it is not too much to expect when their models and engines are considered. We have had an eye on the construction of the machinery for some time, and have taken great interest in it. The following details will be found of general interest:—The cylinders are 100 in. in diameter, and the piston has 4 ft. stroke; they are "kettle-bottomed," being cast solid, of the same shape as that utensil named; they are 2½ in. thick through the sides, and have 4 strong lugs by which they are held to their places. They stand vertically, and have no bed plates; in fact there are none for the whole engine, but the cylinders are bolted to two massive wrought-iron kelsons, 10 ft. deep and some 24 in. or more in width; four huge bolts secure each cylinder to the kelsons. The cylinders are both in line, athwartships, and have large slide and expansion valves, the latter working over the former; in each valve there are two stems which proceed to strong cross-heads working between vertical guides on the end of the steam chests. The chests are bolted, not cast, to the cylinders.

A peculiar feature of this machinery is the absence of guides, cross-heads, and other cumbrous parts. The piston has a trunk attached to it, but the engines are not, strictly speaking, trunk engines. The usual connection is attached to the bottom of the piston, runs up the trunk, and takes the end of a lever attached to a vibrating shaft running fore and aft; this shaft transmits the power of the piston to the propeller or screw shaft; it is supported in wrought-iron blocks, with brasses, as usual, and has a vertical lever placed on it, from which the main connecting rod proceeds directly to the crank pin; these are the principal parts. The vibrating shaft blocks are bolted to the kelsons (of which there are six in all), and there is one shaft to each cylinder, making two shafts, two connecting rods, and two trunks between the pistons and the crank pin. The air-pump is placed inside the condenser, and worked by a lever on the end of the vibrating shaft. The condenser is of the old-fashioned jet variety, and sits directly aft the cylinders. The shaft is 21 in. in diameter, is 72 ft. long in several sections, and works in a tunnel or alleyway made for it.

The boilers have 56 furnaces, and an aggregate grate surface of 1,100 ft.; allowing 12 lbs. of coal per square foot of grate surface, the vessel will require at the least 175 tons of coal per day, of 24 hours steaming, at full speed.

These engines are precisely similar in all respects for each vessel; the propeller is 21 ft. 6 in. in diameter, has 32 ft. pitch, and weighs 39,000 lbs.; there is no out-board bearing for the shaft. What piston speed will be obtained from the engines remains to be seen; we hope that the highest expectations of the builders, and the designer, Captain John Ericsson, will be attained.—*Scientific American.*

TRIAL OF ARMOUR PLATES, STEEL GUNS, &c., AT ST. PETERSBURGH.

On Wednesday, the 17th of October, N.S., further trials took place at St. Petersburgh with the experimental 9-inch rifled cast-steel gun. The *Times* states that this gun is of solid cast steel, made by Krupp, and throws a 300 lb. shell or a 450 lb. solid shot. The results of previous experiments with this gun led the Russian Government to order 50 of them, which are now in course of delivery. The principal objects of the experiments on the 7th inst. were to ascertain the best description of shell, and to test the quality of armour plates supplied by Messrs. John Brown and Co., of Sheffield.

First, a series of cast-iron shells, 300 lb. each, were fired at different ranges, and then shells made by Krupp were fired at the 4½-inch armour plates. The first shell, of hard cast steel, was 22½ in. long (two and a half diameters), with a flat end 4 in. in diameter. Fired with 50 lb. of powder at 700 ft. distance it passed through the plate, oak and teak backing, and broke into many pieces, although filled with sand only. The second and third shells were also of Krupp's steel, the same length, but with 6. in. ends. These shells pierced plates, wood, &c., and also went to pieces, although only filled with sand. The fourth shell was made by M. Poteleff, of puddled steel, on Aboukoff's system, the same dimensions as the second and third, and went through iron, teak, &c., but was only bulged up from 9 in. to 12 in., and the end flattened; not a single crack being visible in the shell. The fifth shell, the same as the fourth, passed through iron, teak, and the second target, and went at least a mile beyond. The sixth and seventh were from Krupp, and were charged with powder; they were quite flat-ended, 9 in. diameter. One exploded in the plate, the other in the wood. The eighth and ninth shells, were of cast iron, and, although they passed through the plates, were of course destroyed. Evening prevented further trials, which will yet be made on the same plate.

The results on the plate were highly satisfactory. In a space of 4 ft. 6 in. by 3 ft. 6 in. eight holes were made without any crack of the slightest description; and the marine officers present were highly satisfied, because they are obtaining 4,000 tons of plates from Messrs. John Brown and Co. for their different ships.

The English Government would do well to note the progress the Russians are making in gunnery. Cast steel guns are decidedly before any yet produced in England of any other metal. The 9 in. gun of Krupp has been fired with 300 lb. shells and 50 lb. of powder about 70 times without any flaw, and the Russian Government will shortly be in a position to obtain in St. Petersburgh a large supply of cast-steel guns, made from Russian iron, by Russians, on Aboukoff's system, which is very near the same as Krupp's.

THE DUMMY ENGINE.

The public prejudice against street railways has been overcome; and the communities now enjoying their advantages would look upon the removal of the roads as an invasion of their rights. There is one other prejudice to be removed; and until it is, the mission of the street railway will not be perfectly fulfilled. Property owners along railroad routes object to the use of the "dummy," or noiseless steam engine. The railway companies themselves share in the antipathy. This is no novel fact; for the very parties to be most benefited by any great new inventions, have usually opposed most fiercely their introduction. The "dummy" engine has been thoroughly tested in several parts of our country, and has everywhere proved an unqualified success. In New Jersey, from Jersey City to Birgen Point, it has undergone the practical trial of several months' daily use, and has demonstrated these facts:—That one small engine, occupying no more space than a chest of drawers, in the front partition of the car, and entirely concealed from external view, will draw as many passengers as ten horses; that it will draw them two or three times faster than horses, if necessary; that the expense, including wear and tear, is less than that of horses; that the engine throws no sparks in the air, consumes its own smoke and makes no noise; that it can be stopped in less space than a horse can, removing thereby liability to accidents; that the roads are kept in a cleanlier state; and as the business of the road has been increased since the introduction of steam passenger cars, that passengers prefer them to horse cars. The greater cleanliness of the streets is a stronger reason for adopting this kind of car in cities than in less populous places, but is of little weight in comparison with the saving of horse-flesh and the consumption of feed which would result from the general introduction of these cars. The saving of the feed of the horses now required for railroads, would cheapen the cost of feed. Pennsylvanians are interested, as a new source of consumption for the product of their coal mines would be presented. Those who, as legislators or acting in other public capacities, plane the way for and remove obstacles to the successful introduction of steam passenger cars will, when greater facilities are afforded for travel, and fares cheapened, be regarded by the public as benefactors.—*Phil. Ledger.*

WILDE'S ELECTRO-MAGNETIC TELEGRAPHS.

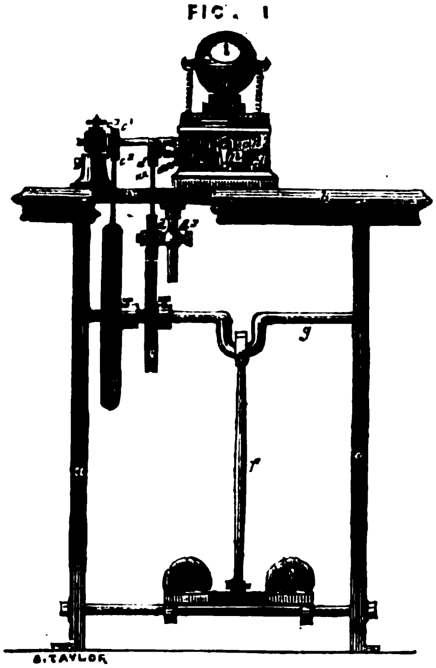

FIG. 3

FIG. 4

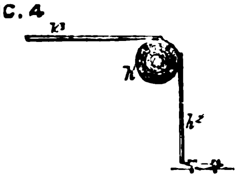

FIG. 7

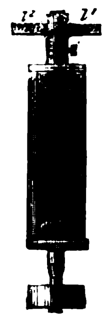

FIG. 2

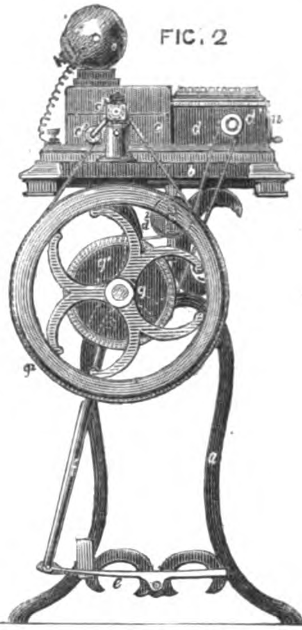

FIG. 5

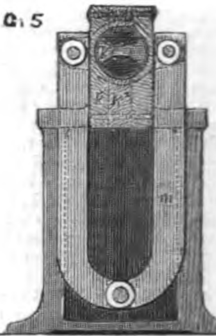

FIG. 6

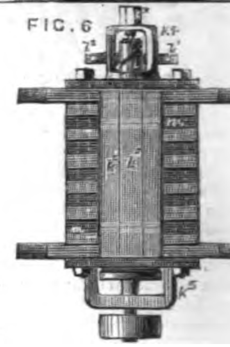


WILDE'S IMPROVEMENTS IN ELECTRO-MAGNETIC TELEGRAPHS.

LETTERS PATENT have been recently granted to Henry Wilde, engineer, of Manchester, for improvements in electro-magnetic telegraphs. This invention consists in improvements in the transmitting instruments described in the specification of Letters Patent granted to Mr. Wilde in the year 1861.

In the specifications of these patents transmitting instruments are described, in which the armature of a magneto-electric machine is mechanically geared with a radial arm, which travels beneath a series of finger-keys, any one of which being depressed arrests the motion of the radial arm, and also the motion of the armature with which it is mechanically connected.

In the present improvement the alternately "inverted" currents (or currents passing in opposite directions) generated during the continuous revolution of the armature of a magneto-electric machine are made to pass in one and the same direction by means of a "commutator" or current changer of the ordinary construction placed on the armature or other axis connected with the ends of the wires in which the currents are generated. These "direct currents" are then transferred by means of wires to another commutator, by which the currents are again inverted previous to their passing into the telegraphic circuit. This last-mentioned commutator is made to revolve more slowly than the other, so as to allow a greater number of the direct currents from the first-mentioned commutator to pass into the telegraphic circuit before the currents are again inverted. From the relation which the more slowly moving commutator bears to the more quickly moving commutator of the magneto-electric machine, it is called a differential commutator. This differential commutator is fixed on the axis which carries the radial arm and index finger of the transmitting instrument, and is so constructed as to invert the direct current from the other commutator as many times as there are letters or signs on the dial of the indicating instrument.

Fig. 1 is a front elevation of an alphabetical dial telegraph, to which the improvements are applied; fig. 2 is an end view. *a*, *a*, are the standards, and *b* the table on which the magneto-electric machine *c*, and the transmitting instrument *d*, are placed, which are driven by a treadle, connecting link, and crank shaft *g*, on which is fixed the pulley g^1 for driving the pulley d_1 fast on the commutator shaft *h* of the transmitting instrument. The tension of the band passing around the pulleys is regulated by the pulley d^2, mounted on a stud which is adjustable on a slide pillar.

The transmitting instrument is similar to that patented by Mr. Jacob Brett in 1848, with this exception, that in the present arrangement the currents are inverted by means of the "commutator" *h*, seen best in figure 4, whereas in Brett's patent they were only interrupted by means of a make and break wheel.

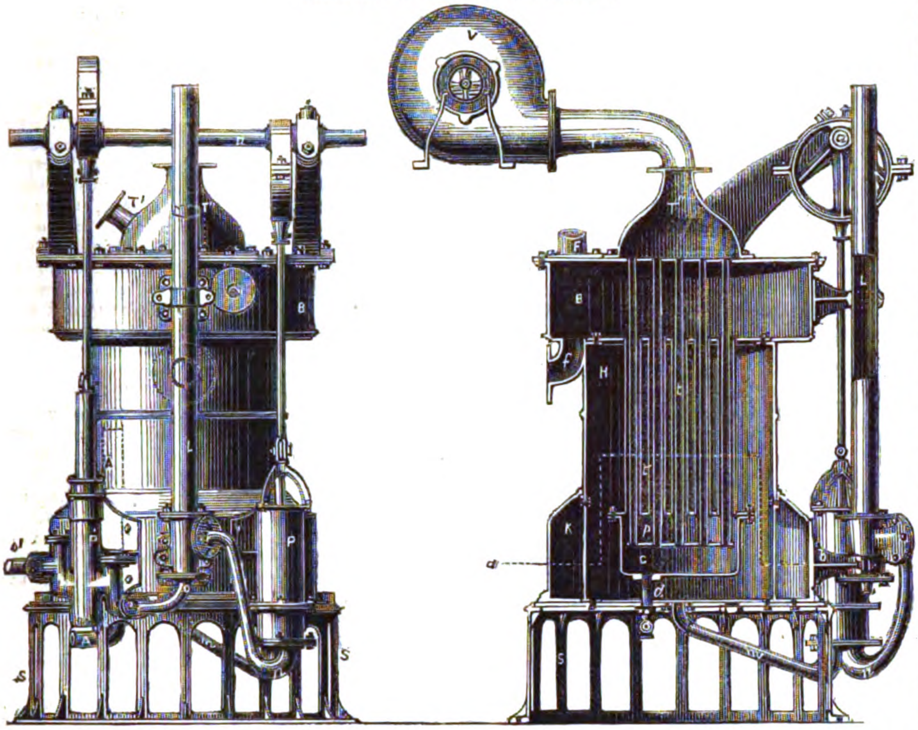
In the present arrangement the radial arm travelling beneath the finger-keys is driven by a worm and worm-wheel. The springs h^2 and h_3 are respectively connected to the line and earth wire terminal screws *j* and j^1.

The magneto-electric machine is shown in detail in figs. 5, 6, 7; in these views it is shown supported in a frame for the purpose of being driven by a separate moving power, whereas in fig. 2 it is attached to the table, and it is driven by the same moving power as the transmitting instrument. The cylindrical soft iron armature *k* is grooved at each side to receive the coils of insulated wire wound in the direction of the axis of the armature, and the armature shaft *i* is connected to the armature *k* in the usual manner; to the other end of the armature is connected the stud of the "commutator" *l*. This commutator is formed of two cylinders of hardened steel insulated from each other, and instead of being cut parallel to the axis, is cut diagonally in order that it may run more freely over the springs bearing upon it; the armature *k* revolves in a cylinder formed of the two outer pieces of iron k_1 and the intermediate piece k^2, made of brass or other non-magnetic substance, and the bolts by which the three pieces are connected are also made of non-magnetic substance. The horse-shoe magnets *m* are connected to the iron pieces k_1 by bolts. The armature *k* is kept concentric with the commutator end of the magnet cylinder by the tail pin k^3 passing through the brass cross piece k^4, and at the other end by a conical shoulder on the shaft passing through the brass cross piece k^5. The end of the armature shaft *i* is supported in an adjustable bearing to keep the armature concentric with the magnet cylinder. The switch *n* when turned against the stop n_1 short circuits the coils of the magneto-electric machine until the crank shaft *g* has acquired its regular motion, after which it is again brought into the central position shown in fig. 1, and the coils are then in direct communication with the line wire and indicating instrument *o*.

The mode of operation is as follows:—Motion is given to the armature *k*, which produces two currents or shocks for each revolution; these currents after being made to pass in one direction by the commutator *l*, are transferred by means of the springs and wires l^1 and l^2 to the spring l^3, and to the metal base of the transmitting instrument, which are respectively in connection with the separate and insulated parts of the commutator h^1; motion is also given simultaneously to the commutator h^1, and the relative speed of the commutator *l* and the commutator h^1 is such that the currents proceeding from the magneto-electric machine are produced about one-fourth faster than they are inverted by the commutator h_1. When the magneto-electric machine is driven by steam or other separate moving power the currents may be produced relatively faster than is necessary when the magneto-electric machine and the transmitting instrument are driven by the same moving power, for the purpose of keeping the speed of the former in excess of the latter when the most expert operator is working the instrument. Wires are connected from the place where the magneto-electric machine is driven to the transmitting instrument *d*, which is driven by the treadle *e*, as above described.

When the machine, shown in figs. 1, 2, 3, and 4, is in operation, the inverted currents from the commutator h^1 pass into the telegraphic circuit and act upon the indicator *o*, until the radial arm is arrested by the depression of a finger-key which stops the commutator h^1, and prevents the currents from the commutator *l* of the magneto-electric machine from being inverted. These currents then pass into the telegraphic circuit in one direction only, and from the well-known construction of the magnetic apparatus connected with the indicator which requires inverted currents to produce the rotary motion of an index around the dial, the direct currents from the magneto-electric machine will not produce any effect on the indicator, and the index of the indicator will therefore remain opposite the letter required so long as a finger-key is pressed down. When the pressure of the finger is removed from the key, the commutator h^1 again inverts the currents which actuate the indicators until the commutator is again stopped by the depression of another key. During the depression of a finger-key the band slips over the pulley d^1 in the usual manner, while the driving shaft *g* and armature *k* continue their motion as before.

DATICHY'S STEAM ENGINES.



DATICHY'S IMPROVEMENTS IN STEAM ENGINES.

THE object of this invention, patented by Jean Datichy, of London, engineer, is to utilize the steam after it has produced its effect in the cylinders of steam engines, by passing it into and through condensing apparatus, consisting of tubes surrounded by water alone, air alone, or by air and water, the air being forced in by a fan or blast, and the water, when water is used, being allowed to trickle down the outside of the tubes in a case surrounding them, which water rises, overflows, and entering a double casing, escapes, and is returned to the supply cistern. The steam being more or less condensed, is forced by suitable pumps into the boiler directly or through a coil in or round the casing of the boiler, whereby it becomes heated before entering the boiler. The condensers consist of jacketed cylinders, containing within them another casing, in which are tubes, into which the waste steam from the cylinders is made to enter; or the patentee reverses the position of the steam and of the air and water, or air or water—that is to say, he causes the air and water, or air alone, or water alone, to pass through tubes contained in a casing or cylinder into which the steam to be condensed is admitted.

Fig. 1 of the accompanying drawings is an elevation, and fig. 2 a section through the line *c*, *d*, of fig. 1, of a condensing apparatus and parts connected therewith, constructed according to this invention.

H is a chamber in which the condensation of the waste steam is effected; A is a pipe leading the waste steam into the chamber H; V is a fan for forcing in air; and T, the fan pipe; T^1, fig. 1, pipe for the introduction of water; T^{11}, reservoir for air and water; *t*, *t*, *t*, are tubes through which the air and water descend into a receiver G; *p* is a perforated plate separating the tubes *t*, *t*, *t*, and through which the air and water re-ascend into other tubes t^1, t^1, t^1, encasing the tubes *t*, *t*, *t*, and which lead the air and water into an outlet case or chamber B; F is a pipe for the escape of the air, and *f* a pipe for the passing off of the water; K is a chamber protecting the bottom of the chamber H from contact with the external air; P is a suction pump for the condensed steam, and *m* the suction pipe of the same; *n*, force pipe of the pump P; L, atmospheric column; P^1, pump for forcing the steam into the boiler; O, suction pipe on the column L O^1, pipe through which the condensed steam is forced into the boiler; *a*, shaft for the transmission of motion; S, frame supporting the apparatus; *d*, emptying cock of the receiver G of the tubes *t*, and t^1, and of the case B; D, emptying plug of the chamber H.

The action is as follows:—The steam from the cylinders of the engine enters the chamber H through the pipe A, and becomes partially condensed by immediate contact with the tubes t_1, which are kept cool by a current of a mixture of air and water, or air alone, or water alone. The air is forced in by the fan V through the pipe T, and the water enters by the pipe T^1. The air and water become mixed in the reservoir T^{11}, and pass therefrom together into and through the small tubes *t* into the receiver G, and re-ascend, through the perforated plate *p*, into the tubes t^1, from which they pass into the case B, which has two escape pipes; the air and water pass off by these pipes into a reservoir provided for the purpose, and is returned to the supply cistern. The condensed steam is drawn from the chamber H by the pump P through the pipe *m*, and is forced through the pipe *n* and column L, while at the same time the pump P^1 draws it through the pipe O into the pipe O^1, which leads it to the boiler; this pipe O^1 is coiled or of serpentine form, and the patentee prefers to place it in stationary and marine engines in front or behind the furnace, and in locomotive engines in the smoke-box, by which means the water or condensed steam becomes re-heated before entering the boiler.

BROWN'S IMPROVEMENTS IN THE MANUFACTURE OF ARMOUR PLATES.

THE following improvements in the manufacture of armour plates have been recently patented by Mr. T. Brown, of Sheffield, being a communication from Alexander Holley, of New York:—This invention has for its object improvements in the manufacture of armour plates for ships and other structures. For these purposes plates of wrought iron are piled one on the other, having between them crushed or pulverized franklinite, spiegel iron, or similar metal; this pile is heated to a suitable degree to cause the franklinite, spiegel iron, or other similar metal to assume a pasty or melted state, and the wrought-iron plates to be brought to about a welding heat, so that when rolled or pressed the parts of the pile will combine. The rolling is to be continued till the mass is reduced into a plate of any desired thickness. A series of such compound plates are piled one on the other with pulverized franklinite, spiegel iron, or other like metal between them, and this pile is to be heated and rolled, or pressed, and reduced to the desired thickness, either for an armour plate, or for being again piled with other plates, as above explained Fluxes may be used when found desirable.

AN ENORMOUS PAIR OF SHEARS.

MESSRS. TANGYE, BROTHERS, AND PRICE, of the Cromwell Works, Parade, have just completed, for the Russian Government, an immense pair of shears, weighing four-and-twenty tons, having a power of pressure equal to a thousand tons, and able to snip to pieces a cold bar of iron half a foot square. The contrivance is technically described as a "horizontal hydraulic shearing machine, with open mouth;" and it is said to be, if not the largest, at least, the most powerful article of the kind ever made. The cylinder is of wrought iron, and is hooped to increase its strength; it may be removed, and used as a hydraulic press of a thousand tons power; the machine is fitted with valve arrangements to reverse itself at any length of stroke; may be set to cut iron from ½ in. thick to 6 in. thick; when at full power it will cut a bar of iron 6 in. square in forty seconds; the return motion is six times as fast as the cutting motion. To this it may be added that the casting weighs eighteen tons, and that the fittings weigh about six tons. The piston is of cast iron, and is 16 in. in diameter; and it fits into a square block of wrought iron, which carries one of the cutting blades, the other being fixed into the solid casting, and both being 14 in. long, 11 in. deep, and 3½ in. in thickness. The blades are of hardened cast steel. The force-pumps for the machine work on the horizontal principle, and are so arranged that they can be set to any power, and being set to that power cannot go beyond it, but as soon they reach it retreat. The machine is made for the Russian Government, and it is intended to be used as a "scrapping machine" in a large ironworks in the neighbourhood of St. Petersburgh. To the unlearned in such matters the machine looks for all the world like some mechanical behemoth, or an immense megetherion, resuscitated from the fossil state by galvanism, and set to work for the benefit of us moderns. It is a great deal bigger than an unusually large elephant, and not half so comely in its proportions. Its jaws, so to speak, are at the nape of its neck—two broad edges of steel standing upright, and facing each other. One of them only can be moved, and that is moved in this way:—Along the animal's back runs a huge backbone of iron—round, solid, and capable of sliding backwards and forwards. To this backbone is affixed, between the shoulders, a square block, also of iron, and also moveable, and into this block is fixed the jaw of solid steel. All you have to do, therefore, is to push the backbone at the end farthest from the jaw, and the jaw at once moves forward in the direction of its opposite neighbour. The pushing is done by water power—a power so great, that dropping a solid bar of iron 6 in. in thickness into the creature's mouth, and thrusting the jaw forward, either the bar of iron must come in sunder, or the jaw break and the animal itself fall in two. There is no resisting it. The power is awful, and the resistance of the solid parts of the animal and its steel teeth scarcely less so. We saw it yesterday. It crunches up iron like we mortals crunch up a salad. If it break the machine, the pieces will fall there and do no distant damage; you can take off the power instantly, and there is no momentum to do further harm. So much as to the machine itself. Comparing it with others it is doubly as powerful, so we are told, as any machine of the kind previously made—that is to say, that while nothing has ever yet been invented that would cut a bar of more than 3 in. in thickness, this will cut one of 6 in. The body of the machine, the solid casting—and it is all in one piece, excepting the moveable parts to which we have referred—is made of cannon lost in the sea during the great siege of Gibraltar by the Spaniards; so that guns used to decide the fate of nations, and lost during one of the most famous sieges in modern history, have been fished up from the bottom of the sea and fashioned into shears to cut old iron to pieces for the furnace. Truly, we may say with Hamlet, "To what base uses may we come, Horatio!"—*Birmingham Post.*

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post-office orders made payable to Mr R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

RECEIVED.—T. B., W. T., C. K., J. E. C., L. K., B. F., B. M., R. O. L.

P. M. (Birmingham).—We believe there would be a decided advantage in the use of lead instead of zinc as you propose, but all attempts to coat iron with lead in a satisfactory manner have hitherto failed. If you can really do all you state, your invention should be very valuable.

T. WALKER (Birmingham).—We do not understand your question: do you mean feathering paddles? We have seen models of wheels in which the floats were always vertical, but we know of nothing of the kind in actual use. If you will be a little more explicit, we will endeavour to get you the information you want.

T. W. B.—You will find the slide rule answer your purpose, perhaps, better than anything else. A few hours' instruction would enable you to understand it sufficiently for your purpose. There is no such book as you want for sale at a small price.

ERRATUM.—In the article on "Cleaning Ship's Bottoms," which appeared in our paper last week, for "Mr. M. Hutchinson" read "Major-General Hutchinson."

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In your leading article of the 9th inst., on Twin Screw Steamers, it is stated that Capt. Carpenter only used one engine. Permit me to say that this is a mistake, for in the year 1851 I made the machinery to his order and from his plan, for three models 3 ft. 6 in. long. This consisted of two separate engines, one to each screw, and working entirely independently of each other.

Capt. Carpenter gave me these reasons for adopting this plan:—1st, the screws could be used to steer with; 2nd, that by reversing them the ship could be turned on its own centre. These things the model fully illustrated. In his printed circular, which is now before me, he says:—"The shafts lie in a line with the direction of the keels to each propeller, with a connection to the engine or *engines*."

My apology for writing to you, Mr. Editor, is that the captain is dead, therefore cannot answer for himself; and as I know that you are always most anxious to award the honour of an invention to those to whom it is due, I venture to hope that you will find room for this, or a portion of this letter, in your valuable journal.

I am, Sir, your obedient servant,
HENRY CHAPMAN.

Correspondence.

GUNNERY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Your correspondent "Civilian" hopes that, in putting forward his opinions on gunnery, he is not presumptuous; his object being, he says, "to promote discussion and elicit truth;" and undoubtedly his communications do tend to *provoke* discussion at any rate. I am honestly of opinion, that "Civilian" would make a very useful writer on practical matters, if he would only take the trouble to ascertain the extent and character of what has already been determined concerning the theme on which he writes, and not substitute his own fancies for its acknowledged scientific principles. As an example—referring to his communication last week—of the direction in which knowledge and self-improvement may proceed, the following opinions, as revised and amended by him, will suffice. They are these—that "the momentum of projectiles" is *not* "in the ratio of the square of velocity multiplied by the weight"—that *vis viva* is *not* a synonyme for velocity, nor *vis inertia* for weight—that *vis viva* is not "a more important element than weight," seeing that weight is one of the constituents of this so-called element, the other being that law of the velocity which he ascribes to momentum—that the products of weight into the square of the velocity, when "giving equal quantities, ought [*not*] to indicate equal effects" in the way of penetration by shot, unless the areas of impact are equal—that the inequality of effects as found in practice is owing to a want of similarity in this circumstance of the case, and *not* to "a more important element than weight" misnamed *vis viva* and velocity indifferently—and that "the long range at which the Charleston forts have been shelled is [*not*] simply ascribable to the application of the rifle principle," but to the application of rifling to guns, merely as a practical expedient, to secure the parallelism of a long projectile to the end of its flight; the greater extent of its range, in comparison with a spherical shot, being due, *not* to its revolutions on its axis, but to its greater weight, and to its encountering no greater resistance from the atmosphere, probably, than the ball. With the same charge of powder the velocity will be less, but the projectile force will be greater, as measured by momentum, and still more so, as measured by *vis viva*, and therefore it will go further and strike harder as well.

With these revised opinions and improved ideas, "Civilian" may be able, perhaps, to see his way clear to this conclusion, although hitherto he has been opposed to it—that a heavy shot with moderate velocity, and a lighter shot with a greater velocity, may each be equally efficient in destructiveness, when to each is appointed the special task it is fitted to perform; the work of the one being a general smash of the defences, and that of the other a clean perforation through them all. This conclusion relates to differences in weight and velocity even under the same form, whether spherical or elongated. "Civilian" confounds the smashing and penetrating effects of shot, and speaks of them as though they were referable to the same conditions of the problem, and he does so because he neglects to take momentum and the cross section of projectiles into consideration. In simple penetration, there is a more special relation to the power of *vis viva*; but when materials in masses are forced bodily away, momentum is chiefly concerned in the effect, and a greater area of impact will here assist rather than interfere with the action. If this dimension for each projectile be the same, and the amount of *vis viva* be also the same, then, the conditions being alike and the causes being equal in this particular aspect, the effects in the same aspect will be alike for each; that is to say, the effects will be alike, so far as things that are proportional to the mass and the square of the velocity are concerned. For things are proportional also to the mass and the simple velocity, and in regard to these we must recognize momentum as the measure of the cause, or, rather, of the cause in this its governing aspect.

If, however, a course of experiments after a careful interpretation of them, embracing all their circumstances, should satisfactorily determine that a deeper penetration attends the superior velocity, even when all the *vis viva* quantities are equal, then the case is lost to investigation in a very obscure subject, concerning the varying powers of resistance by materials in some relation to the time of the impact—a subject about which I can say nothing at present, and of which nothing has been said by anybody, so far as I know. It is a species of physics which does not at present admit of mathematical formulæ, and, very probably, it never will. Something may be learned in the way of experiment; but the experimenter, like Professor Faraday, in his experimental investigation of gravitation, will most likely be foiled by the faint evanescent and infinitesimal character of the results, defying the power of the most delicate instruments of research. We should want something equivalent in sensibility to the spectral analysis. But about the experiments on impact just referred to, and all their attendant circumstances, "Civilian" may depend upon it that, among those circumstances, the most important will have respect to the similarity of the conditions concerning the rigidity or the yielding of the materials, whether such yielding be of an elastic or non-elastic character; for, of course, everything else being the same, the penetration will be the deepest where the material is most immoveable. A word to the wise is enough.

Yours, &c.,
BENJ. CHEVERTON.

October 19.

BOILER EXPLOSIONS.

SIR,—In connection with what has lately appeared in your columns relative to the origination of the percussive theory of boiler explosions, you will, perhaps, permit me to point out how far it has been misapprehended in the attempt to reproduce it in the article "Steam Engine," in the last edition of the *Encyclopædia Britannica*, where the "Great Eastern" explosion is explained as follows:—"The chimney, being unstayed, collapsed like a flue, under the pressure on its outer surface, and thus occasioned a sudden enlargement of volume within the heater, and a simultaneous reduction of pressure; the steam suddenly and spontaneously generated expanded against the collapsed flue, and rebounded on the casing, projecting water with it. The moving mass of water and steam, thus suddenly arrested, expended its momentum on the casing and rent it asunder."

The unstayed chimney must necessarily have collapsed like a flue, and under a moderate pressure, as was first publicly pointed out in the *Engineer* at the time of the accident. Your own columns of October 14, 1859, show how my opinion to this effect was then controverted. In the collapse, one or more seams of rivets in the chimney would be almost certain to be ruptured—a fact which none who are familiar with the condition of collapsed boiler flues can doubt. This rupture would permit the sudden escape of the free steam, thereby partially removing the pressure upon a large quantity of heated water—for from the conditions under which the heater was worked, it must have been nearly full of water at the moment before the chimney collapsed. The consequences of suddenly removing, from the surface of many tons of water already heated to perhaps 300 degs., a large portion of the pressure under which alone that temperature could be attained, would, clearly enough, be violent, although the precise condition which the liquid mass would assume in eruption has not yet been ascertained.

In the extract, however, already quoted from the *Encyclopædia*, the indispensable fact of rupture, as a consequence of collapse, is overlooked. The mere "enlargement of volume within the heater" is assumed as the cause of a "simultaneous reduction of pressure" upon the heated water. But it is doubtful whether the collapse of the chimney could have been more sudden than the disengagement of additional steam from the water, and of a pressure due to its temperature. The collapsed portion of the chimney weighed more than five tons; and in collapsing a great strain would be brought upon extensive sections of iron, even did not the chimney, upon a slight change of form, bulge out on two sides and strike the walls of the outer casing. I will not, however, press this point; but, for the sake of argument, I will assume that the collapse was inconceivably sudden, thereby "enlarging the volume within the heater" quicker than either steam, or water, or both together, could follow. This, of course, is assuming an impossibility, since the chimney could not have collapsed *sponte sua*. If steam burst forth by itself from the water, I will assume that its rate of motion was, say, 1,700 ft. per second; or if the heated water was projected *en masse*, that it would have a corresponding velocity of 85 feet per second (taking the "relative volume" of the steam, of say 56 lbs. above the atmosphere, compared with water, as 400). The water being already everywhere in contact with the inner surface of the outer casing, the blow would be delivered towards the centre. But at the instant when either steam or water, or both combined, began simultaneously to move inwards, the moving particles would be compressed against each other, like the voissoirs of an arch or the staves of a tub. If the inward movement be assumed as absolutely simultaneous from every point in the inner circumference of a truly circular casing, then, neither steam nor water could possibly reach the centre, since they would wedge fast on the way. Allowing even for a considerable irregularity of form in the casing, it is difficult to conceive of anything like a concussion of steam or water at or near the centre. In any case, it i

to be remembered that the outermost particles of water, or those already in contact with the casing, would, so far as the inward movement was concerned, remain practically stationary, and that those next within them would move but slightly. It is not to be supposed, that the heated water, in an annular casing of 7 ft. outside and 6 ft. inside diameter, could be gathered, by its own stored-up energy, into a central pillar of equal sectional area, or 3 ft. 7½ in. in diameter. Such a pillar could not be formed, and, therefore, there could be no "rebounding," as is gratuitously assumed in the *Encyclopædia*. Even were a violent rebound possible, the casing would have been burst only radially outwards, and it would not have been lifted, as it was, along with the chimney, many feet into the air and thrown over upon the deck. Under the actual circumstances of the case, no enlargement, however sudden, of the volume of the heater could, in the absence of a rupture, and, thereby, an outlet for the free steam, have produced either a diminution, or an exaltation of pressure upon the inner surfaces of the casing. In other words, the explanation, given in the *Encyclopædia*, of the "Great Eastern" explosion, and of which a correspondent in your impression of the 9th inst. speaks as "a plain and instructive illustration of my projectile theory," is physically impossible.

I am, Sir, your obedient servant,

ZERAH COLBURN.

3, Upper Bedford-place, Russell-square,
October 19, 1863.

FLYING AND FLYING MACHINES.

SIR,—I have a very curious proposition for some of your clever readers to solve. A gentleman, whom I suppose you know very well, having written a good deal in the MECHANICS' MAGAZINE about flying and flying machines—in order to enable him to make a complete model, I have given him permission to test his ingenuity and mechanical skill by letting him use a lathe and tools for the purpose of testing the thing, as I tell him it is a pity to see time wasted by useless means for proving the subject. I asked him the other day, that, supposing he accomplished his desire, what did he mean to do? he said, fly to Australia: by doing so, and flying against the rotation of the earth, he could be there in a few hours. My proposition is, Why fly at all?—because if you can keep up 24 hours without being influenced by the rotation of the earth, you will have nothing to do but when Melbourne comes round to drop into it, supposing you are in the right direction; if this was so, it would not be a matter of flying, but simply waiting. Think it over, and see what you can make of it.

Yours truly,

J. W.

[In compliance with our correspondent's request, we have thought the matter over, and this is what we make of it:—The circumference of the earth is about 24,000 miles. The atmosphere moves with the earth, fortunately for us. Any balloon, &c., suspended, as he proposes, would be exposed to a current of air moving at 1,000 miles per hour. The speed of the blast in the most violent tropical tornadoes, seldom exceeds 100 miles per hour. J. W. may imagine the effect of a current moving with ten times that velocity.—ED. M. M.]

Miscellanea.

The line-of-battle ship launch, which has been fitted by the steam factory department of Portsmouth Dockyard with a pair of small engines, driving two four-bladed screws, realized on her recent preliminary trial at the measured mile in Stokes Bay a speed of 6¼ knots, and was found to possess the same power of turning upon her own centre that has been exhibited by larger vessels in recent trials of twin-screws on the Thames. A more complete trial of the boat's capabilities will be made shortly.

The Australian papers speak of a discovery, of some importance, made on the north-west coast of that continent by Captain J. Jarman, of the "Tien-Tsin." This vessel was fitted out for an expedition up the coast in question, and was accompanied by a Mr. Padbury, of Perth. The result has been the discovery of a fertile region, with well-sheltered harbours, having a rise and fall of tide of some 16 ft., and of a valuable island, named after the discoverer, Jarman Island. Captain Jarman has, moreover, it appears, drawn up a chart of the coast from Cape Lambert to the Sherlock River, with soundings of the entire line and of the harbour of Tien-Tsin, so named after the vessel under his command. There can be no doubt that Captain Jarman's labours will form a valuable contribution to geographical and hydrographical knowledge.

A naval officer has offered the following solution for that tough geological problem, the origin of basalt. He thinks that the columns never were lava, or molten matter of any sort. Wherever naturally ball-and-socket jointed columns are exposed to view in cliffs, or in separate groups, or mounds, in plains far away from volcanic districts, there the bamboos, from which the columns derive their form and features, really did grow. The fact of coal, fossil wood, and pillars of basalt being so often found in contact, one above another, or side by side, arises from the simple fact of their having all once been growing vegetable matter. Instead of basaltic columns being protruded upwards through the coal beds, the bamboos which formed those columns grew before the surrounding horizontal or overlying strata of coal or other matter were formed.

Spain is not behind the rest of the countries in Europe in war expenditure this year. The army and navy expenses for 1863 show an augmentation already of eighty millions of reals, originating, doubtless, in some measure from the expedition to St. Domingo.

It appears by a communication from Ajaccio that the cultivation of cotton has been successfully introduced into the island of Corsica by Count Bacciochi. The Count generously placed one of his farms in the neighbourhood of Ajaccio at the disposal of a manufacturer, who offered to make a trial of the cultivation of cotton. The experiment succeeded so well that it has been extended to several other parts of the island, and the result has exceeded the expectations of the planters. Samples of the cotton cultivated in the island of Corsica have been sent to Paris for exhibition.

Messrs. Scott and Co., of Cartsdyke, launched a beautiful steamship last week, the second of eight being built by the same firm, for the French Transatlantic Steam Navigation Company, which was gracefully named "Lafayette," by the wife of C. H. Dunlop, Esq. The "Lafayette" is 3,400 tons, builders' measurement, and of the following dimensions:—Length, 350 ft.; breadth, 45 ft.; depth, 33 ft. She has four decks, the upper being flush from stem to stern, and the three lower having each a height of 7 ft. 3 in. She will have accommodation for 300 first-class passengers, hold capacity for 1,000 tons of goods, and will be able to stow 1,500 tons of coal in the bunkers. Her machinery will be furnished by the Greenock Foundry Company, and will consist of a pair of side lever engines of 850-horse power nominal, with levers of malleable iron. The cylinders are 95 in. in diameter, with 9 ft. 6 in. stroke. The boilers, four in number, are tubular, each of the weight of 61 tons, and each sole plate weighs 55 tons. The paddle wheels will be 37¼ ft. diameter. The "Lafayette" is the largest steamship ever built in Greenock; is sister to the "Washington," launched by the same firm on 17th June last. The third ship will be ready about the end of December. The five other ships are being built in yards erected by the Messrs. Scott in St. Nazaire, in France.

It is stated from Frankfort that a patent has been taken in England and in most of the Continental States for a peeling and cleansing machine of all kinds of pulse, by which a great saving of time and an increase of the produce of flour will be secured. The proprietors of the largest flour-mills in Switzerland state that the old problem of peeling pulse is now solved, and that they are fully satisfied with the new machine. The bran has proved to be available for paper fabrication.

A model of a proposed plan for the storage of petroleum in the original casks, without leakage, and as a consequence removing the liability to smell, was shown on Friday, at the office of Messrs. Holt and Banner, Sweeting-street, Liverpool. Without going into details we may mention that the leading features of the plan are the sinking of the original barrels in cisterns or tanks of water, so that they may always be submerged. The barrels are introduced into the wells by a shaft wit[illegible] greatest facility, and when required can [illegible] recovered. The wood barrels being ke[illegible] the water would, it is contended, swell them so as to render leakage impossible. The wells or tanks could be constructed of brick, or in any other way, so that they are capable of containing a sufficient quantity of water. So far as can be judged by the model, the plan appears to possess considerable merit, and is worthy of attention now that the question of doing away with the smell from petroleum is brought so prominently under public notice.

On Monday, Her Majesty's ship "Tweed," laden with the last consignment of the telegraphic cable about to be laid down over a length of 1,200 miles, from the mouth of the Persian Gulf along the sea coast to Mekra, left the works of Messrs. Henley and Co., the contractors and manufacturers, at North Woolwich. The cable, which has been constructed for the India Office, under the superintendence of Lieutenant-Colonel Stewart, of the Royal Engineers and India Office, Public Works Department, in conjunction with Sir C. Bright and Mr. Latimer Clark, the engineers and electricians, has been twelve months in process of manufacture, and is understood to be the most complete cable as yet produced in this country. The core consists of 225 lbs. of copper wire and 275 lbs. of gutta percha per nautical mile, covered with tape, and has been prepared by the contractors, in lengths of about 3 nautical miles, at the works of the Gutta Percha Company, in the City-road. Everything has been prepared in the way of insulation, jointing, covering, and serving by the most experienced workmen. The core is covered with Russian hemp and Stockholm tar. The iron covering for the main cable consists of 12 (No. 7 gauge) galvanized iron wires, and the iron covering for the shore end of the cable consists of 12 (No. 2 gauge) galvanized iron wires. As regards the external coating of the cable, it has been covered, after the iron wires were laid on, with two coatings of mineral pitch and Stockholm tar, and then alternately with tarred hemp and yarn, and all covered with Chatterton's compound. The entire cable, which has been manufactured at the rate of 50 nautical miles per week, has been thoroughly tested by the engineer, who, with Colonel Stewart, are to follow overland at the end of the month to commence the laying down and submersion of the line. The cargo of cable by the "Tweed" makes the fifth shipment within the last three months.

The Tyne and Clyde shipbuilders are likely to meet with a spirited opposition before long in iron shipbuilding from the Welsh ports. The Newport Wood and Iron Shipbuilding Company have purchased an extensive private shipbuilding yard at Newport, and arrangements are in progress with the view of building iron ships. The negotiations which have been going on for some time between the trustees of the Marquis of Bute and Mr. Scott Russell, have also terminated successfully, and the latter gentleman has entered into arrangements to establish an iron shipbuilding dry dock near the mouth of the Taff, at Cardiff. No time is to be lost in constructing the dock, as Mr. Scott Russell has accepted contracts for building three iron ships, and the same are to be completed within a specified period. From the proximity of both Newport and Cardiff to the coal and iron districts of South Wales, and the consequent cheapness of iron and fuel, it is believed that iron shipbuilding can be carried on so as to be able to successfully compete with the Tyne and Clyde shipbuilders.

Captain Ericsson has contracted to construct some 13 in. smooth-bore guns which are to have a much greater initial velocity than any now in use. He is to receive nothing for these guns unless they burn over 50 lbs. of powder—for every pound of powder beyond 50, Mr. Ericsson is to receive 5,000 dols. He is confident of being able to burn 100 lbs., and is certain of burning 75 lbs. The solid shot will weigh 220 lbs.

In Providence, R.I., there are 1,535 persons employed on Government work. One establishment alone employs 500 workmen on the Springfield rifled musket, and other factories are working with smaller forces on particular parts of the same favourite arm. An iron foundry employing 100 hands is now casting ordnance comprising 11 in. and 13 in. Dahlgren guns, with shot and shell for the same. A gun is turned off once in four days, and five tons of shot and shell are cast per day. The wrought-iron Ericsson [illegible] for the monster iron-clad "Dictator," [illegible] at New York, is to be bored an[illegible] ion at this place. After [illegible] ht to New York and it is be[illegible] ntendence of Captain [illegible] 6 in. in thickness.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

671. J. Tomlinson. *Improvements in machinery for opening twisted yarns and woven fabrics.* Dated March 11, 1863.

This invention consists in the application of two or more feeding apparatus to the main cylinder of the ordinary hard waste breaking and finishing machine, each feeding apparatus being fitted with two feeding rollers, or with one feeding roller and a concave trough. Each feeding apparatus can be adjusted so as to be brought closer to or further from the teeth of the main cylinder. The gearing for driving all the feeding apparatus is connected to a reversing motion, so as to be able to back out the feed of each feeder at the same time. *Patent completed.*

672. J. Renshaw. *Improvements in machinery for dressing, raising, and brushing silk and cotton velvets, velveteens, cords, plushes, and other piled fabrics.* Dated March 11, 1863.

This invention consists in causing the fabric to be operated upon to pass over and under two series of rollers, above which are mounted a series of circular brushes, to which a rapid revolving and a to-and-fro motion in the direction of their axes is given. *Patent completed.*

673. W. Rosseter. *Improvements in back-beam warping machines.* Dated March 11, 1863.

This invention consists in certain improved combinations and arrangements of self-acting machinery for stopping back-beam warping machines when a warp thread breaks or fails to be supplied, and also combining the dents and cross bars with spiral springs for expanding and contracting the reed or wraith to suit the warp, and in the mode of communicating motion to such machines. The invention cannot be described without reference to the drawings. *Patent completed.*

674. F. B. Kraushaar. *Improvements in apparatus for winding, cleaning, measuring, sorting, doubling, throwing, and reeling silk, parts of which improvements are also applicable to like machinery for spinning, doubling, and twisting cotton, wool, and other fibrous materials.* Dated March 12, 1863.

This invention relates to improvements upon and applicable to certain machinery and apparatus patented by Rudolph Bodmer as a communication from the present patentee, dated the 29th September, 1857 (No. 2508). These improvements consist—1, in certain mechanism for regulating the tension of filaments or threads of silk, cotton, or other fibrous material when the same are wound upon or off reels, bobbins, spindles, spools, and such-like objects in the various operations of winding, twisting, and doubling, and for which and other operations a uniform tension of the thread is requisite or desirable. This tension regulator consists of a bar rod or lever, one end of which is furnished with a suitable eye, hook, or other guide, through which the thread passes, and by means of which it is supported by the thread the tension of which is to be regulated, whilst the other end of the bar is joined to and forms part of a simple friction apparatus connected with the spindle, bobbin, or other object from which the thread is wound off, or with the spindle upon which it is wound, or with both. The regulator resting with one end upon the thread will by its weight depress it according to the amount of resistance to be overcome in unwinding it from its spindle, and cause it to deviate more or less from the direct line. If, therefore, an increase or a decrease in the resistance takes place, the deviation will become smaller or larger, and the regulator will rise or fall, and thereby decrease or increase the friction upon the spindles in connection with it. In this manner a constantly uniform tension of the thread will be maintained. In case of the strain becoming too great, the winding-on spindle will, by the same friction apparatus, be thrown out of gear with its driving disc or strap, whereby the breaking of the thread is prevented. 2, The improvements consist in self-acting or automatical weighing by sorting machinery or apparatus, intended chiefly for weighing and sorting bobbins or tubes of silk thread of equal lengths. *Patent completed.*

675. H. D. and J. W. Taylor. *Improvements in finishing woollen, worsted, and other fabrics, and in machinery or apparatus to be used therein.* Dated March 12, 1863.

This improved process or finishing operation consists in causing the surface or surfaces of fabrics requiring to be dressed to pass in contact slowly over, under, or between a flat, convex, cylindrical, or other dresser or dressers, while the latter are in rapid motion, so that the surface of the fabric is thereby subjected to a peculiar operation, the effect of which is to raise the pile or staple in the first instance, and then to reduce it by rubbing till the required finish is obtained, and finally to beat or cleanse the fabric from the pumex dust and other impurities. The object of this invention is to produce such a finish upon the surface of the fabric as shall render it immaterial in what way the same shall be cut and put together in the manufacture of any article therefrom. The pile or nap of the woollen, worsted, or other goods, instead of being raised and dressed in the usual way so as to lay in an inclined direction on the surface of the piece, is raised and reduced so as to form a short and even nap, standing vertically on the surface of the fabric. The machinery or apparatus which constitutes the second part of the invention, and by means of which it is proposed to effect the aforesaid finishing, consists of a dresser or dressers having pile-raising plates, rubbers, and beaters or cleansers, actuated by any mechanism suitable for the purpose, and the whole mounted in a proper frame fitted with feed and take-off rollers, by which the fabric is propelled. *Patent completed.*

676. L. Dessens. *An improved bath or bathing machine adapted for deep water.* Dated March 12, 1863.

This invention consists of two iron or wood frames fastened to each other by vertical uprights. The bottom and sides are supplied with nets of canvas or pieces of cloth, metallic grates, or wire gauze, in order to allow the water to enter into the bath. When the bather is seated in the bath, his whole body is immersed in the water in the ordinary bathing posture. The bath is prevented from sinking by means either of an india-rubber girdle inflated with air or by the application of cork or other suitable buoyant substance. The bather by turning a crank imparts a rotary motion to a screw placed at the head of the bath, and by pressing with his feet on paddles or treadles placed at the ends of a cross-bar fixed to a case, he is enabled to impart to the screw circular and horizontal motion, and thus direct the bath either to the left or to the right, or in a straight line, serving also the purpose of a rudder, according to the direction desired to be taken by the bather. *Patent abandoned.*

677. W. Clark. *Improvements in breech-loading fire-arms.* (A communication.) Dated March 12, 1863.

This invention is not described apart from the drawings. *Patent completed.*

678. E. H. Lomas. *Improvements in the action of charger or measure for powder-flasks, canisters, or other vessels.* Dated March 12, 1863.

This invention consists in the following arrangements:—Within the charger or measure, and near where it connects with, or is attached to the flask or other vessel, and at such distance from the outer end as will give the capacity or measure required, are arranged two discs of brass, or other suitable metal, the one fixed and the other moveable, both discs having openings so shaped that the spaces between the openings in the moveable disc will cover and close the openings in the fixed disc. But when the moveable disc, which turns upon a central pin or axle, shall have been turned round until the openings of both discs, which are made to correspond in shape, come together, then a communication will be opened between the flask or other vessel and the charger, which will allow the gunpowder or other substance to be measured or discharged to flow into the charger. And, when the charger is filled, the moveable disc will be brought back to its place by the means of a hoop spring of brass or other like suitable material. The turning of the moveable disc, so as to open the communication, is accomplished by acting with the thumb or finger on the end of the said spring, which is attached to the moveable disc by a pin or bar which works through a slot in the side of the charger, the slot being of sufficient length to allow the apertures in the discs to come opposite to each other by the moving of the moveable disc upon its central pin or axle. *Patent completed.*

679. J. Polkinghorne. *Improvements in treating tin ores, and in apparatus for treating ores and matters containing arsenic.* Dated March 12, 1863.

This invention consists—1, in treating tin ores as hereafter described. The patentee treats tin ores with rectified concentrated or diluted sulphuric acid and chloride of sodium, and keeps them in a heated state till the whole or nearly the whole of the iron, copper, and foreign matters and impurities are dissolved, or so reduced that they may be easily separated by washing. Four hours will generally be sufficient, but more or less time may be allowed. The progress of the operation may be ascertained from time to time by withdrawing a small portion from the furnace or pan and washing it in water, and then smelting the ore. When the ore has been sufficiently acted upon, it is removed from the furnace or pan to be washed in water to separate from it the soluble and insoluble matters and impurities it may contain. The invention consists—2, in an improved method of smelting tin ores. In order to free the metal contained in the ores, he mixes 20 parts by weight of the ores, containing about from 60 to 72 per cent. of metal, with a flux composed of about from 3 to 5 parts by weight of culm, and from about 1-16th to ¾ of a part by weight of wrought iron, wrought-iron borings or turnings, or tin-plate clippings, and from about 1-16th of a part to 2 parts by weight of caustic soda, bicarbonate of soda, pearl-ash, or potash. According to the nature of the tin ores, the exact proportions must be fixed by a competent smelter, whose experience will readily enable him to apportion the proper doses, according to the ores operated on. The patentee smelts the mixture of ore and flux in an ordinary smelting or reverberatory furnace, in like manner to that usually pursued for the purpose of reducing tin ores. The invention consists—3, of an apparatus for treating ores and other matters containing arsenic, in order to obtain arsenic therefrom. The apparatus for obtaining arsenic from ores, and other matters containing the same, consists of a furnace surrounded by flues, with an outlet leading from the furnace into a chamber for collecting the gases. The ores or matters are fed into the retort through doors made for the purpose, or through shoots leading into and through the roof or upper part of the retort; a pipe is carried through and into the upper part of the retort, through which the arsenious gases are led into the usual poison chambers or flues. *Patent completed.*

680. H. B. Barlow. *Certain improvements in looms for weaving.* Dated March 13, 1863.

The nature of this invention consists in supporting the bobbins containing the warp yarns or threads by a plate connected to or forming part of the loom, and in guiding the said warp threads direct to the loom, whereby facility is afforded in piecing up a broken end, and also in sizing and dressing the warp before it passes through the healds, and in an improved arrangement of parts for giving off or delivering the warps, and for taking up the woven fabric. *Patent completed.*

681. J. Harris, J. Butler, and J. H. Fraser. *Improvements in machinery for rolling armour plates, bridge plates, boat plates, and other plates and bars of iron.* Dated March 13, 1863.

These improvements consist in constructing and arranging rolls in the manner hereinafter explained, whereby lateral pressure is applied to plates and bars of iron during the rolling process, and the plates or bars are fed to or conducted from the rolls in a simple and expeditious manner. Plates and bars of iron rolled by this improved machinery are of uniform or nearly uniform density throughout. The patentees make the upper roll of the pair of rolls somewhat shorter than the lower roll, so that the lower roll projects at either end beyond the ends of the upper roll. A recess is made in each of the standards carrying the rolls, the said recesses being at about the level of the acting surfaces of the rolls. In each of the said recesses a rotating circular collar is placed, the said collars rotating on vertical axes. The lower face of each rotating collar rests on the cylindrical surface of the lower roll, and the cylindrical surfaces of the rotating collars bear against the ends of the upper roll. When a plate of iron is passed through the rolls, the edge of the plate is prevented from spreading laterally by the rotating collars; and the edges of the plate are subjected to the same pressure, or nearly the same pressure, as the other parts of the plate, and great uniformity and excellence of quality is obtained in the rolled plate. The upper roll can be raised or lowered without interfering with the rotating collars and lower roll. To roll plates or bars of any required width, it is only necessary to employ an upper roll having a length equal to the width of the plates to be rolled, the rotating collars being adjusted so as to bear against the ends of the upper roll. The lower roll being always longer than the upper roll, does not require to be changed on changing the upper roll. The rotating collars are adjusted by means of screws acting on their bearings in the recesses in the standards. They guide the plate or bar to and from the rolls by means of rotary guide rolls provided with flanges sliding thereon, so as to accommodate plates or bars of different widths. The invention is applicable to the rolling of armour plates, bridge plates, boat plates, and other plates and bars of iron. *Patent completed.*

682. C. T. and A. Lutwyche. *Improvements in metallic pens.* Dated March 13, 1863.

This invention consists in making metallic pens from the alloy called aluminium bronze, which alloy is composed of copper and aluminium in the proportion of about 92½ parts by weight of copper to about 7½ parts by weight of aluminium. Metallic pens may be manufactured from the said alloy by the machinery commonly employed for the manufacture of steel pens. Pens made of aluminium bronze may either have iridium osmium points, such as are ordinarily used for gold pens, or the points may be of the same material as the body of the pen. Pens made of aluminium bronze have the appearance of gold pens, and are not corroded by writing ink. *Patent completed.*

683. J. Taylor. *Improvements in fire bars and bearers.* Dated March 13, 1863.

These improvements in fire bars consist—1, in constructing fire bars with a number of taper holes or openings, which holes or openings are made horizontally through the strengthening rib or belly of the bar. By reason of the holes or openings being made taper, a much greater supply of atmospheric air is obtained, which assists the combustion of the gaseous products of the fuel. 2, In the top or surface of the bars is a wide groove running longitudinally the whole length thereof; these grooves becoming filled with the fine ashes protect the bars from the heat of the fire, and also prevent the adhesion of clinker, thus adding greatly to the durability of the said bars. 3, The inventor constructs fire bars with the taper holes or openings, as hereinbefore described; but instead of the longitudinal groove in the surface thereof, he constructs them with a number of projections cast across and on the surface of each bar, forming alternate projections and spaces. These spaces answer and are for a similar purpose to the longitudinal groove described in the bar above. The bearers or cross rails which support the fire bars are perforated with a number of taper holes or openings for facilitating the admission of atmospheric air to the bars and fire. *Patent abandoned.*

684. J. B. M. A. Bourreiff. *Improvements in transferring, by the means of typography, colours and metals on surfaces in general.* Dated March 13, 1863.

In performing this invention, the inventor takes paper, sized, unsized, or half-sized, and pays it over with one or more coats of such preparation as that next hereafter described, or its equivalent:—Gum arabic dissolved in water, tapioca, sago, starch, or other fecula mixed in hot water, or boiled in water, and the whole well mixed and stirred. The preparation may be varied so long as similar sticking, adhering, and agglutinant properties are preserved. After the coating it is better to "satin" the paper. The satining aids the transfer of the typographic impression to be made on the coating—the coating completely separates the design from the paper as hereafter stated. The typographic impression is taken in the ordinary manner, but in lieu of ordinary printing ink he uses a mordant or strong varnish, in which it is better, with the view of obtaining more intense colour, where colour enters into the design, to incorporate or mix a quantity of the desired colour with the mordant or varnish. The form or block is covered or "inked" by a roller with the mordant or varnish, and a print, on the coated paper, is taken directly after the printing; or before the ink becomes dry, he powders it over with the same colour as that in the mordant by means of a puff, soft brush, hare's foot, or other like article. This operation should be performed at every change of colour. When all the colouring matter for the print is dry, he cleanses it by a feather, brush, or other like soft article drawn over it. When the paper has received all the colours, and the gold entering into the design, it is as well—though not absolutely necessary—to pass the paper through rolls, to give a glaze, and to impart homogeneity to the colours and the gold. To transfer the impression to the surface for receiving it, he applies an hour or more before using the impression, both to it and to the surface to which it is to be transferred, a liquid, composed of essence of turpentine, Venetian turpentine and colophony, in the proportion of 5 parts of turpentine, 1 part of Venetian turpentine, and ½ part of colophony. He then applies the print to the surface, and uses a roller or rubs with the palm of the hand or otherwise to ensure contact of every part of the impression. He afterwards wets or moistens the paper and separates or draws off the paper from the impression, when the design alone will adhere to the surface to which it has been transferred. For articles subjected to firing after the transfer of the design to them, the colours used must be mineral, and not vegetable, and should be such as are employed by painters on porcelain, china, and glass. Instead of paper for carrying the design, he sometimes uses a textile fabric. *Patent completed.*

685. W. H. STUBBE. *Improvements in governors for marine and other engines.* Dated March 13, 1863.

This invention consists in a peculiar construction of hanging shaft carrying the governor balls, and driven from above, and also in fitting such hanging governor in gimbals, or a universal joint, so that it may always hang vertical, notwithstanding the motion of the ship or vessel, the gearing that rotates the governor always remaining properly in contact, and hence the governor is rendered as efficient in regulating the speed of a marine engine as of a stationary engine. *Patent abandoned.*

686. A. WYDLER and C. THORNTON. *Improvements in printing and dyeing woollen fabrics.* Dated March 13, 1863.

This invention consists—1, in the use of a new substance as applied to the printing of woollen fabrics. For this purpose the inventors use the substance known as deoxidized indigo, in combination with gum or other thickening matter. 2, In producing colours upon woollen goods, the patentees, in the first place, print them with the said deoxidized indigo, or other printing material, and then dye them to any desired colour. *Patent abandoned.*

687. J. H. JOHNSON. *Improvements in fastenings suitable for portions of harness and other purposes.* (A communication.) Dated March 13, 1863.

This improved fastening is constructed as follows:—As applied to the hames of a horse collar, one of the branches is provided with two holes made at right angles to each other, and formed one above the other, so that the two will partially intersect each other. Into the lower hole is fitted a bolt or pin, having a transverse notch cut in it at the part where it crosses the upper hole. This bolt or pin is connected with a ring or metal eye through which the martingale is passed, the connection with the bolt or pin being such as will cause the bolt or pin to turn partially round its socket or hole on turning the ring or metal eye to one side. On the opposite arm of the hame there is formed a spindle or stud which fits accurately the upper hole above referred to, and a transverse notch is also formed in the under side of this stud corresponding to the before mentioned notch in the bolt or pin. In order to unite or secure the hames, the bolt or pin must be first twined partially round, so as to bring its notch in a line with the upper hole, when the stud can be readily inserted. The bolt or pin is now returned to its original position by bringing the ring or metal eye down again into a vertical position, whereupon the said portion of the bolt or pin will enter the notch in the stud or spindle, and lock it effectually in its place. The pressure of the martingale in the ring or metal eye prevents it from being turned sufficiently to release the hames, consequently the accidental opening of the hames is avoided. In order to release them from the collar, the martingale must be first disconnected, when the ring is free to turn the required extent for the opening of the fastening. *Patent completed.*

688. W. SMITH. *Improvements in machinery for cultivating land and setting seed.* Dated March 13, 1863.

For the purposes of this invention, the framing of the fore carriage is, by preference, of a triangular form, and is connected at its hinder end with an axle on which there are two wheels, which the patentee calls the main wheels, one at each end of such axle. There is also, at the front end of the fore carriage, a locking axle with two wheels, which have, in addition to their broad tyres, central projecting rims, which cut into the band when the machine is in use. The steering is by means of a lever handle on an upright shaft, by which the fore wheels and their axle are moved. At the front end of the triangular or fore frame is applied a draft instrument or apparatus, such as was described in the specification of a former patent granted to the present patentee, dated 11th January, 1856 (No. 87), in order that the end of the draft rope, which comes into action at a headland, may cause the implement to be turned by the power employed for drawing it from headland to headland. The cultivating tines, pressers, and seed tubes are arranged in a similar manner to that described in the specification of a previous patent granted to the present patentee, and dated the 13th May, 1861 (No. 1219). These tines, pressers, and seed tubes are mounted in a lever frame, the forward end of which is pin jointed to projections fixed on the axle of the main wheels of the implement. The front or triangular frame is connected to the axle of the main wheels, and the two outer parts or sides of the fore framing extend back, and have handles applied thereto, by which the fore wheels and front end of the fore carriage can be lifted. In front of the axis of the main wheels a seed box or chest is placed on the fore framing or implement, which, by trunks or passages, is connected to a smaller seed box placed on the outer parts of the fore framing, which are extended back, and which are bent upwards in order to carry such hinder seed box. On the axle of the main wheels is fixed a chain wheel, and on the shaft or axle of the hinder seed box is also fixed a chain wheel. Thus the chain wheel on the main axle, by an endless chain, gives motion to the axle in the hinder seed box. From the shaft or axle of the hinder seed box motion is communicated when desired to an axle or shaft, which, by drums or pulleys, gives motion to endless bands in the trunks or passages, by which the seed is raised from one seed box or chest to the other, as is well understood. From the under part of the hinder seed box pipes or flexible tubes descend to the drills, as is usual. The lever frame which carries the tines and drills is capable of being raised, and the raising may be done by any convenient apparatus. That which is preferred is a barrel put in motion by a crank handle and bevel gearing, mounted on the end of the bars which support the hinder seed box. The hinder lever frame which carries the tines has two wheels, which run on the land and regulate the depth to which the tines descend into the land, and provision is made for adjusting the tines in the lever frame or for adjusting the axles of the wheels. *Patent completed.*

689. W. E. GEDGE. *An improved plough.* (A communication.) Dated March 14, 1863.

This plough is composed of a beam or body similar, by its share, coulter, mould-board, handle, and oblique axle, to the ploughs usually used in vineyards, but differing from them in the tie piece, and a vertical shaft turning in sockets, one of which is on the heel. The upper part of this shaft receives the moveable handle, and the shaft further carries the small plough beam, which is composed of a concave mould-board, a coulter, and a share. If the ploughman acts upon the moveable handle, the small plough beam will describe a greater or lesser angle; and if, on the contrary, he brings it against the fixed handle, the small beam will come into line, and be lodged between the mould-board of the main beam and its fore part. The obliquity of this movement is regulated by a double segment of a circle placed on the tie piece and pierced with holes, into which passes an iron pin for arresting the moveable handle. This plough, by means of a moveable frame fitting on the axle, lends itself to every description of ploughing, in lines or furrows, whether one horse be on the left of a row of vines or other plants, and the other horse on the right, or whether both be on the same side. And this plough, by changing the form of the instruments, will work between two rows of all plants cultivated in ridges or lines. *Patent abandoned.*

690. F. RUDRUM. *An improved apparatus for registering.* Dated March 14, 1863.

This apparatus consists of a box or case, one side of which the inventor terms the cashier's side, and the other the indicator side or front; the said box or case contains the registering mechanism, which will be covered up, but on the cashier's side there will be glass, through which the indicating or registering figures will be visible. The mechanism consists of spring stops and stop pieces, or mechanism acting on shafts or axles with wheels set thereon, and for use in establishments having a number of assistants, requiring to register receipts of cash. The apparatus will be divided so that some wheels and mechanism will be appropriated to indicating each of the assistants whose receipts are to be registered, others the amount of cash received form each such assistants, and others the total amounts received from all the assistants up to a given amount. *Patent abandoned.*

691. W. WEST. *Improvements in valves.* Dated March 14, 1863.

The chief advantages obtained by these improvements in valves are facility in adaptation to degrees of pressure, facility of renewal, simplicity of construction and form, easy and equal action, easy adaptability to any position, and cheapness, as a result of simplicity. The principal features of the new valve are a valve seating, which would commonly present a form simply conical, and an india rubber or other elastic band or cord, which the patentee proposes to coil spirally about the external surface of the said seating within a groove formed for its reception. The bottom of this groove is perforated more or less frequently and extensively for the emission of water, steam, fluids, air, or gases. *Patent completed.*

692. J. PAGE. *Improvements in taps or valves.* Dated March 14, 1863.

This invention is not described apart from the drawings. *Patent completed.*

693. J. W. M. CARTER. *Improvements in machinery for sawing or cutting wood.* Dated March 14, 1863.

This invention is not described apart from the drawings. *Patent completed.*

694. W. TANGYE. *Improvements in portable hydraulic punching machines.* Dated March 14, 1863.

This invention is carried out as follows:—The cylinder in which the cam works is situated vertically, and is open at the bottom. The cylinder is connected with the rest or support which carries the fixed punching tool, by means of a strong bracket of a nearly semicircular form. The upper or moveable punching tool is fixed to the bottom of the ram, and projects from the open bottom of the cylinder. The pump is situated vertically or horizontally at the top of the cylinder, and is fixed in the reservoir containing the water or other liquid with which the machine is worked. The said reservoir is supported at the upper part of the cylinder. The descent of the ram and moveable punching tool is effected by working the handle of the pump. The ascent is effected in the following manner:—The pump is so constructed that, by moving its handle beyond the point to which it is required to be moved in working the pump, the valves of the pump are opened and the liquid may pass from the cylinder through the pump to the reservoir. In order to lift the ram, a lever is made to turn on an axis on the side of the cylinder. A cam on the said axis engages in a recess in the side or the ram, or with a shoulder on the said ram, and by depressing the lever the said cam raises the ram. The form of the cam is such that it does not impede the descent of the ram. *Patent completed.*

695. R. ALEXANDER. *Improvements in mariners' compasses, and the parts in connection therewith, and in the application thereof to magnetic instruments.* Dated March 14, 1863.

This invention consists in compensating or adjusting media, or both in combination, to render the magnetic needle independent of the local attraction of iron or other metals, metallic ores, or compounds, in the ship, vessel, or other place where the compass or needle is fixed or used. The means by which the patentee proposes to effect the said improvements, are:—1, By appliances of counter-acting and adjusting magnets or magnetic poles upon the compass needle card or cards, or otherwise placed, as may be found most effective in practice; 2, by the use, if necessary, of a moveable magnetic ring or rings, attached to the needle card by springs or otherwise, so as to be easily removed when it is required; 3, by the use of a series or number of magnets placed on or in a flat or curved surface, with or without rims or bands of soft iron, stationary or revolving, above, below, or horizontal with the middle card or cards, or both above and below them; 4, by the application of electricity or galvanism in conjunction with a part or the whole of the aforesaid appliances; 5, by the use of one or more of the magnetic needle cards, and one or more of the appliances of those explained above, placed one above the other, revolving in union or independent of one another on the same (or one distinct) pivots, or one or more of them stationary and another or others revolving, or any one or more of these used in conjunction with a simple magnetic compass card, as commonly used, only revolving in distinct pivots whilst a part may be stationary; 6, by the use of aluminium metal for the needle cards, or india rubber composition commonly called ebonite for the cards, rims, bowls, hoods, boxes, binnacles, and gimbals, and other parts of the compasses and appliances, or an admixture of steel filings or cuttings in the india rubber composition for some of these, or the whole of the said parts above referred to; 7, by the use of hollow iron spheres or spheroids to encompass a part or the whole of the apparatus; 8, by the application of a spring pivot or point on which the magnetic compass card revolves, and springs to an outward or second gimbal to the bowl; 9, by the application of the said invention to electro-magnetic instruments. *Patent completed.*

696. J. C. RICHARDSON. *Improvements in the construction of ships.* Dated March 14, 1863.

It is, according to this invention, proposed to construct the frames or ribs of double-angle or T-iron, having the flanges on the outside, with holes punched for the reception of fastenings. Such iron frames may be galvanized or coated with paint, or other material, or otherwise protected from oxidation or not, as required. The space between these frames is filled in with short lengths of wood plank, the same thickness as the moulded size of the iron frames, and dressed fair with the iron outside and in, or made thicker so as to project inwards beyond the inner edge of the iron frames, and to butt against each other, and secured by means of iron or other rivets to the flanges of the iron frames, or in any other manner. If in the construction of the ship wood be partially used for floors or transoms, or fashion or other timbers instead of T or angle iron, or in combination with it, so as to render the filling-in pieces of wood partly unnecessary, then such filling-in pieces to be only partly used. The keel, stern, and stern-post are to be of wood. The outer planking, which is to be of wood, is secured by wooden trenails or metal bolts, or other suitable fastenings, which may be rivetted or otherwise secured on the inner work. An inner planking may be added of wood, and all or part of the fastenings may be driven through it from the outer planking. *Patent abandoned.*

697. W. YOUNG. *Improvements in type composing and distributing machines.* Dated March 14, 1863.

We cannot here give space to the details of this invention. *Patent completed.*

698. R. MORELAND, jun. *Improvements in apparatus for making extracts of hops and for selecting or separating the seeds and pollen from hops.* Dated March 14, 1863.

We cannot here give space to the details of this invention. *Patent abandoned.*

699. J. WALWORTH. *Improvements in machinery or apparatus for washing or cleansing and drying Egyptian wheat, beans, and other kinds of grains or seeds.* Dated March 14, 1863.

The first part of this invention consists of a cylindrical vessel, having a central rotary spindle therein, on which are a series of projecting arms. This cylinder and spindle are by preference placed vertically. There is also another cylinder, with a central rotary spindle, having an archimedian screw thereon, which cylinder is, by preference, placed at an inclination to the former cylinder, and a channel or recess is formed longitudinally on the upper side of this inclined cylinder. The two cylinders are connected

by a spout or pipe at their bottom ends. A hopper is placed above the vertical cylinder, from which the grain to be washed is supplied or fed thereto, and an outlet spout is provided at the top end of the inclined cylinder for the grain to pass out. Also a pipe and tap are introduced at the top of the cylinder for the supply of water. Both cylinders are kept full and overflowing at or near the top of the vertical one, and an outlet pipe and tap are provided at the bottom for the escape of water and dirt. Motion is given to both the spindles by suitable gearing or pulleys, and straps or cords, so as to produce agitation of the grain in the vertical cylinder, and cause the archimedian screw to raise the grain up the inclined cylinder, from which it escapes at the top by the spout. An outlet is also provided at the top of the vertical cylinder for chaff or light dirt to float off, and there is also a perforated false bottom placed in the inclined cylinder to prevent the grain from passing out by the dirt pipe. The second part of this invention consists of a vertical hollow spindle capable of rotating, having a series of hollow circular tables attached thereto, and communicating therewith. A series of scrapers are placed in contact with the upper surface of each table, at tangents thereto. Steam is supplied to the hollow spindle at the top, and condensed water is let out at the bottom. Grain, after being washed, as set forth in the first part, is conducted by a hopper or dish to the centre of the uppermost table, and is gradually pushed outward by the scrapers off the edge as the spindle and table rotate, whence it falls into another dish or upper table, which conducts it to the centre of the second table, where it is again driven gradually outward by the scrapers to and off the edge to the next table, and so on from one table to another, when it finally passes out at the bottom, dried. *Patent completed.*

700. W. Boaler. *Improvements in the preparation of colouring matters for dyeing and printing.* (A communication.) Dated March 14, 1863.

This invention consists in the use of gases, such as those arising from the decomposition of metals or other substances by means of acids. The gases so produced are employed for acting upon aniline and its homologues, in order to produce oxidation, or partial oxidation, for the purpose of producing from aniline colouring matters which may be used for industrial purposes. *Patent abandoned.*

701. E. Oliver and G. Myers. *Improvements in apparatus for lowering and disengaging boats from vessels.* Dated March 16, 1863.

This invention consists of an apparatus by which a boat can be lowered into the water upon an even keel, and both ends simultaneously freed from the tackle, and is as follows:—Over the boat is a tube having a rod or bar in the inside furnished with a right-handed screw at one end, and a left-handed screw at the other. Over the screwed portions nuts are made to travel as hereafter explained. The tube is fitted at each end with a pulley block and a weighted hook; to the weighted hook the boat is suspended, the points of the hooks being held by the nuts to prevent the boat leaving them until disengaged. The ropes pass round the pulley blocks on the ends of the davits, and from thence to barrels fitted to suitable framing firmly bolted to the deck of the ship. The barrels are geared, and their rotation is governed by means of a break under the control of a man in the boat. The rod or bar has at one end a small hand-wheel, by which it is turned. *Patent abandoned.*

702. F. Hayes. *An improved stove or fire-grate, for heating, cooking, boiling, or other similar purposes.* Dated March 16, 1863.

This invention is not described apart from the drawings. *Patent completed.*

703. T. W. Willett. *Improvements in means for reefing and furling square sails of ships and vessels from the deck thereof.* Dated March 16, 1863.

The sail is, according to this invention, bent to a wooden roller, secured on the fore part of the yard by suitable bearings at each end, and supported in the centre by a roller claw firmly secured to the mast, and of sufficient size to receive the entire sail when wound up on the roller spar. A solid or hollow metal rod of equal length to the roller spar is secured by turns in suitable bearings fixed near the ends of the yard, and forming part of or closely connected with those in which the roller spar turns. Each end of the metal roller is furnished with a cog-wheel, which gears with a similar wheel on the ends of the roller spar. On the centre of the metal roller is a chain wheel, grooved similar to the chain wheel of a clock, for the purpose of forming a secure hold for a chain, which, after passing over it, is led through two sheaves fixed in the mast, one a short distance above the other, but both higher up in the mast than the yard would be if the sail was set. The chain is of sufficient length to permit of the furling and unfurling of the sail, and the two ends are attached to two haliards, by which the apparatus is worked from the deck. Thus, when the sail is set, by slackening away the upper haliards, the yard will descend from its own weight, and the metal rod will be put in motion by the slackening of the chain, and communicate its rotary motion to the roller spar by means of the cog-wheels, and so reef the sail to any size required; by tightening the upper haliards the sail is set. *Patent completed.*

704. W. Vernon. *A new or improved means or apparatus for communicating signals or intelligence to or from railway trains or other similar conveyances, whether they be stationary or in motion.* Dated March 16, 1863.

In carrying out this invention, the rails on the line of railway are secured to chairs which are spiked to sleepers, in which case the inventor screws or otherwise fastens to such sleepers a number of non-conductors of glass, earthenware, or other material, which form supports for, or to which is or are attached, a line or lines of conductors or conducting materials, composed of iron wires galvanized, or other metal wires or rods or bars of metal, or other conducting substance; such conducting lines extend the whole length of the railway, and they may be outside the rails of each line of railway, or between the lines of railway. He also provides telegraphic apparatus in connection with the conducting line to each station on the line of railway, and to each break van and engine, and to one or more carriages, or to either or any of them; and, in addition to the telegraphic apparatus furnished to, and in connection with, the train, he provides each carriage, van, or engine, or either or any of them, with a vertical or other rod or rods, passing through a non-conducting substance, each rod having at its lower end a truck or pulley somewhat broader than the conducting line. Above the truck is a spring, which presses down the truck on the conducting line, so that while the carriage is in motion, or as it remains stationary, it can receive a message or signal from the station it has left, or the one towards which it is proceeding, or the guard or other persons may send a message or signal to either of such stations, or may receive or send a message or signal from or to any signal-man having in his signal-box a telegraphic apparatus in connection with the conducting lines. And, in order to prevent the electric or other current from passing through or proceeding beyond the train, he provides one or more rods in connection with the apparatus in each carriage, such rod or rods being in connection with the axles of the wheels or other parts of the carriages to conduct the current to earth. The guard or other person may send forward or backwards the message he receives, or the answer thereto from his apparatus. *Patent abandoned.*

705. G. P. Beley. *Improvements in discharging projectiles below the water-line of navigable vessels and other structures.* Dated March 16, 1863.

This invention consists in constructing a porthole below the water-line of the ship, fort, or other vessel, and in causing a tube at the required time to project through the said port—the outer end of the tube being closed. Through this tube the projectile is discharged. The porthole is closed by a specially constructed cover after the discharge. *Patent abandoned.*

706. T. Powell. *An improved chopping-block for butchers* Dated March 16, 1863.

In one modification of this invention, the lower part or stem of the block is composed of a hollow cylinder or pedestal of cast-iron open-work, and having projections in the interior towards the top, so as to receive and support a slab of wood about six inches thick, more or less. Castors may be affixed to the lower part of the pedestal for convenience of removal. Although ordinary cast iron may be used for the stem or pedestal of these improved chopping-blocks, yet the patentee prefers the use of malleable cast iron, as more suitable and less liable to fracture from the blows of the chopper. The whole construction may be of a circular, oblong, rectangular, or other convenient shape, and forms a light ornamental chopping-block, much more convenient and economical than, and answering all the purposes of, the heavy unsightly solid wooden block now in use. *Patent completed.*

707. J. Smethurst. *Improvements in the construction of ships and vessels for the purpose of obtaining additional strength and motive power.* Dated March 16, 1863.

We cannot here quote the details of this invention. *Patent abandoned.*

708. W. E. Newton. *Improvements in the manufacture of iron and steel.* (A communication.) Dated March 16, 1863.

This invention relates to an improved manufacture of iron and steel, the essential characteristic feature of the process being the completion of the manufacture by the liquefaction of the metallic product, whether of iron or steel, or iron more or less steely. *Patent completed.*

709. W. G. Eavestaff. *Improvements in the construction of pianofortes.* Dated March 16, 1863.

This invention is not described apart from the drawings. *Patent completed.*

710. J. H. Brierley and B. Greenwood. *An "All England" cricketers' clasp.* Dated March 17, 1863.

Provisional protection has not been allowed for this invention.

711. J. H. Brierley and B. Greenwood. *An album belt.* Dated March 17, 1863.

Provisional protection has not been allowed for this invention.

712. W. H. Atkinson. *Improvements in studs or fastenings adapted to holding together parts of shirt fronts, wristbands, collars, gloves, and other articles of wearing apparel.* Dated March 17, 1863.

This invention consists of certain improvements in the construction of studs or fastenings, the object of which is that such studs or fastenings shall be adaptable to eyelet holes, instead of to the ordinary button holes, and also that the studs shall be applied and fastened to the garment without any derangement or creasing being caused thereto by the application of such stud or fastening. *Patent completed.*

713. W. E. Gedge. *Improvements in the modes or means for framing pictures, looking glasses, and other objects.* (A communication.) Dated March 17, 1863.

This invention is not described apart from the drawings. *Patent completed.*

714. W. H. Emett. *Improvements in processes for facilitating and combining the art of writing with engraving together on stone, applicable to maps, plans, specifications, and other lithography, which improvements are also available for transfers to zinc or stone, or printing from original.* Dated March 17, 1863.

In carrying out this invention, the lithographic stone is prepared by first graining, as for chalk drawing; the surface of the stone is then polished, after which the stone is burnished, taking care to keep the surface free from dust. The face of the stone is then covered over evenly with strong gum, allowing it to remain for some few hours, say from six to ten hours. When the tracing of the work to be drawn is completed, the gum is removed from the stone by washing almost the whole from the surface with a clean sponge. The stone should be now fitted in a lithographic press, and the surface damped with a little water, leaving no water on the stone more than necessary for securing a good copy of the tracing. The tracing is then placed on stone reversed, as is usual for a transfer in lithography, and pulled quickly through press; the impression will be found much firmer if pulled twice without lifting up the tympan, and the impression will then be transferred on to the stone, and quite fit for the engraving and ink work. The tracing must be made by using ivory black, mixed with a little water of about the consistency of lithographic ink, and a lithographic crow quill, or any pen that will produce a good firm line, should be used, as the firmness of the tracing ensures the better quality of work when transferred from tracing paper. In commencing the drawing and writing, the thick lines of the latter are to be executed first, then the thick or shadow lines of drawing. The work thus described must now be etched very slightly with a little weak diluted nitric acid and gum water, care being taken not to etch away the tracing that up to the present is not drawn. When the stone is quite dry, it should be slightly covered with a little red or black chalk, usually employed for showing the fine engraved lines on stone; the fine lines of writing and drawing can then be engraved with an ordinary stone engraver's point, or a diamond if necessary. When all the work is finished, the surface of the stone should be covered with a coat of sweet oil, which should remain on the stone from five to ten minutes, and then be removed with a clean sponge. The work is to be rolled-up distinctly by a good soft roller. Those generally used for printing stone engraving will be found suitable for the purposes of this invention. The work thus executed is fit for making re-transfers to stone, zinc, or otherwise printing from original. *Patent completed.*

715. John Cox. *Improvements in swimming baths and in apparatus for swimming, part of which apparatus is applicable to sailing or moving vessels in a circle.* Dated March 17, 1863.

The first part of this invention consists in introducing a false moveable bottom into swimming baths, such false bottom being formed, by preference, of a wooden frame to fit the bottom of the bath. The frame should be clad across or longitudinally with, by preference, spars of wood and bars of iron of sufficient strength, and about an inch apart, and in such proportions as to be of a specific gravity very little more than water, so that when immersed in water it may be very easily raised. The patentee introduces the false bottom into the deep end of the swimming bath, so that it shall occupy as much of the bottom as may be considered necessary. By means of pulley work or otherwise he is enabled easily to hoist the false bottom to the surface of the water, or as far as will enable swimmers to stand thereon, and thus prevent accidents from drowning. The raising one end only of the false bottom at the deeper end will in general be sufficient, the other end being allowed to be on the bottom of the bath where the water is sufficiently shallow. The second part of the invention relates to apparatus for enabling persons to swim or propel themselves in water, and has reference to former inventions for which letters patent were granted to the present patentee on the 19th January, 1841, No. 8802, and on the 14th July, 1857, No. 1974. Instead of the propelling part of the apparatus being fixed round the leg of the swimmer (as described in the specification of the said letters patent), he fixes it to what may be called the lower end of a stilt, the upper end of which is fastened to the leg by straps or other suitable fastenings, in a similar manner to ordinary walking or rope-dancing stilts. The lower part of the stilt may be cylindrical or polygonal (solid or hollow), but of such a diameter, say 3 to 6 inches, as will admit of at least six wooden ribs, about an inch in breadth, being hinged around it, each rib being from 4 to 8 inches in length, according to the extent of propelling surface required. These ribs have cloth or other flexible materials fixed to them on the principle of an umbrella, and are prevented from expanding beyond a limited space by check-strings. Instead of cloth being used, and forming an apparatus like an umbrella as just described, he sometimes hinges flaps of wood or other rigid material to a flat surface, which flaps expand and contract like the valves of a pump. In using the apparatus, the propelling part is below the foot, which rests on a projection from the upright of the stilt, immediately above the propelling part; and the under part of the stilt is so long as to enable a person to walk on land or in shallow water without injuring the propellers. He sometimes attaches these apparatus to guide rods, to be fixed to a floating frame, for the amusement of bathers. *Patent completed.*

716. W. E. Newton. *An improved preparation for the cure of scab, foot-rot, and other diseases of sheep and cattle.* (A communication). Dated March 17, 1863.

This invention relates to a compound of ingredients which will form a black soap soluble in water, and which, when dissolved and properly diluted, will be found an excellent specific for the cure of scab, foot-rot, and other cutaneous affections to which sheep and cattle are liable. To this end the inventor takes tar, pitch, resin, tallow, or spirits, oil, or fat, or tar, coal, or peat, or the oil or gum of the Australian grass tree, or obtained from the blue, red, and white gum trees of Australia, and any one or more of these are made soluble in or mixed with water, and subsequently added to a saponaceous mass made by mixing strong caustic lyes under pressure with waste animal matters. *Patent completed.*

717. G. De Laire. *Improvements in the manufacture of brown colouring matters.* (A communication). Dated March 17, 1863.

According to this invention, in order to produce a brown colouring matter, aniline, violet, or blue dye is taken, and treated with a salt of aniline. The salt which is found the most suitable is the hydrochlorate. *Patent completed.*

718. T. N. Miller. *Improvements in heating horticultural buildings.* Dated March 17, 1863.

This invention consists in combining two modes of heating heretofore practised—viz., flues on or near the floors of such buildings, through which the heated products from

the fires pass into the chimneys, and water troughs with perforated covers, similar to those heretofore used in combination with boilers, suitable for causing water to circulate in such troughs. *Patent abandoned.*

719. W. SYMINGTON. *Improvements in the process of and apparatus used in roasting and treating coffee and other organic substances.* Dated March 17, 1863.

The patentee claims the method of saving and utilizing the aroma, volatile oil, and other products evolved during the process of roasting coffee, cocoa, chicory, and other organic substances, by combining the cylinder or vessel in which they are roasted with one or more receivers or vessels containing cold roasted coffee, or nibbed or dried chicory, or other suitable substance, either powdered or otherwise, and in a desiccated or dried state, by which the aroma or volatile oil is absorbed and rendered valuable. *Patent completed.*

720. W. WILD and J. H. RANDEL. *A new and improved mode of inlaying gold and other metals in glass, and in a composition suitable for the manufacture of jewellery and other ornaments, buttons, and other similar articles.* Dated March 17, 1863.

In carrying out this invention, when the patentees desire to inlay gold or any other metal in glass, they place the metal to be so inlaid within a mould, which is then placed at one end of a pair of pinching pliers, and having melted sufficient glass to fill the mould, they compress the pliers, and the metal remains embedded within the glass, which is then annealed, and is afterwards ready for cutting and polishing. The glass most suitable for the purpose is the kind known as Bohemian glass, as this melts at a lower heat, and takes a better polish than any other description of glass; but when this is not to be obtained, or when they desire to produce a cheaper article, they use the common kind of English glass. When they desire to inlay gold or any other metal in the composition before mentioned, they first prepare the said composition by taking about four parts of glass and two parts of enamel, which, after being well pounded and mixed in a mortar, are placed in a copper mould, with the metal to be inlaid at the bottom of the mould. They then place the said mould on a copper plate (on which is spread a thin layer of plaster of Paris), and the plate with the mould on it is then placed in an enamelling stove, over a coke fire, until the whole is well fused: it is then annealed, and when taken out of the mould is ready for cutting and polishing. *Patent completed.*

721. W. DONVALAND and D. CRICHTON. *Improvements in looms for weaving.* Dated March 17, 1863.

This invention is not described apart from the drawings. *Patent completed.*

722. J. ROBERTS and R. NAYLOR. *Improvements in organs, harmoniums, and pianofortes.* Dated March 17, 1863.

In carrying out this invention, the inventors place the key-boards, keys, or manuals of organs, harmoniums, pianofortes, German pedals, and pedal claviers on springs at the front part, or they suspend the same from springs, so that when more pressure is used on the keys than is required for playing, the keys yield, and the swell shutters or venetians open open, thereby increasing and regulating the sound. Or, as a modification of the same principle, they place a spring of india rubber, or other suitable material, under each key, and thus obtain the same result. *Patent abandoned.*

723. R. A. BROOMAN. *Improvements in the manufacture of spoons and forks.* (A communication). Dated March 18, 1863.

This invention relates to the manufacture of spoons and forks from sheet metal, as hereafter described. The inventor uses an ordinary cutting-out or stamping press, on the bed of which he places matrices, and fits corresponding stamps or dies in the head; and he changes these matrices and stamps according to the progress of the work at the particular part of the work to be performed. He first takes a frame, and adjusts therein a matrix in one or more pieces, of the contour of the spoon or fork to be made. He places this in a counter-matrix, in which there is an inclined channel for receiving and leading away the piece of metal stamped from the sheet, as hereafter explained, and fixes the frame on the bed of the press. He fits a stamp or punch corresponding with the matrix in the head of the press. He places sheet metal on the matrix, and brings down the stamp or punch, when a blank, having the outline of a spoon or fork, is cut or stamped out, which, falling through the inclined channel, is removed for the second operation, which consists in turning up in a matrix and stamp for the purpose side pieces between the part for forming the bowl or prongs and the handle. The third operation consists in turning down and consolidating the side pieces so raised by another matrix and stamp; while the fourth operation consists in hollowing out the part intended for the bowl or for the prongs by means of a matrix and stamp constructed and shaped for such purpose. The fifth, and last operation, for giving the finished shape to the article, is performed in a matrix and stamp prepared for that purpose. *Patent completed.*

724. F. RICHMOND, H. CHANDLER, and J. G. RICHMOND. *Improvements in machinery for washing potatoes and other vegetables.* Dated March 18, 1863.

This invention consists in an improved mode of constructing the cylinders or drums in which potatoes or other vegetables are washed. The cylinder or drum is formed with a cast-iron or other frame, furnished with trunnions supported in bearings fixed to the ends of the trough containing water, as usual; one half of the cylinder or drum is loose, and it is provided with handles, by which it is easily removed from the frame in which it fits, and the other half is hinged to the frame, the two halves being connected together and to the frame by a spring catch or otherwise. The circumference and ends of the cylinder or drum (or the circumference only) are made with strips or bars of galvanized iron, or other suitable material. By this means the loose part of the cylinder or drum is easily taken out to remove the potatoes or other vegetables when washed, and to replace a fresh supply to be washed; and, in some cases, the machinery may be supplied with two loose portions, to save time in removing the washed and supplying the unwashed vegetables. *Patent completed.*

725. W. E. TAYLOR. *Certain improvements in machinery for reeling, winding, warping, and beaming yarn.* Dated March 18, 1863.

This invention consists in giving rotary motion by bands and pulleys to the spindles on which the cops or bobbins are placed, whereby any additional amount of twist can be given to the yarn in proportion to the speed at which the spindles are made to revolve. The inventor fixes the bobbins on stationary spindles, and draws the yarn through a guide placed in line with the axis of the bobbin. The flange over which the yarn is drawn is made of metal or other material having a polished surface to prevent friction; or a light flyer is mounted on the fixed spindles to guide the yarn, and by this means the tenderest yarn can be mounted without breaking; when the yarn is drawn off from the upper end of the bobbin, an additional twist for each layer on the bobbin is put in the yarn. When it is requisite to give a greater amount of additional twist to the yarn, he imparts rotary motion to the spindles and bobbins by means of bands and pulleys, the velocity imparted to the spindles depending upon the quantity of additional twist to be given. *Patent abandoned.*

726. H. KILSHAW. *Certain improvements in looms for weaving.* Dated March 18, 1863.

The object of this invention is to vary the motion of the lay, so as to obtain the requisite swell for the passage of the shuttle across the shed. In looms of the ordinary construction, the crank shaft is connected to the lay by means of rigid connecting arms or links. Now this invention consists in making the connecting links with a joint at or near the centre of their length. The end of the link jointed to the lay is provided with two stop pieces bearing alternately against the lay swords above and below the joint pin; the joint in the connecting links allows them to yield in turning over the back centre of the cranks, thus producing the required swell in the motion of the lay. The upper stop piece comes against a spring for assisting the connecting link back to the lower stop. *Patent abandoned.*

727. B. WREN. *Improvements in cleansing and treating certain descriptions of wheat and other grain.* Dated March 18, 1863.

We cannot here give space to the details of this invention. *Patent completed.*

728. E. LEGRIS. *A new or improved machine for thrashing out the seed of flax.* Dated March 18, 1863.

The object of this invention is to separate the seed from the stalk of flax in a similar manner to the present system of hand labour; and the machine by which the inventor effects this purpose is composed of a bench or frame, and an apron or feeding cloth to spread out or lay the flax to be thrashed, also of beaters or mallets, having blocks at the end, of about 20 in. long by 16 in. wide, which are made to fall upon the flax with a shock by means of a series of cams placed spirally on a shaft. Any motive power may be used; if steam or horse power, motion may be given to the driving shaft by means of fast and loose pulleys; if hand power be used, by a crank placed on the side of the shaft near the pulleys, or on the fly-wheel on the other side. A fly-wheel may be added to regulate the broken or checked motion of the cam shaft. The beaters, being raised by the action of the cams about 16 in. or 21 in. above the bench, and suddenly abandoned to themselves, fall with a certain shock, similar to the blow of the workman in hand thrashing. The flax spread on the feeding cloth may be easily turned during the working of the machine, and a perfect thrashing be effected. *Patent abandoned.*

729. T. OLDKNOW. *Improvements in the construction of jacquards employed in bobbin net or twist lace machines.* Dated March 18, 1863.

Under the centre of what is known as the Manchester top, the patentee places a threefold sley of wirework, consisting of horizontal bottom or horizontal or bottom sley, a front side or front sley, and a back side or back sley. The said front bottom and back sleys are formed of wires bent at right angles; the ends of the wires which form the front and back sleys are connected to other wires or plates at right angles to them, and are secured by twisting them with lighter or thinner wire, or by rivetting or soldering them together. The centre portion of the wires which form the horizontal sley are crossed at right angles by other wires. The horizontal or central sley is provided with as many strings or wires as there are holes in one side of either of the cylinders, when two cylinders are used, or with half as many strings or wires as there are holes in one side of the cylinder, when one cylinder only is used. In front of the central or horizontal sley are the strings or wires belonging to, or to which motion is communicated by, the front wires and the front cylinder when two cylinders are used; and at the back of the central or horizontal sley are the strings or wires belonging to, or to which motion is communicated by, the back wires and the back cylinder when two cylinders are used. Each of these wires or strings is provided with a dropper of the required size; these droppers are divided into three several sets in three distinct boxes; the strings or wires to the droppers in the front box are also attached to one end of a thin metal jack lying in the front and back sleys; such jack is also attached to the wire or strings of what may be denominated No. 1 droppers in the centre and back box, and so on with every other subsequent number, so that when a selection is made by the front cylinder on the front wire in the front box, a selection is also made of the droppers in the central box; hence, by the employment of six cams instead of four as heretofore, and by using three driving bars instead of two driving bars as heretofore, he is enabled to make a selection of the droppers in the front and centre box, or in the back and centre box, by which means he thus moves all the threads which are passed through the bars operated upon by the droppers to the right or left, either wholly or in part, or right and left (according as the cards are punched), during the time which is occupied by the carriages leaving such threads and returning to them, both in the front and back motions of the machine. *Patent completed.*

730. F. NORRINGTON. *Improvements in girths or bands and knee-caps for horses.* Dated March 18, 1863.

In constructing a saddle girth, the patentee forms it of a strip of vulcanized india-rubber, or of a strip of vulcanized india rubber combined with cotton or woollen fabrics, in the same way as india-rubber belting is now commonly made; and to each end of the strip is connected a buckle. This he does, by preference, by making the ends of the strip double, each end of the strip being for this purpose turned over before the strip is vulcanized; the end of the turned-over portion of the strip is caused in the vulcanizing process to join with the strip, but the whole of the turned-over portion is not allowed to do so: a hole is thus left between the strip and the turned-over end; through this hole the bar of a buckle is passed. The buckle at each end of the strip carries three, or it may be other number of, small buckles, which, when the girth is being girthed to the horse, are made to receive the saddle straps. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated July 10, 1863.

1725. T. Legg, Northampton-square, machinist, and R. Griffith, Exmouth-street, machinist. Improvements in the construction of sewing machines.

Dated July 28, 1863.

1869. R. Dawson, 16, Craven-street, Strand, gentleman. An improved method of annihilating or extinguishing fires.

Dated September 19, 1863.

2306. L. F. Chezand, 3, Rue des Capucins St. Jacques, and H. J. Christen, 6, Rue Neuve d'Orleans, Paris. Improvements in printing postage stamps, bankers' bills, shares, and other similar documents, and in machinery employed therein.

Dated September 22, 1863.

2334. G. M. de Bayelt, 16, Stamford-street, gentleman, and J. E. Pigoulête, 22, Pitt-street, Fitzroy-square, analytical chemist. An improved method of compounding by agglomeration artificial fuel.

Dated September 30, 1863.

2395. H. E. Skinner, Shadwell. A new kind of conical packing for taps.

Dated October 1, 1863.

2405. F. Reid, Liverpool, produce broker. Collecting and saving the spirit or alcohol generated by spontaneous fermentation in raw sugar, concrete, melado, and molasses, and thrown off during the process of boiling or refining.

2407. W. E. Newton, 66, Chancery-lane, civil engineer. Improved apparatus for cleaning rice and other grain. (A communication.)

2409. P. Leslie, M.D., M.R.C.S., Eastbourne, Sussex. Improvements in preserving the bottoms of ships or vessels and other surfaces from the prejudicial effects of marine animals and vegetables.

Dated October 2, 1863.

2413. J. E. F. Lüdeke, 2, Stonefield-street, Islington, and M. Fischer, 28, Rue Taitbout, Paris. Improvements in obtaining motive power.

2415. J. Tees, Glasgow, packing manufacturer. Improvements in packing for stuffing-boxes and pistons.

2417. W. E. Gedge, 11, Wellington-street, Strand. An improved penholder and feeder. (A communication.)

2419. W. A. Torrey, New York. Improvements in lubricating the axles of railway carriages. (A communication.)

2421. G. and W. T. Shepherd, Great Grimsby. Improvements in restoring the crystals of lump or refined sugar which has been divided by saws, and in apparatus employed for this purpose.

Dated October 3, 1863.

2423. J. Schofield and J. Kirk, Rashcliffe Iron Works, Huddersfield, millwrights and machine makers, and W. Spivey, mechanic. Improvements in looms for weaving.

2425. E. B. Wilson, 10, Strand, engineer. Improvements in the manufacture of iron and other metals, and in the apparatus employed therein, parts of which are applicable for other purposes where high temperatures are employed, and also for ventilation.

2427. E. Pratt, Nottingham, lace manufacturers. Improvements in finishing woollen fabrics made on twist lace machinery.

Dated October 5, 1863.

2429. W. Hochl, C. Brakell, and W. Günther, Oldham. Improvements in rotary engines worked by steam, water, or other motive power.

2431. J. M. and J. Stanley, Sheffield. Improvements in propelling.

2433. J. W. Guilmette, Manchester, manufacturing chemist. An improved substitute for whiting, pipe clay, and other analogous substances to be employed to produce a white coating or surface.

2435. G. H. Ellis, Wellington-road, Bromley. Improvements in, and application of, apparatus for aiding the combustion of fuel.

2437. T. Ivory, Edinburgh, advocate. Improvements in steam engines, and in furnaces and boilers for the same.

2439. R. Pepper, Sheffield, brewer's clerk. An improved machine for pressing or crushing spent hops.

Dated October 6, 1863.

2441. S. Mathews, Birmingham, gunmaker. Improvements in breech-loading firearms.

2445. W. Batchelour, Finsbury Pavement, doctor of medicine. An improved apparatus for moulding and modelling palates, teeth, and gums for dental purposes.

2447. A. Johnston, Comely Bank, near Edinburgh, gentleman. Improvements on railway carriages.

Dated October 7, 1863.

2451. J. Caddick, Birmingham, tool maker. Improvements in the manufacture of runners, runner notches, and top notches for umbrellas and parasols.

2453. C. P. Button, 27, Leadenhall-street, merchant. Improvements in lamps, especially applicable to hydro-carbons. (A communication.)

2455. C. P. Button, 27, Leadenhall-street, merchant. Improvements in harrows. (A communication.)

2457. A. Rigg, jun., Chester. Improvements in apparatus for propelling vessels.

2459. J. Gibson, Ryhope Colliery, Sunderland, engineer. Improvements in cast-iron pit-tubing.

2461. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the permanent way of railways. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated October 9, 1863.

2473. L. Lefebvre, 9, Cecil-street, Strand, physician. Improvements in vapour bath apparatus.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, October 20, 1863.

1412. N. Walton. Drying and airing clothes.
1433. R. A. Brooman. Distillation of bituminous substances. (A communication.)
1438. H. F. McKillop. Compositions for coating or covering ships' bottoms.
1442. W. Roberts. Steam boilers.
1444. J. Brooke. Miners' lamps.
1446. T. Evans and E. Hughes. Applying one or more colours of ink to type in letter press printing by hand.
1450. T. M. Harrison. Metallic casks.
1462. J. Johnson and W. Braithwaite. Reversing levers for locomotive engines and others.
1469. J. C. Wilson. Unhusking rice and other seeds.
1470. G. Bedson. Cupolas and blast furnaces.
1471. T. C. March. Ornamentation or decoration of articles of furniture.
1473. R. Hughes. Scraping and sweeping turnpike and other highways, &c.
1477. J. Jones. Gas regulators.
1482. R. Blackburn. Traction engines.
1483. T. A. Elliott. Construction of, and ballasting, ships and other vessels.
1486. M. B. Westhead. Adapting tapes, ribbons, &c., to surfaces from which they may be unwound or rewound.
1488. H. G. W. Wagstaff. Feeding steam boilers with water.
1489. S. Robson. Steering apparatus.
1490. J. Shand. Steam fire engines, and steam boilers for the same.
1492. J. Forrester. Bricks, quarries, slabs, tiles, earthenware pipes, &c.
1495. I. B. Harris. Flexible and other tubes.
1505. J. Lightfoot. Fixing mordants in the processes of dyeing and printing textile fabrics or yarns.
1506. J. G. Jennings and M. L. J. Lavater. Moulding and vulcanizing articles of india rubber.
1510. W. Neill. Steam engines.
1517. J. F. Spencer. Tube joints.
1519. F. de Wyldé. Preservation of lead surfaces. (A communication.)
1524. J. A. Sparling. Twisting and winding silk.
1527. D. Barker. Treatment and preservation of yeast.
1530. R. Jobson. Machinery for making moulds.
1536. H. A. Bonneville. Machinery for the manufacture of bolts and rivets. (A communication.)
1547. R. Brownlee. Sawing machinery.
1559. W. Clark. Treatment of broom for the manufacture of paper pulp. (A communication.)
1577. J. Ellison and A. Rogerson. Slubbing intermediate and roving frames in throstles and winding machines.
1593. S. Smith. Liquorice.
1604. H. G. Craig. Preparing iron and other metal plates for shipbuilding and other purposes.
1629. C. H. Gardner. Lithographic and zincographic presses.
1668. H. A. Bonneville. Telegraphic wires. (A communication.)
1704. J. Thomas. Treating ores and earths containing iron.
1733. E. D. Chattaway. Railway signals.
1752. H. A. Bonneville. Breech-loading firearms. (A communication.)
1776. C. G. Glemm. New employment of magnesia.
1808. W. Simpson and J. Hutton. Hollow cutting tools.
2039. H. A. Bonneville. Processes in spinning wool. (A communication.)
2057. W. Jackson. Sewing machines.
2080. R. Griffiths. Retorts or ovens.
2129. C. Harratt. Tilling land.
2173. C. Jackson. Bolts.
2179. H. A. Bonneville. Attaching horses to carriages. (A communication.)
2180. H. A. Bonneville. Machine for glossing and glazing all kinds of threads. (A communication.)
2192. J. Rowell. Construction of fences, gate-posts, &c.
2356. J. Webster. Utilizing the waste flux from galvanizing works.
2388. H. Haigh and R. Heaton. Dyeing cotton.
2473. L. Lefebvre. Vapour bath apparatus.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed October 16, 1863.

978. P. G. Rowell and H. Holt.
985. A. Ford and R. Rigg.
986. H. Rafter.
988. E. L. Simpson.
990. M. Runkel.
991. J. W. Nottingham.
992. H., E., S., and J. Yeadon.
996. W. Campion and G. Wilson.
997. W. Ryan and W. Daniel.
999. T. Settle.
1005. J. Lee and E. Dawson.
1012. T. Richardson and J. C. Stevenson.
1014. J. Cavanah.
1015. J. B. Daines.
1016. W. N. Wilson and J. G. Grey.
1023. J. Thompson.
1024. J. Thompson.
1028. C. Pooley.
1030. S. Harrison.

THE MECHANICS' MAGAZINE.

Contents of the Last Number:— PAGE

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 30, 1863.

BOILER EXPLOSIONS.

THERE is, perhaps, hardly a subject within the range of human knowledge, which has been invested with such mystery as boiler explosions. Almost every agency of nature, has been called in to account for those fearful catastrophes which have desolated happy homes, and but too often extended misery far and wide. Merely to attempt a recapitulations of the various theories advanced to account for the tremendous effects produced by the violent rupture of a steam generator, would fill pages; while an extensive library would scarce contain the reports of innumerable discussions and controversies, elicited by the promulgation of the different opinions held by the authors of these various theories. Able mathematicians; clever engineers, standing high in their profession; continental *savants;* American philosophers; have alike devoted their time and energies to the investigation of a question, apparently abstruse, yet of the utmost practical importance to those who employ steam power. We certainly regard is as remarkable in the extreme, that these men have, one and all, overlooked the fact that, in the operation of getting up steam to the working pressure required, an amount of power is stored up within every boiler, almost without exception, sufficient to account for the most disastrous explosions on record. The mathematical investigation of this truth, we may safely leave in the hands of such men as Airy and Rankine; but the MECHANICS' MAGAZINE is perused by thousands, who have neither the time nor the ability, to study and comprehend profound mathematical disquisitions. We, therefore, once more place our explanation of the matter before our readers, convinced as we are that the violence of a boiler explosion, is as much the result of simple laws of nature, as the succession of day and night, or the fall of a body under the influence of gravitation.

It is impossible to communicate heat to water without immediately developing power, which we may or may not subsequently render available by means of a cylinder and piston. Every pound of coal consumed in a steam-boiler furnace, represents a certain amount of force, either stored up for future use, or conveyed at once to the steam engine, and through its agency distributed in various ways. Explosions occur at various pressures; and the measure of their violence is, other things being equal, the quantity of coal required to raise the steam from zero to the pressure existing within the boiler at the moment of the explosion. This will, of course, vary with the pressure, the quantity of the water, the quality of the coal, and the construction of the boiler. But it may be in all cases approximately calculated from the quantity of fuel consumed per hour. For the sake of illustration, we will suppose the case of a boiler, of the simplest construction, of fifty effective horse-power, burning 300 lbs. of coal per hour. Such a boiler will probably require some sixty minutes to get up steam from cold water to a working pressure of 60 lbs. per square inch. The same quantity of fuel will be burned during this hour per square foot of grate, as though the engine were at work. Now, 50-horse power exerted for an hour, is equivalent to 1,650,000 lbs. raised a foot high per minute, or to 99,000,000 foot-pounds, if the whole exertion of force, instead of being extended over an hour, were concentrated in a single minute. Now, we have seen that power is continually—to make use of a metaphor—poured into the boiler for an entire hour, in the act of raising the steam. On starting the engine, the further accumulation of force within the boiler is arrested; but none of that already stored up is withdrawn until the pressure falls below 60 lbs. per inch. Were it possible to avail ourselves of all the energy retained in the boiler, it would suffice to raise 99,000,000 of pounds a foot high in one minute were the fire withdrawn. Owing to the imperfections of machinery, and other causes on which we need not dwell, this we cannot do. Still the power is there, and cannot disappear, unless the steam is withdrawn from the boiler or this last suffered to cool down. "Power may be wasted, but it is never lost." When a boiler explodes, it is probably torn into fragments in a minute fraction of a second, and the entire amount of force, due to the combustion of 300 lbs. of coal, is called into action and extorted in that space of time. Even though the catastrophe lasted one entire second, the heat stored up in the water would exert a force great enough to raise 99,000,000 lbs. a foot high!—that is, the entire work of fifty horses exerted for an hour, concentrated in one second. The only thing remarkable is, that explosions are not more destructive than they are.

We have given this calculation to our readers, as though the heat employed in raising the water from 60 deg. to 212 deg. should properly be included in the total, from which the amount of work done by an explosion may be deduced. This is a point, however, open to discussion; and as a quarter of an hour, would probably suffice to raise the steam to 60 lbs. in our supposed boiler, from water at 212 deg., we prefer to divide the number of foot-pounds given above by four, the result still giving an amount of power sufficient to produce the most destructive results by its sudden exertion. It is not necessary to call in exploding hydrogen, electricity, or any of the occult forces of nature to account for the ruin of buildings or the destruction of life and property.

Simple as all this is thus far, and easily as the *violence* of an explosion may be explained, we find the causes which lead to the first rupture of a boiler surrounded by much that is mysterious. The primary cause of an explosion is a rupture above the water-line, and we have already pointed out the sequence of events, in our number for Sept. 18th. Whether this rupture is the result of congenital weakness, or of corrosion, depends on particular circumstances not easily ascertained in most cases. The singular effects produced on the plates of a boiler by oxidation, trituration, vibration, &c., have received much attention, and an amount of research has been expended on this branch of the subject which will, we trust, soon divest it of the uncertainty which hangs around it at present.

In order to understand the *rationale* of a boiler explosion, it is only necessary to comprehend the following facts:—Every body of water is made up of an assemblage of spherical particular atoms, capable of free motion on each other. When heated, the atoms of water within a boiler are surrounded by, so to speak, an atmosphere of caloric, tending violently to repel each one from its fellows. This force is equilibriated by the pressure of the steam in the upper portion of the generator, resting on the surface of the liquid, and thereby forcing the constituent atoms into propinquity. The instant, however, that an opening is made above the water-line sufficiently large to remove the pressure instantaneously, the repulsive action of the heat comes into play, and the water is separated into its ultimate atoms with a force proportionate to the quantity of heat stored up; rending the boiler into fragments, and destroying everything in the immediate neighbourhood. It is a mistake to imagine that any true dynamic steam is produced during this stage of an explosion, or that the water is dispersed in masses. Every particle repels its fellows with equal force, and it is opposed to reason, to suppose that many of the atoms can remain in that close approximation, which enables them to constitute a liquid, while others are converted into true steam: such a result would only ensue, if the explosion were sufficiently tedious to permit the caloric to pass from one part of the mass of water to another. This supposition is inadmissible under the conditions, and disproved by experiment. The dispersion of the water is usually attributed to the agency of interstitial steam, but there is evidence to prove that we are more correct, in stating *that it is due to the direct action of interstitial caloric.* The error has arisen from performing experiments, and ascertaining the effects produced by the *gradual* reduction of pressure on the surface of heated water, by withdrawing steam through a safety valve or stop-cock, a process in no way analogous to that which takes place in an explosion. A familiar instance of the direct repulsive action of heat on water, is afforded by placing a drop on a smith's anvil, and striking it with a bar of red-hot iron; the water is dispersed with a loud report, but no steam is produced. Water absolutely free from air may be heated to between 270 deg. and 280 deg., usually separating into its ultimate atoms with explosive violence, but still without producing true steam. If we regard the matter from this point of view, we see how erroneous is the idea that water can explode *per se.* As well might we state that the plates forming a boiler exploded. The water is perfectly passive in the transaction. Its particles are separated in the first instance, and these, in their turn, separate the plates which contained them the moment before. One great fact may be adduced in support of our explanation of the phenomena. There are hundreds of instances on record in which every pound of the many tons of water which the boiler contained, vanished on explosion. Yet it is certain that this water could not possibly have been converted into steam. There are, it is true, instances where boilers have burst, yet remained nearly full of water; but none of these explosions have been absolutely instantaneous, or very violent in their effects. In such cases, the catastrophe may, perhaps, be correctly attributed to the rapid generation of steam on the sudden reduction of pressure.

Steam power can never be worked with safety until we have an organized system of inspection established throughout the length and breadth of the land. There is scarcely an explosion on record which cannot be traced to the imperfect original construction of the generator, or the deterioration of the plates. We have ere now alluded to this branch of the subject, and may return to it at another time.

V. P.

THE FRICTION DYNAMOMETER.

ENGINEERS have now employed the friction dynamometer for more than twenty years. Absurdly termed a *force resister* in the prize sheets of the Royal Agricultural Society, it has been used by that body, at their (now)

quadrennial trials, for nearly twenty years. The friction dynamometer is, in fact, the only instrument by which the dynamic effect of a powerful prime-mover can be ascertained with complete accuracy, and, to the extensive use of it by agricultural engineers, is undoubtedly due the comparatively high dynamic efficiency of the portable engine. The improvement of the steam engine itself may be said to advance in a parallel line with the improvement of the instruments by which an accurate knowledge of its internal working can be ascertained. Just as the engine indicator is termed the stethoscope of the steam engine, so may the friction dynamometer be termed its force-measurer—the indicator and the stethoscope both help us to get at a definite diagnosis of the inward valves and mechanism of the respective patients, while the friction dynamometer measures the exact strength of the "giant with one idea." Strange to say, we may look in vain, in any of the treatises on the steam engine, for an account of the friction dynamometer. It is scarcely alluded to in the well-known Treatise on the Steam Engine, by the Artisan Club. In the otherwise excellent article "Steam Engine," in the *Encyclopœdia Britannica*, it is dismissed in a couple of lines. The truth is, that the friction dynamometer is only used in England by agricultural engineers. This enterprising body of men—the most progressive section of that progressive race, the engineers of this country—are members of what is quite a new profession, and this professsion is as yet without a literature. Now, we strongly suspect—and what we saw and heard at Worcester confirms us in our suspicion—that a little information on the matter will be acceptable to many of our readers. Besides, as we lately gave the numerical results of the trials, and our opinion on their scientific and commercial results, it behoves us the more to fully explain the important and remarkably ingenious instrument by which the thermo-dynamic results of the engines were obtained. In fact, if we look back to all the engine trials conducted by the Society, we see that, *de facto*, it is the friction brake that has determined the awards.

The first form in which the friction dynamemeter was used at the trials of the Royal Agricultural Society was that known under the name of De Prony. It is generally believed that this eminent man—the favourite engineer of the first Napoleon, himself a civil engineer of no mean ability—was the original inventor of the use of a friction brake as a measurer of force. This is a mistake. White, in his well-known "Century of Inventions"—portions of which were published at the beginning of the century—fully describes and illustrates a friction brake as a measurer of power. In alluding to the figure, White says:—"A gripe or brake, such as millers use to stop their windmills with, is fixed under (the fulcrum of a lever); it surrounds the wheel, and is then fastened to the end of the lever. The brake is thus pressed with greater or less force against the wheel, as the weight is placed more or less distant from the fulcrum of the lever. By these means a resistance of an equable kind is produced, capable of being adapted to *any* power it may be wished to measure, which makes this dynamometer a real *tribometer* or measurer of friction."

Ever since the introduction of the steam engine, and the more general use of water power, the necessity has been greatly felt for possessing an instrument to measure the efficiency of a prime-mover. Such an instrument gives the only means of ending the disputes between the buyers and producers of steam engines—disputes that continually occur, especially in countries where fuel is dear. Several means were proposed, but they all failed. Until the introduction of the friction brake, the only way of ascertaining the power of an engine was to compare it with the performances of another doing a similar duty, and supposed to be of a similar power. It is true that the power of an engine might be ascertained by making it wind up a weight tied to a rope, from a deep pit or mine; but the objections to the general use of such a plan are self-evident. The indicator is also a means of approximately determining the power of a *loaded* steam engine; it does not, however, give any means of ascertaining the friction, which increases with the load. Besides, the collation of mere indicator diagrams, multiplied by the number of revolutions of the engine under trial, would cause endless disputes at such competitive tests as those of the Royal Agricultural Society.

At last, after several abortive attempts to use a friction-brake for this purpose, by M. Hachette in 1811, by M. Gingenobre in 1815 (during a lawsuit between an English engine maker and his French customer), M. De Prony, in 1821, practically applied, and mathematically explained, the friction dynamometer.

Louis XVIII. was desirous of having a report on the old and new engines of Chaillot. In order to measure their dynamic effect, M. De Prony made a similar instrument to that still in use by the Royal Agricultural Society about thirteen years ago. The main shaft of prime-mover was embraced by two pieces of wood, each block furnished with a semicircular neck, like the brass shafts of a bearing. The two pieces were screwed up on the shaft by means of a bolt on each side. Attached to the wooden clips, was a long lever, furnished with a weight. The weight suspended at the end of the lever—always tending to fall—was kept up by the friction of the shaft, revolving in contrary directions at the other end of the lever. The friction could be either increased or diminished by screwing up the bolts more or less tightly. The whole of the work of the engine is thus expended in overcoming the friction, and the engine can even be entirely stopped by increasing the pressure on the brake. The weight exactly counterbalances the power exerted by the engine in motion; and indeed the instrument may well be termed a *friction balance*. The friction on the axle is evidently in the same ratio to the weight on the end of the lever, as the distance of the point of application of the weight is to the radius of the axle. Thus, the friction on the axle, multiplied by the radius of the axle, is equal to the weight on the end of the lever multiplied by the distance of the point of application of the centre of gravity of the weight. The unknown quantity—the friction, namely, on the axle—is evidently obtained by first multiplying the weight on the end of the lever by the distance of the point of suspension at the centre of gravity of the weight, and then dividing this product by the radius of the axle. Knowing the friction on the surface of the bearing, we can then ascertain the number of revolutions of the bearing per second or per minute. If, after measuring the circumference of the bearing, we multiply this circumference by the number of revolutions it makes per minute, and by the friction (ascertained as above) exerted upon that surface by means of the weight on the end of the lever, we get a product giving us the dynamic effect of the engine per minute—the real horse-power. In this calculation, we have not taken into account the weight of the lever itself and the scale in which is placed the weight. The lever may be either counterbalanced, or its weight at its centre of gravity taken into the calculation.

The Royal Agricultural Society soon felt the usual difficulties attending the use of this particular form of the instrument. In the first place, its use was attended with a certain amount of danger, and some dexterity and experience were required from the operator at the brake-screws. A too great tightness at the bearing had a tendency to suddenly carry round the brake on the devoted head of the operator. Besides, the surfaces had to be continually lubricated with a stream of soap and water, which, however, did not always prevent the wooden collar from getting on fire through the friction. In any case, the continual vibrations of the weight caused by the unequal side-friction on the clips, evidently led to some inaccuracy; the leverage got less as the weight rose higher, and the truth of the deductions was evidently thus affected. Before the introduction of the present excellent brake by the Consulting Engineer of the Royal Agricultural Society, many attempts were made, by several eminent men, to improve the apparatus. Fourneyron, when ascertaining, in 1829, the power of his well-known turbine, adapted a solid segment of a circle to the end of the lever. The centre of the segment was the centre round which the weight had to oscillate, and the leverage of the instrument was thus unaffected by any slight vibrations. At about the same period, Dr. Alban—the prophet of high-pressure steam; the author of the well-known work on the high-pressure engine; the enthusiast, who, when doctor to a hospital, was turned away for converting the *lavement* syringes into small steam engines—also attempted to improve the friction balance. He regulated its vibrations by means of a Watt's centrifugal governor. The governor was connected to one of the brake screws, by means of gearing. An increased speed of the engine under trial influenced the governor, which then screwed up the screws tighter, and thus slackened the speed of the engine; a slower speed, of course, brought forth a contrary action. The most important improvement, however, on the old lever brake, was thas of M. T. Barrois in 1829. The brake was adjusted to work below the engine shaft, and at an angle of 45 deg.: any vibration was thus immediately checked by the increasing leverage. Our limits will not allow us to allude to all the variations of the old friction brake—all these variations, however, point to the great store set by scientific men on this important instrument.

The first step made by the Royal Agricultural Society towards the adoption of its present form of brake was about ten years ago. The Society adopted a plan proposed by a Mr. Balk, formerly, we believe, of Ransomes and Sims, Ipswich, and who received a silver medal for his plan. It will be found described in Specification No. 1452, A.D. 1854. The strap of the brake is "connected to the end of an unequally-armed lever, which causes any shifting of the strap to increase or decrease its pressure on the friction wheel." We believe that this brake was first used at the Lincoln Meeting; but it did not act satisfactorily, and its employment led to disputes amongst the eager competitors. At the succeeding trials, the Royal Society adopted its present well-known form of brake, the action of which really leaves nothing to be desired.

The simple means of carrying out the compensating principle—doing away with side-friction—is stated to have been originated by Mr. J. G. Appold, the same man who has given

his name to a form of the centrifugal pump. It is embodied in Specification No. 13,586, A.D. 1851, in an apparatus originally proposed "for regulating and ascertaining the labour performed by prisoners." Mr. Appold also specifies the placing of the weight in a vessel filled with water—the same plan adopted with the weights on the brakes of the Royal Agricultural Society. "The water greatly resists any sudden alteration of the position (of the weight), but it can move *slowly* with little resistance from the water." A counter, driven by an eccentric on the brake-shaft, gives the number of revolutions of the brake. The present strap, as is well known, is in two halves, connected to a link, fixed to the framing at the bottom end of this link. Each half, of course, pulls the link in an opposite direction. About the same time as the temporary adoption of Mr. Balk's brake, Messrs. Clayton and Shuttleworth, of Lincoln, proposed the present plan of making the bearing part of the strap of separate small wooden blocks—an arrangement already in use for the brakes of cranes, cornmills, and similar machinery.

Of course, the plan adopted by the Royal Agricultural Society for calculating the power given out at their brakes is on the same principle to the mode of calculation with De Prony's brake. There is, however, a slight practical difference. The friction brake used by the Society is not fixed directly to the engine shaft, as with De Prony's brake. For the sake of convenience, the motion from the engine is communicated from the engine pulley, by means of a strap, to another pulley keyed on the shaft, on which is also the brake pulley. The relative diameters of the pulleys have thus to be taken in the calculation. The entire friction brake is also on wheels, so that it can be easily adjusted to any position of the engine.

The engine being brought opposite the testing shed, its proprietor then declares its horse-power and the number of revolutions at which he wishes it to be worked. The circumference of the engine-pulley in feet is then ascertained, usually by means of a tape. The horse-power—the number of revolutions—the diameter of its pulley being thus obtained; the diameter in feet of the pulley on the dynamometer; the circumference in feet of the distance of the pointer carrying the weight (measured from the centre of the brake-wheel) being, of course, previously known—the weight that has to be put on the engine is then calculated. This is done by multiplying the declared number of horses' power by 33,000, and the product by the diameter (or circumference) of the pulley on the dynamometer. This product is then divided by the product of:—1stly, the circumference in feet corresponding to the distance of the pointer carrying the weight from the centre of brake-wheel; 2ndly, the diameter (or circumference) of the driving pulley of the engine; and 3rdly, the number of revolutions of the engine per minute. We will suppose an engine, declared to be of 8 horses' power nominal, and making 120 revolutions per minute—with a driving pulley 15 ft. in circumference. The brake pulleys of the dynamometers of the R. A. S., are 14 ft. in circumference, and the "brake path" is 17·33 ft. We thus have:—

$$\frac{8 \times 32{,}000 \times 14}{17{\cdot}33 \times 15 \times 120} = 118{\cdot}5;$$

= the weight applied to the brake.

Seven pounds of coal and 1 lb. of wood per horse-power are now carefully weighed and served out to the attendants. The fire-box is then fired, and the steam is got up to a pressure of 50 lbs. on the square inch. In order to *afterwards* ascertain the quantity of coal used in getting up steam, the coal remaining outside the fire-box is carefully weighed, and the amount consumed is taken into account at a later stage of the operations. When the steam is at the fixed pressure of 50 lbs. the regulator valve is opened, and the engine is set to run against the dynamometer. When the desired speed of 120 revolutions per minute can no longer be kept up, the engine is stopped, and the number of revolutions is noted off the counter.

Another portion of fuel is now served out, consisting of 14 lbs. of coal per horse-power. No wood was weighed out this year to relight the fire-box. As the last trials, at the Chester show, in 1858, the fire-boxes had to be swept out, and 1 lb. of wood per horse-power was allowed to the attendants for lighting the fire. When the steam is again at the required pressure of 50 lbs., the engine is again started against the brake. It is now the business of the engine-man to get as many revolutions as possible out of the engine. Every means are used to spur on the flagging energies of the steam horse. The fire is always so carefully burnt out that but a slight layer of ashes is to be seen on the grate when the engine is stopped. The coal is broken into pieces of the size of a hazel nut, and the firebars are thus obliged to be very close together. A drop of oil on the coal would affect the true results, or even a deficiency of quality in a single lump of the coal served out. When the engine can no longer keep up the speed desired—in our case 120 revolutions per minute—it is stopped, as before, and the number of revolutions recorded by the brake counter are noted down by the judges.

The duty of the engine, the *mechanical time*, the minutes of duty (convertible terms) are got by dividing the total number of revolutions recorded by the counter—at the end of whichever bout it is wished to calculate—by the number of revolutions of the brake per minute. In the instance we have shown, the speed of the brake is—

$$\frac{120 \times 15}{14} = 128{\cdot}5;—$$

120 being the declared number of revolutions of the brake per minute—15 the circumference in feet of the engine pulley—14 the circumference in feet of the brake pulley. Let us suppose that the number of revolutions recorded after the second is 15,710. Then

$$\frac{15{,}710}{128{\cdot}5} = 122{\cdot}25.$$

The mechanical time of the second experiment is thus 122·25 minutes. If we now reduce these minutes to hours and decimals, and divide the number into the 14 lbs. of coal weighed out per horse-power, we get the coals per horse-power per hour consumed by the engine. We should of course get very uncertain results if only the coal consumed during the second experiment were taken into account. "Racers," provided with fire-bricks in the fire-box—with additional water-spaces, or other means—would lay up such a store of heat as to distance their less complicated competitors. The fuel consumed in getting up the steam is, however, ascertained in the following way:—In the same ratio as the number of revolutions—numbered by the counter—at the end of the second experiment, bear to the amount of coal then consumed, so are the number of revolutions—at the cessation of the first experiment—to the quantity of coal not consumed by the engine. The amount thus ascertained is deducted from the quantity used in the fire-box during the first experiment. The difference gives the approximate amount of coal consumed in getting up steam.

In the late account, by our special correspondent, of the Worcester Show, a full description is given of the general arrangements adopted for testing the engines.

MINERAL LOCOMOTIVES.

THERE are probably at this moment some hundreds of miles of tramroad in Great Britain, worked solely by horses, on which suitable locomotive engines could be employed with the greatest advantage. It would be interesting to calculate the number of tons of coal and iron-stone, lead and copper ore, lime-stone and clay, which are transported over roads more or less resembling railways in their general characteristics, during a single year. The grand total must be something enormous; yet, except in a few isolated instances, steam power has nothing to do with the transfer of mineral wealth from the pit's mouth to the iron furnace, or the locality where the crude material undergoes those processes which render its constituents useful in the arts. Whether the gross weight is to be estimated by thousands or millions of tons, certain it is that large gangs of horses, almost invariably employed under the contract system, perform by far the larger portion of the labour involved; the payments for their services forming a very considerable item of mining expenses.

The tram roads or ways of the English mining districts are widely removed from all that constitutes a perfect road. Made up of rails of all sorts, and different sizes, spiked down to inferior sleepers, placed far apart, and bedded on what scarcely deserves the name of ballast, the permanent way is bad enough; while curves of fifty or a hundred yards' radius, are frequently combined with inclines of one in forty, and occasionally one in twenty, rendering that which is already bad very much worse. Districts where such lines are the rule, and anything better the exception, appear to be, at first sight, extremely unpromising fields for the introduction of locomotives to the exclusion of horses. The retention of animal labour, therefore, is certainly not wholly owing to prejudice. Even though it were, the feeling is strengthened by the difficulties to be encountered in the substitution of mechanism for the thews and sinews which can set the troubles of the road at defiance. Still what has been already done by many mining proprietors, can be done by others; and the advantage to be derived from the employment of steam power in regions where coals can be had almost for a few pence per ton, are so manifest, that a strong stimulus is held out to all interested. The engineer and ironmaster, the mechanist and the owner of mines, hold equal stakes in every enterprise which proposes that coal and iron shall do the work of flesh and bone; it is equally a pecuniary matter to both; and the one will be as much benefited by doing a good business in colliery locomotives, as the other by effecting an annual saving in the expenses of haulage.

The difficulties to be encountered in the designing and construction of mineral locomotives, are, after all, more ideal than actual. Although the tramway is very defective indeed as compared with our great railway lines, still, it is far superior to any of the highways, either here or in the colonies, on which traction engines convey very heavy loads with ease and certainty. Although the track on which the wheels of the engine run is uneven, it is, at all events, hard; and provided the weight on each is not too great for the capabilities of the rails, locomotion is materially facilitated, while

the machinery is spared many of the shocks and jars which it would encounter in traversing an ordinary turnpike road, however good. The colliery locomotive is, however, a very different affair, when properly designed, from either the traction engine or the gigantic machines which work our great lines of intercommunication. Partaking in a great degree of the qualities of both, properly, it should be a copy of neither; possessing only so much of the one as will suit it for proceeding over bad roads, and so much of the other as will adapt it to their specialities; particular regard being had to the question of adhesion and the distribution of weight, on which success depends almost absolutely.

The gauges of the mineral lines of Great Britain vary considerably, not only in different districts, but even on properties in the hands of the same owners. As a rule, they are very narrow, 2 ft. 9 in. being, perhaps, the average, although many lines are laid with only a 2 ft. 6 in. gauge, while others have a distance of 3 ft. or 3 ft. 8 in. between the rails. The wider roads are usually far better laid and kept than the narrow ones, though neither have much to boast of in this respect. The substitution of locomotives for horses, would tend materially to their improvement, as the feet of the latter cut up and poach the ballast, and splinter the sleepers, which absorb water and are destroyed very speedily, as well by the trampling of iron-shod hoofs, as by the effects of the weather and the passing loads. It is very difficult to secure an equal distribution of weight in engines of the ordinary locomotive type intended for such gauges as 2 ft. 6 in. and 3 ft. It is impossible to get the fire-boxes between the wheels in such cases, as the grates would be unavoidably reduced to a width of only 12 in. or 14 in. In consequence, the fire-boxes must overhang the hind pair of wheels, and their weight, coupled with that of the foot-plate and its appurtenances, is quite enough to overbalance the smoke-box end of the boiler. The hind wheels are thus overloaded, while the leading wheels may barely have weight enough on them to keep them to the rails. Yet, if we seek to make up the equipoise by extending the engine forward over the leading wheels, it at once becomes unwieldy and exposed to a violent pitching motion when travelling. The curves are in general so sharp that a greater distance than 5 ft. between the centres is inadmissible, and a length of 5 ft. or 6 ft. overhanging at each end neither adds to the good qualities of a locomotive, nor improves its appearance. All things considered, we are disposed to recommend the upright tubular boiler for all lines below 3 ft. gauge. A weight of 8 tons is sufficient for locomotives intended to work such lines, as heavier loads are more than the imperfect track can sustain. Of course, in exceptional cases, this rule may be departed from, although we doubt if much advantage will be gained by doing so, as trains loaded with more than 70 or 80 tons are seldom needed; and if more power is required, this may be better obtained by the use of two small engines than one large one. It is merely a question of the powers of endurance of the permanent way. With the upright boiler placed between the wheels, weight may be distributed with the greatest nicety; while the machinery being all outside the frames, can be attended to and repaired with the utmost facility. It is true that the centre of gravity will be raised by such an arrangement; but this is no real evil, as a speed of four or five miles an hour need seldom be exceeded; and no matter how rough the road, there is little danger to be apprehended of an overturn at such a velocity. The upright tubular boiler has received so much attention, and consequent improvement of late, and the conditions of successful construction are so well understood and so easily secured, that it now ranks very highly as a safe and economical generator for moderate powers. The gauge would have little influence on the diameter of such a boiler, suspended as it would be between the axles. The foot-plate at one end of the framing being counterbalanced by the water tank at the other, the cylinders would be affixed in a horizontal or slightly inclined position to the framing at the sides of the water tank, into which the waste steam might be wholly or partially turned from time to time as the state of the fire dictated.

For wider gauges than 3 ft., the use of the ordinary locomotive type of boiler is not only admissible but judicious. Lines laid to this width are usually much better than those which are narrower, and a heavier class of engine may occasionally be employed on them with advantage. A moderately roomy fire-box can easily be got between the wheels, by making up the deficiency in breadth by additional length. Some trouble often results with the hind springs in such cases, best overcome by using those of the volute, or elliptical construction. We need scarcely say that outside cylinders are indispensable; the valve chests being best placed above the cylinders, perhaps, and worked by a rocking shaft. Some difficulty is often experienced in affixing the cylinders to the frames, as it requires very careful fitting to make such a permanent job, that they cannot work loose. American builders almost invariably cast an "apron" on the cylinders of all their locomotives, which is bolted directly to the boiler; the steam and waste ports being formed in the body of the apron, in such a manner that suitable necks enter the smoke-box, through holes cut for the purpose, into which the steam and blast pipes are directly fixed. The cylinders, in this case, have no connection with the frames except through the guide rods and boiler. The arrangement is very simple, easily fitted up, and scarcely ever works loose; while the frames may be made much lighter, as they are spared the strain of the cylinder. By placing the valve-chests outside, much inconvenient crowding of the machinery may be avoided. Boilers, 2 ft. 9 in. or 3 ft. in diameter, placed low, on frames not more than 24 in. or 30 in. asunder, effectually prevent access to everything not outside the wheels from above, and render it necessary to provide a pit, over which the engines must be run, to oil or inspect the machinery. It is needless to point out the evils attending this system. They are sufficiently obvious.

The use of very high pressures in mineral locomotives is never to be recommended, as a rule, to which there are few exceptions. Economy of fuel is no object in most cases. Expansion is seldom resorted to, and, therefore, there is nothing to be gained from such pressures as 120 lbs. to the square inch. From 60 lbs. to 70 lbs. is ample, provided sufficient piston area is supplied; and it is far better practice to give an increased diameter of a couple of inches to the cylinder than to strain the boiler by heavy pressures. There is no reason that the ports or passages should be proportionately increased in size, as only the same weight of steam has to be worked through them, and the extra weight of cylinders is of advantage in increasing the adhesion of the leading wheels. The constant succession of shocks occasioned by a bad road strain the rivets which attach the boiler to the frame, causing leaks, which are not easily remedied when very high pressures are resorted to. Tubes leak from the same reason; and much difficulty is often experienced in keeping them tight. With moderate pressures, much of this is avoided, and the durability of the fire-box and boiler generally, is materially promoted—a matter of greater importance to proprietors than the saving of a few tons of coal per annum. In all situations where it is intended that the locomotive should do all, or nearly all, the hauling, it is extremely desirable that enough of power be provided to permit each of the engines to have at least one day in each week in the shed, in order that repairs may be effected, and the machinery cleaned and adjusted. A neglect of this precaution frequently entails serious losses, and, as an instance of false economy, is very much to be deprecated.

GUNS *versus* ARMOUR PLATES.*

MR. PARSONS, in this little book, places before the public plans for a novel method of constructing great guns on the built-up system. The Armstrong gun may be considered as the representative of all that class of ordnance which is composed of rings of wrought metal welded successively together. This principle of construction involves longitudinal weakness. It is true that the metal may not be actually torn asunder; but still, the surfaces of the chase are exposed to a strain which gradually deteriorates the iron of which the gun is composed, and leads to its ultimate destruction, in consequence of the inner tube having to sustain almost unaided the whole of the strain tending to elongate the gun. Mr. Parsons proposes to overcome the defects of the Armstrong system by forming guns of an internal tube of wrought iron or steel, constituting the bore of the piece.

"This tube is turned on the outside slightly conical, and has a screw thread of suitable form cut on a considerable portion of its length at the breech end, the remaining portion at the muzzle being left slightly conical in the opposite direction; upon the screwed portion of the tube, a series of tubes of wrought iron, steel, or homogeneous metal having a corresponding screw thread cut on their interior, are screwed so as to encase the inner tube, and upon the remaining portion at the muzzle end a tube of wrought iron, steel, or homogeneous metal is forced or shrunk, its outer end extending rather beyond and enclosing the end of the internal tube; if preferred, however, the whole of the interior tube may have a screw thread cut on its exterior, and the tube, instead of being simply shrunk or forced on, may be screwed on to it in the same manner as the rings or tubes on the breech end. A screw thread is then, in like manner, cut on the exterior of the first tubes or rings, and on a portion of the internal tube, and another series of the tubes or rings are screwed on, and this process is repeated until the requisite thickness is obtained. For muzzle-loading guns the breech is closed by a plug, screwed into the internal tube, which is further secured by a breech screw behind it, secured into one of the outer rings or tubes. Should the gun be intended for a breech-loader, such modifications as the description of breech-loading arrangement require would have to be made. The tubes are so put together that each successive layer of rings or tubes will be in a state of tension upon, and compress the layer which it encloses, and this may be effected either by making the outer rings or tubes the requisite amount smaller than the inner tube and rings upon which they are intended to be secured, and expanding the outer rings or tubes by heat, then screwing them on and allowing them to contract by cooling, or by properly adjusting their sizes, and then forcibly screwing the rings on to their intended position, and thus subject them to the desired initial strain. When the rings or tubes encasing the inner tube are in separate pieces, it is essential that the different layers or series of rings or tubes should break joint with one another, so that they may be united into one mass, and impart longitudin[al]

* "Guns *versus* Armour Plates; a Practical Treatise on Great Guns." By P. M. PARSONS, C.E., A.I.C.E. London: Mitchell, 1863.

strength to the inner tube forming the bore of the gun; for this reason, not less than two layers besides the inner tube forming the bore of the gun, should be employed; and if these united provide the requisite longitudinal strength, and greater transverse strength be required, an additional layer or layers outside these may be simply shrunk or forced on without screwing. The inner tube and the rings may be made by any of the well-known processes now in use; but I consider the Armstrong or coil system may be advantageously used in connection with this mode of construction, as it provides a sufficient amount of longitudinal strength even to allow for occasional faulty welds in the tubes.

"It will be seen, that in guns so constructed, the tubes or rings surrounding the inner tube impart longitudinal as well as transverse strength to it, so that the whole mass of metal of which the gun is built up, is made available to resist the longitudinal as well as the transverse strain."

Mr. Parsons also proposes to strengthen our existing cast-iron guns by removing some of the metal by boring, and replacing this by slightly-conical wrought-iron lining tubes, forced in by hydraulic pressure. Our author is careful to supply his readers with calculations lucidly arranged, and apparently correct, of the relative strength of cast-iron guns in the ordinary state, and strengthened according to his system. On the question of cost we cannot quite agree with him; but there is much that is interesting to be found in the twenty-four pages of which the pamphlet consists. Mr. Parsons' observations on rifling appear sound in their general character; and as the subject now attracts so much attention, we recommend them to the attention of our readers.

ON THE EXPANSIVE ENERGY OF HEATED WATER.*

By W. J. MACQUORN RANKINE.

As the question of the quantity of mechanical energy which a given weight of water, heated to a given temperature, is capable of exerting in the act of partially evaporating without receiving heat, until it falls to a given lower temperature, has been raised in connection with recent researches as to the bursting of steam boilers, I may point out, that the complete solution of that question for any given liquid, together with a numerical example in the case of water, is given under the head of "Proposition XVII." of a Paper on "Thermo-dynamics," which was communicated by me to the Royal Society in December, 1853, read in January, 1854, and published in the "Philosophical Transactions for 1854."

That solution is expressed by the following formula (page 161, Equation 65):—

Energy exerted by each pound of fluid

$$= K \left\{ t_1 - t_2 \left(1 + \text{hyp. log. } \frac{t_1}{t_2}\right) \right\}; \ \ldots\ldots \ (1.)$$

in which K denotes the dynamical value of the specific heat of the liquid, being the product of its specific heat expressed in the ordinary way by "Joule's Equivalent":—

t_1 and t_2 the initial and final absolute temperatures; the absolute zero being 274 deg. Cent. or 493·2 deg. Fahr. below the melting-point of ice.†

Another equation (Equation 63 of the Paper) gives the following value for the excess of the final volume to which the mixed liquid and vapour expand, above the original volume of the liquid:—

$$\frac{K \text{ hyp. log. } \frac{t_1}{t_2}}{\frac{dp_2}{dt_2}}; \ \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \ (2.)$$

in which $\frac{dp_2}{dt_2}$ denotes the rate at which the pressure, in lbs. on the square foot, varies with temperature, at the final temperature.

When applied to the water in a steam boiler, these equations take the following form:—

The value of K for liquid water is—

772 foot-pounds per degree of Fahr. in a pound of water, or

1389·6 foot-pounds per centigrade degree in a pound of water, or

423·55 kilogrammetres per centigrade degree in a kilogramme of water.

The final absolute temperature is 212 deg. Fahr. + 461·2 deg. = 673·2 deg. Fahr.

The corresponding value of $\frac{dp}{dt}$, for Fahrenheit's scale and British measures, is 42; and $772 \div 42 = 18{\cdot}38$.

Let T denote the initial temperature on Fahrenheit's ordinary scale; so that $t_2 = T + 461{\cdot}2$ deg.

Then—

Energy, in foot-pounds, exerted by each pound of water

$$= 772 \left\{ T - 212^\circ - 673{\cdot}2^\circ \text{ hyp. log.} \left(\frac{T + 461{\cdot}2^\circ}{673{\cdot}2^\circ}\right) \right\}; ^{*} (3.)$$

Final volume of expansion of mixed water and steam in cubic feet per pound

$$= 18{\cdot}38 \text{ hyp. log. } \left\{ \frac{T + 461{\cdot}2}{673{\cdot}2^\circ} \right\} \ \ldots\ldots\ldots\ldots \ (4.)$$

It is worthy of remark, that *the energy developed depends solely on the specific heat of the substance in the liquid state, and the initial and final temperatures*, and not on any other physical property of the substance.

The following table gives some results of the formulæ:—

The first column contains the temperature on the ordinary scale of Fahr., with intervals of 36 deg. Fahr. = 20 deg. Cent.

The second column contains the expansive energy of 1 lb. of water, in foot-pounds.

The third column contains the velocity, in feet per second, which that energy would impress on a projectile of the weight of the water itself; that is, 1 lb.

The fourth column, the final volume of expansion of the water and steam, in cubic feet per lb.

For convenience, a fifth column is added, containing the initial absolute or total pressures in lbs. on the square inch.

The last line of the table has reference to the case in which the water would be totally evaporated.

TABLE I.

Initial Temp. Fahr. deg.	Energy, foot-lbs.	Velocity, feet per second.	Final Expansion, cubic feet.	Initial absolute pressure. lb. per sq. in.
212 ...	0 ...	0 ...	0 ...	14·70
248 ...	726 ...	214 ...	0·95 ...	28·83
284 ...	2,779 ...	428 ...	1·87 ...	52·52
320 ...	6,052 ...	624 ...	2·73 ...	89·86
356 ...	10,422 ...	819 ..	3·56 ...	145·8
392 ...	15,826 ...	1,010 ...	4·36 ...	225·9
428 ...	22,156 ...	1,194 ...	5·11 ...	336·3
...	...	...	...	...
about 2,360 ...	about 912,500 ...	about 7,666 ...	26·36 ...	unknown

In the absence of logarithmic tables, the following approximate formulæ may be used for temperatures not exceeding 428 deg.

$$\text{Energy, nearly} = \frac{772\,(T - 212^\circ)^2}{T + 1{,}134{\cdot}4^\circ}; \ \ldots\ldots\ldots\ldots \ (5.)$$

$$\text{Expansion, nearly} = \frac{36{\cdot}76\,(T - 212^\circ)}{T + 1{,}134{\cdot}4^\circ} \ \ldots\ldots\ldots \ (6.)$$

Glasgow, October 5, 1863.

Note added October 19, 1863:—

In explanation of the formulæ and tables it may be added, that the mechanical energy in column 2 is the equivalent of the heat which disappears during the process, being the difference between the whole heat expended and the latent heat of that portion of the water which at the end of the process is in the condition of steam at atmospheric pressure.

For the information of those who consider that the liquid portion of the water, owing to its small compressibility, acts like a volley of hard projectiles, a table is added, showing, for each of the initial temperatures in the previous table, what fraction of a pound of water continues in the liquid state, and how much of the energy developed is possessed by that liquid water.

TABLE II.

Initial Temperature Fahr. deg.	Proportion of the water which remains liquid. lbs.	Energy possessed by that liquid water. foot-lbs.
212	1·000	0
248	0·964	700
284	0·931	2,587
320	0·897	5,429
356	0·865	9,015
392	0·835	13,215
428	0·806	17,858
...	...	...
about 2,360	0	0

In the formulæ and tables, it has not been considered necessary to take into account the small increase which the specific heat of water undergoes as the temperature rises.

W. J. M. R.

* Read at the Institution of Engineers in Scotland.

† In the original Paper, the absolute zero of heat was assumed to be 272½ deg. Cent. below the melting-point of ice. The value now adopted, 274 deg. Cent., is deduced from later experimental data.

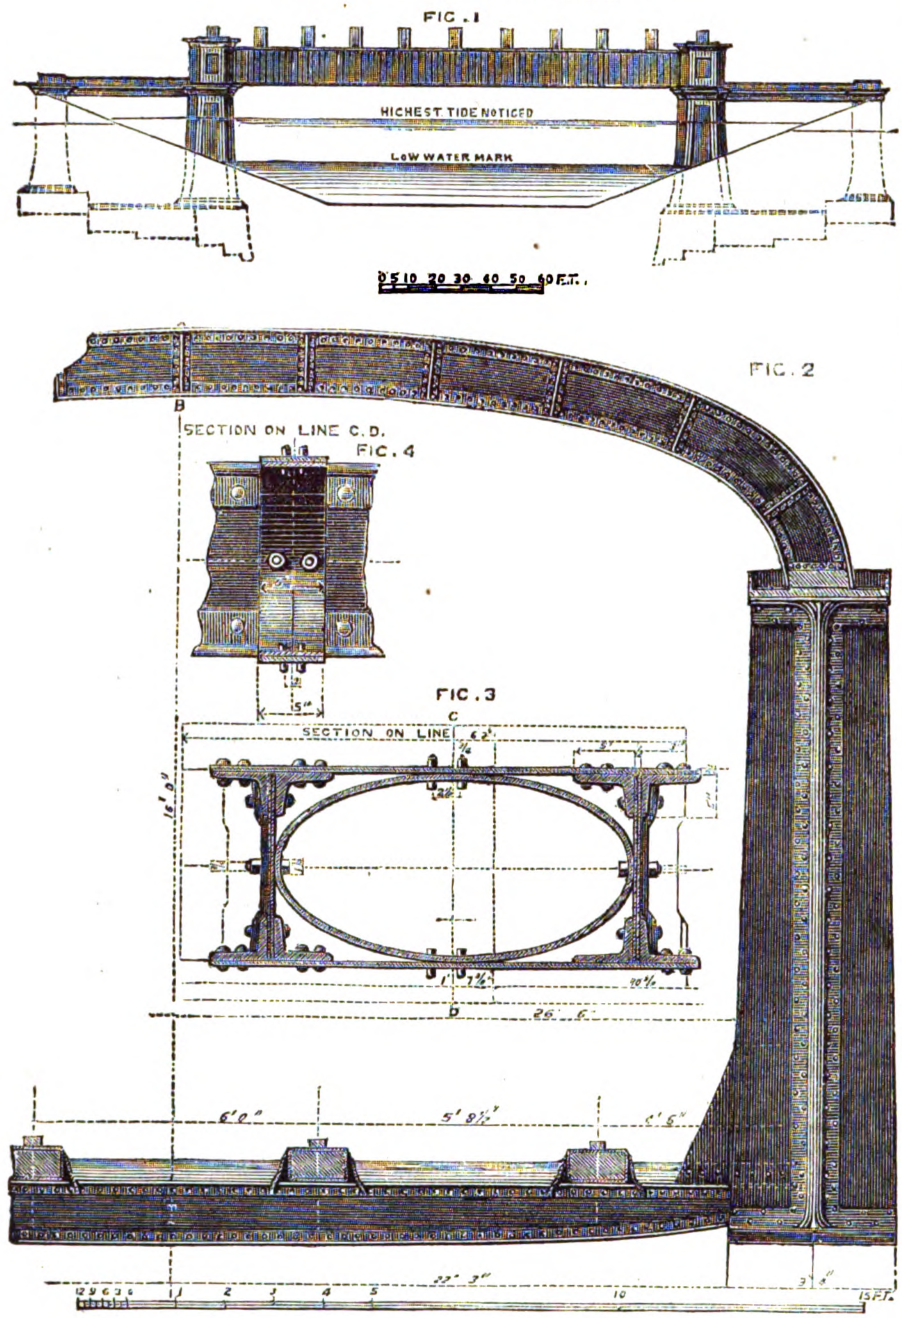
* This agrees with the formula given by J. B. in the *Engineer* of the 2d October, 1863, page 200.

THE CHRONOTHERMAL STOVE.

MESSRS. LUCK, KENT, and CUMMINGS, of Regent-street, Waterloo-place, have recently brought out a stove, which is distinguished by the simplicity of its construction, and the admirable manner in which it effects the purpose it is intended to fulfil. It consists of a cylinder of cast iron, about 20 in. long and 9 in. in diameter, pierced with several apertures at each end. This, which forms the external portion of the stove, is mounted on an ornamental base, fitted with a sliding register for regulating the draft through the fire, and surmounted by a suitable lid or top, of handsome design. An internal cylinder, one or two inches smaller than the external case, within which it is suspended, contains the circular grate on which the fuel rests. The fire, kindled at top, heats the metal with which it is in contact nearly red hot. The air contained in the space between the two cylinders is rarefied, and flows out into the apartment through the holes in the upper portion of the external case, while cold air rushes in through those beneath to make up the deficiency. The passage of the air over the heated plates is so rapid that the particles of dust in suspension cannot become ignited, and there is in consequence a complete absence of that peculiar scorched odour, so common in rooms heated by the ordinary stove. The products of combustion are conveyed away by a small pipe proceeding from the side of the stove into any convenient flue. The calorific powers of the apparatus are very considerable, 12 lbs. of Welsh coal, sufficing to warm a large hall for an equal number of hours. The fire, once ignited, requires no further attention whatever during the day. When burned out, the inner cylinder is withdrawn by a suitable hook, and another filled with fresh fuel substituted, so that the operations of the stove can go on uninterruptedly for weeks together if necessary. From what we have seen of its powers, we feel no hesitation in pronouncing the chronothermal stove one of the best things of the kind before the public.

Captain Kirkham, of the bark "Edwin and Lizzie," who has just arrived in the Mersey, gives particulars of one of those rare instances of a whale striking a vessel direct on the stem, and which in the case of his ship nearly caused her to founder, so tremendous was the shock she received. The "Edwin and Lizzie" left Prince Edward Island with a cargo of timber, and on the 12th of October, in lat. 45.1 N., long. 27.8 W., at half-past one in the afternoon, was struck by a large whale. Part of her cut-water was carried away, and the main stem cut right through to the wooden ends. This terrible blow, as might be expected, caused great alarm on board the vessel, and so rapidly did she leak that the pumps were instantly manned, and kept going night and day without intermission. Fortunately, they were equal to the emergency, and though the "Edwin and Lizzie" (a new vessel) had 7 ft. of water in her hold, she was brought safely to the Mersey and docked.

THE PIALLEE BRIDGE, INDIA.



THE PIALLEE BRIDGE, INDIA.

THE Piallee bridge, which is of the plate girder construction, crosses the Piallee River, India, with one span of not less than 170 ft. between the abutments. It is single, the double line of rails being borne by one pair of girders, as shown in fig. 2, which have a depth of 13½ ft., and are stiffened on the upper edge by a cast-iron flange. This is the only case in India in which cast iron has been thus combined with wrought-iron girders. The different ratio of expansion of the two materials would probably be fatal to the general adoption of mixed structures, the stability of which might be endangered in places where the range of temperature is great and changes rapid—as for instance, in the Punjab and the Upper Provinces. In Bengal, however, where the range of the thermometer is not much greater than in England, and the humidity of the atmosphere checks rapid radiation, this objection is of less force. The great depth of the girders has necessitated the adoption of some contrivance to prevent buckling, and accordingly they are connected at intervals of 19 ft. by elliptical arched ties of boiler plate, arranged in pairs and stiffened, as shown in figs. 3, 4. The width of the roadway between the girders is 22 ft. 3 in.

The bridge was designed by Mr. J. A. Longridge, and erected under the superintendence of Mr. J. Sturmer, the resident engineer of that part of the line.

At the point at which the bridge crosses the Piallee, the river flows in an artificial channel. It formerly made a bend at this point, which carried the stream about 400 ft. to the west of its present course, and it thus became necessary to carry the embankment, which forms the western approach of the bridge, across the old channel, the bottom of which was 60 ft. below high-water mark, and 83 ft. below the level of the line. Accordingly, in July last year, the new cut having been excavated, and the lower end of the bend bunded with sand-bags to facilitate silting, the embankment was commenced by throwing in earth from the western bank. The soil of the locality, like that of the Sunderbunds generally, however, is a soft loam, highly absorptive in water, so that the earth thrown in speedily formed a semi-fluid slush, which flowed out on both sides, filling up the old channel, and then flowing out at one or both ends into the river. No efforts could succeed in raising the embankment above the level of high-water, and a quantity of bamboos which were laid down with a view to impede the lateral motion of the earth, after settling together with the embankment, reappeared after a few weeks some 200 ft. off on the line of outflow. At length, in February of the current year, finding that there was no hope of the earth attaining sufficient solidity to bear the weight of the embankment as hitherto attempted, Mr. Wall adopted the expedient of constructing a great float, on the same elementary principle, although differently applied in construction, as that adopted with so much success by George Stephenson at the Chat Moss.

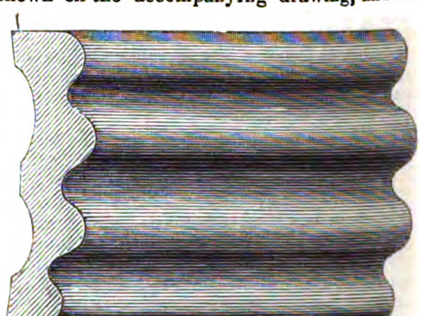
Two rows of piles, 100 ft. apart, were driven in along the sides of the proposed embankment across the old channel, and the earth having been excavated to a depth of 3 ft. or 4 ft., the base of the excavation was floored with palm trees laid longitudinally, and bonded together with hoop iron, the extremities of which were carried round the piles, and thus a flexible box was formed on which the embankment was to be raised. The upper and lower ends of the piles were also tied together with those of the opposite row with hoop iron. Upon the structure thus formed the earth was then thrown. The float yielded slightly under the pressure, but beyond this stood firm, and the embankment was speedily carried up to the required height of 20 ft. above high-water level. Thus at length a difficulty has been overcome which at one time threatened to render the actual line impracticable, or to involve the alternative of necessitating a second bridge of equal dimensions to that crossing the cut. Not less than 4,000,000 cubic feet of earth were expended on this work or about four times the amount theoretically required for an embankment on the same dimensions, had the materials been of a stable character.

GRAY'S IMPROVEMENTS IN BEATERS FOR THRASHING MACHINES.

MR. W. GRAY, machine knife manufacturer, Sheffield, has recently patented the following improvement in beaters for thrashing machines.

The revolving beater or drum in ordinary thrashing machines consists of several longitudinal bars firmly secured and attached to arms or spokes, or to the periphery of wheels affixed to a central shaft or axis with which the beater or drum revolves.

This invention consists, firstly, of the rolling of steel of any description, or wrought iron in the shape or design, or any similar shape or design, shown on the accompanying drawing, and the



application of such rolled steel or wrought-iron bars to be used or applied as beaters for thrashing machines on the drum, concave, or breast plate. The patentee does not confine himself to the precise shape as shown on the drawing, as the same may be altered or modified as circumstances may require; these beaters, made of steel or wrought iron, being superior and more durable than those now generally used.

Secondly, this invention consists of fluting or grooving in steel or wrought iron the surfaces of

the longitudinal bars of the beater in the manner shown on the drawing, in perspective, by which the shape or design is clearly shown, the parts grooved or hollowed out underneath being merely for the purpose of reducing the weight.

TRIAL OF HER MAJESTY'S SCREW LAUNCH "EXPERIMENT."

The official trial of this little craft, which has been fitted by the steam factory department of Portsmouth dockyard expressly, by order of the Admiralty, in order to obtain certain data relative to the merits of the double or twin screw system, took place on Monday in Stokes Bay.

The "Experiment" is a first-class line-of-battle ship's launch, 42ft. in length, and of proportionate breadth and depth. Her engines and boilers occupy a space in the centre of the boat of only 6ft. 11in. by 4ft. 4in., the nominal horse power of the engines being 3, the length of the stroke of piston 6in., and the diameter of cylinder 4in. The total weight of engines and boilers, with platform, coal-boxes, &c., and with boilers fitted, is 2¼ tons. The cylinders are brought on to each side of the boiler and drive their independent shafting through each quarter with screws attached to the latter of four blades, each screw having a diameter of 2ft., and a pitch of 3ft. 4½in. The draught of water of the launch, at the commencement of the trial, was 2ft. 6in. aft, and 1ft. 9in. forward. The launch steamed out of the harbour at 10 a.m. against a strong flood tide, and excited considerable surprise in the minds of those on board by the manner in which she ran over the strong adverse tide. The measured mile was reached, and the little vessel was at once placed upon her speed trials, which she accomplished as follows :—

	Time. m.	Time. s.	Knots.	Pressure of Steam. lbs.	Rev. of Engines.
First run ...	8	3	7·453	55 to 50	290
Second run	10	57	5·479	55 to 50	280
Third run...	7	15	8·275	60 to 55	200
Fourth run	11	28	5·232	60 to 55	280
Fifth run...	7	19	8·200	60 to 58	290
Sixth run...	11	10	5·373	59 to 55	280

Mean speed of the six runs, 6·742 knots.

The revolutions of the engines averaged 290 at 60 lbs. pressure of steam, and with that pressure the experiment will realize a good seven knots. On Monday, from a cause which can be easily remedied in future, the steam, as will be seen by the foregoing figures, could not be kept at 60 lbs., and consequently the vessel lost in speed, although it was almost impossible for anything to be more satisfactory than the speed she actually attained. Indeed, it has become a question worth noticing, while referring to speed alone, whether by thus dividing the propelling power of a vessel in the substitution of two for a single screw, an additional speed of the ship through the water is not gained. The advocates of the principle, such men as Commanders Symonds and Selwyn, R.N., say that full 20 per cent. is gained. Reverting, however, to the actual results obtained by the trial of the "Experiment," on the conclusion of the speed trials the vessel was next tested in making circles as follows :—With both engines going ahead at full speed, with the rudder acting, a complete circle was made to starboard in 1 min. 9 sec., and to port in 1 min. 13 sec. The circle was next made with one engine shut off, and with the port engine standing (the helm still being brought into use) a circle was made in 1 min. 31 sec., and with the starboard engine shut off in 1 min. 27 sec. Reversing the motion of the respective engines, and with the starboard engine going ahead and the port astern, the circle was made in 2 min. 9 sec. Repeating this experiment, but with the starboard engine astern and port ahead, the circle was made in 1 min. 43 sec. The diameter of the circles made, as near as could be ascertained without actual measurement, was, with both engines going ahead and rudder acting, rather under three times the length of the launch ; with one engine shut off, rather over that distance ; with engines reversed, and screws, therefore, working opposite ways, the launch turned on a pivot just abaft her centre, and within her own length, gradually working spirally and astern. The foregoing results confirm in a remarkable degree the trials made during the past 12 months on the Thames, by Messrs. Dudgeon, of Limehouse, which have attracted so much attention in the naval and scientific world, and which have been attended and officially reported upon for the information of the Admiralty by their inspecting engineer afloat, Mr. John Dinnen.

TABLES RELATING TO LOCOMOTIVE ENGINES.

We copy the following useful tables from the *American Railway Times*. They should find a place in the engineer's note book :—

The tractive power required to move any load upon a level railway is found by dividing the square of the speed in miles per hour by 171, and to the quotient adding 8, and multiplying the sum by the load in tons.

Speed in Miles per hour.	Tractive power needed, load being 50 tons.	75 tons.	100 tons.	250 tons.
12	442	663	884	2210
15	465	691	931	2328
20	517	773	1034	2585
25	582	874	1165	2912
30	663	994	1326	3315

Table showing the tractive power required to overcome grades with different loads.

Grade in feet per mile.	Load in tons. 1.	50.	75.	100.	250.
20	8	424	636	848	2122
40	16	848	1272	1696	4244
60	26	1272	1910	2546	6340
80	33	1697	2545	3393	8489

To find the tractive power needed to overcome any grade, we multiply the load by the rise per mile, and divide the product by 5280, the number of feet in a mile.

Table of factors which multiplied by the total piston pressure give the tractive power of the engine in lbs.

Diameter of Driver.	Stroke in inches. 18.	20.	22.	24.
4	2386	2652	2918	3182
4¼	2250	2500	2750	3000
4½	2151	2390	2593	2830
4¾	2012	2235	2459	2682
5	1910	2122	2334	2546
5½	1736	1929	2122	2315
6	1591	1768	1945	2122

The above are all decimals, and are got by dividing the double stroke by the wheel circumference, both in inches.

Table of piston pressures for different cylinders, and different steam pressures.

Diameter of Cylinder.	Area of Piston.	Whole pressure on both pistons, at 100 lbs.	110 lbs.	120 lbs.	130 lbs.
16	201	40,220	44,242	48,264	52,062
18	254	50,900	55,990	61,080	66,170
20	314	62,840	69,124	75,408	81,692

Relative volumes of steam under different pressures.

Steam pressure.	Relative volume.	Steam pressure.	Relative volume.
80	359	120	249
90	323	130	231
100	293	140	216
110	269	150	203

That is, at a pressure of 100 lbs. per inch, each cubic foot of water will make 293 cubic feet of steam.

Table giving the amount of surface obtained by 100 tubes, of different dimensions.

Length of tube in feet.	Square feet of surface in 100 tubes, diameter of tubes in inches being 1½.	1¾.	2.	2¼.	2½.
10.0	392	457	524	589	655
10.5	411	480	549	618	687
11.0	431	503	576	647	720
11.5	451	526	602	677	753
12.0	471	549	628	705	786

Table showing the mean pressure in the cylinder, for different percentages of admission, and different initial pressures.

Initial pressure in lbs.	Mean cylinder pressure cutting off at ¼.	⅓.	½.	⅔.	¾.
100	54	65	83	93	95
110	60	72	91	102	105
120	66	79	99	112	114
130	72	86	108	121	124

That is, if we cut off the steam at 50 per cent., which has a pressure at entering of 120 lbs. per inch, the mean pressure throughout the stroke will be 99 lbs.

PHOTOMETRICAL POWERS OF THE ELECTRIC LIGHT AT BOSTON.

The battery used consisted of 250 Bunsen elements, having each an acting zinc surface of about 85 in., and grouped in five battalions of 50 each, was arranged in the dome of the State House, and the carbon light and the photometric apparatus prepared for the purpose were placed in line across the same apartment, commanding a range of about 50 ft.

In view of the immense power of the light, as observed in the previous experiment, I substituted for the 20-candle gas burner, used at that time as the standard of comparison, a unit ten times as great, formed by the flame of a kerosene lamp placed in the focus of a small parabolic reflector, and throwing its concentrated light on a photometric screen of prepared paper fixed infront of it, at the distance of 5 ft. Before the observation, the lamp and reflector were so adjusted as to make the light cast on the near side of the screen equivalent by measure to the action of 200 candles.

This was done by the intervention of a kerosene lamp fitted up with a bridge of platinum wire for defining and restricting the height of the square flame. Such a lamp I find of frequent use in ordinary photometry, as, when suitably adjusted, it gives the light of about eight standard candles, and thus transfers the measurement in the photometer to the wider divisions of the scale. Being suspended in a balance of peculiar construction, its rate of consumption enables us to correct for any slight departure from the assigned illumination. The lamp thus regulated was placed with its flat flame 12 in. from the screen, while the lamp in the reflector was distant 60 in., and the flame of the latter was adjusted until the effects on the screen were equalized.

A platform supporting the standard lamp and screen at the assigned distance was arranged to slide on a horizontal graduated bar, extending directly towards the carbon points so that the screen should receive the rays from the electric light and from the reflector perpendicularly on its opposite faces. In making the observations, the platform was moved to and fro until the illumination on the opposite sides of the screen was judged to be equal, and then the measured distances of the two antagonizing lights from the screen gave, by easy computation, their relative illuminating power.

By a series of such observations, it was found that the carbon light had a force varying from 52 to 61 times that of the lamp with reflector, making it equivalent in illuminating power to the action of from 10,000 to 12,000 standard sperm candles pouring their light from the same distance upon the surface of the screen. This, it will be remembered, is the effect of the unaided carbon light sending its rays equally in all directions from the luminous centre, and falls vastly short of the illuminating force of the cone of collecting rays which was seen stretching, like the tail of a comet, from the surface of the great reflector. Judging from some recent experiments on the power of such a reflector to augment the intensity of the light emanating from its focus, there can be no doubt that, along the axes of the cone, when brought to its narrowest limits, the illuminating force of the carbon light, as displayed on the State House, could be rivalled only by that of several millions of candles shining unitedly along the same line.

In the above described observations a thick screen was necessary, on account of the great intensity of the lights to be antagonized. I need hardly say that the different colour of the two lights added much to the difficulty of the measurements. But, by marking in each case the extreme limits on either side, it was practicable to adjust the screen pretty accurately to equality of illumination.

The only previous experiment of precisely the same kind which I can recall is that of Bunsen, cited in the books, which was made with a battery of 48 elements. In this the photometric equivalent of the carbon light was estimated at 572 candles, or nearly 12 candles to the cell. My observations show a power more than three times as great, or about 40 candles to the cell—a difference due, no doubt, largely to the more intensive battery at my disposal, and the cumulative effect of its arrangement. I suspect, too, that the elements in Bunsen's observatson were of inferior size ; but on this point I am without definite information.—*Silliman's Journal.*

STEAM FRIGATE "NIAGARA."

The late George Steers, who was esteemed one of the most skilful modellers and constructors in the world of fast-sailing vessels, designed and built the frigate "Niagara," the largest in the American navy. Her model is held to be faultless for securing speed ; but with naval men she has never been a favourite, and under steam her speed has been only moderate. Her engines have been held to be deficient in power ; and for about a year past, when her services might have been most valuable on the southern coast, she has been laid up at the Charlestown (Mass.) navy yard, undergoing extensive repairs. Her old engines have been taken out and more powerful ones substituted ; and it is now expected that her speed will be greatly increased. The new armament of this frigate surpasses that of any other vessel in the world for weight of metal. It consists of twelve 200-pounder Parrot rifled guns on the spar deck, and twenty-four 11-inch smooth-bore guns for throwing hollow shot and shell on the main deck. The old system of arming war vessels was based upon furnishing them with the greatest number of guns possible; the modern method consists in supplying a much smaller number, but of much greater calibre.—*Scientific American.*

SYMONDS' SCREW SHIPS.

FIG. 1

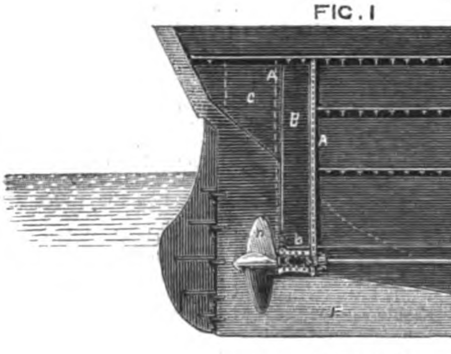


FIG. 2

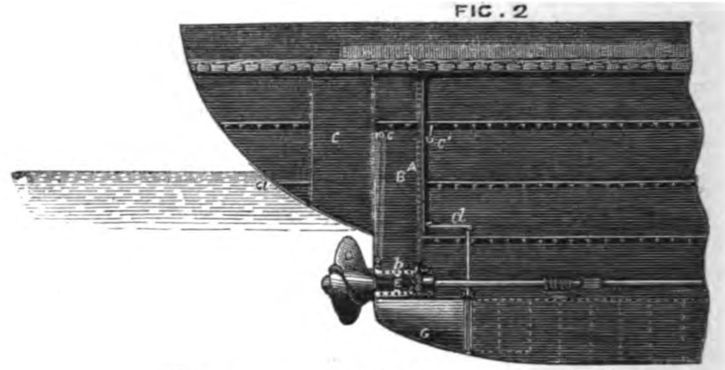

FIG. 3

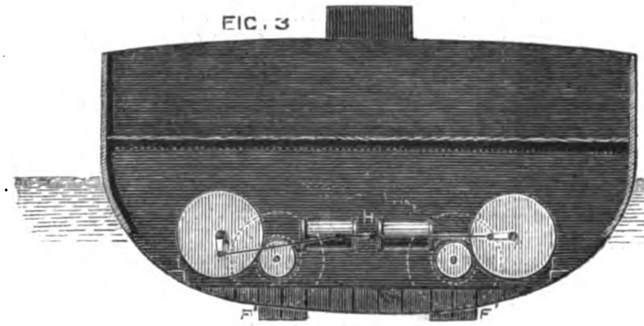

FIG. 4

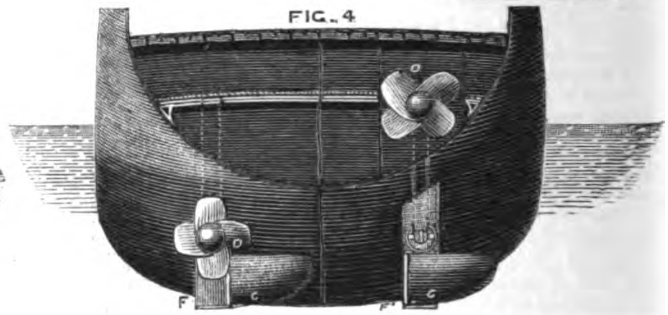


SYMONDS' IMPROVEMENTS IN THE CONSTRUCTION OF SCREW SHIPS.

This invention, patented by Thomas E. Symonds, Commander R.N., relates to twin or double screw ships built of iron, and having one or more keels, each screw being overhung or having no outer bearing.

In constructing ships according to this invention, two transverse bulkheads are formed across the stern part of the ship, the aftermost of these bulkheads being immediately before the screw, and a well-hole for receiving each screw is also formed under the counter and abaft the transverse bulkhead.

For the purpose of enabling overhung screws, according to this invention, to be raised vertically, the patentee mounts or fixes each screw upon a short length of shaft, which is supported by and free to revolve in a long bearing formed by two half-carriages, which when brought together form a tube, which may be filled with lignum vitæ strips or other bearing and wearing surfaces. These half-frames when combined form the carriage, which, sliding in a vertical frame or guides between the transverse bulkheads, enables the screws to be raised vertically, so that the ship may sail without the obstruction offered by the screw propeller. Each screw may be raised separately. The inner end of the short shaft, upon which the screw is mounted, may be fitted with the ordinary form of cheese-head coupling. The withdrawing the screw from the water or the raising and lowering may be effected by means of chains or ropes and pulleys, or any of the well-known mechanical means may be adopted for that purpose. The foremost of the transverse bulkheads is fitted with a stuffing box for the screw shaft, and one part of the cheese-head coupling projects therefrom. The apertures for the screws are fitted with flaps or shutters opening outwards (or they may be made to slide), for the purpose of closing the opening at the bottom of the screw hole, so as to ensure a clear delivery of the water, whether under steam or sail. The overhanging end of the screw or one of the blades may have a hole cast or formed therein for the purpose of enabling the screw to be "fished," or to assist in withdrawing it or hauling it up.

For the purpose of withdrawing the overhanging screw horizontally from off the screw shaft in double screw vessels, the shaft is made at the outer end sufficiently large to enable it to be bored or otherwise made hollow, for the purpose of receiving the shank of the screw, or a short length of shaft upon which the screw has been fitted, and by means of a gib and cotter passing through slots formed in both the screw shank or shaft and the hollow part of the main shaft within or forward of the stuffing box, or between the outer and inner bulkheads, or forward of the stern bearing, thus the key or other means of securing the overhanging screw in its place may be withdrawn and the screw released.

By the arrangement of bulkheads forming the after termination of the hull in the manner described, the patentee is enabled to give additional strength to the ship as a structure; and by the arrangement and disposition of the stern part externally and of the rudders in double-keeled vessels, to avoid the necessity for any after stern-post, upright, or framing piece abaft the screw propeller, or any opening or void, such as exists in ships of war and other vessels, between the fore and after stern-posts, which impairs the steering qualities of the ship.

In iron screw vessels having double keels a rudder is placed in the line of each keel, and nearly in a line with each screw shaft, and the tillers connected together so as to enable them to work simultaneously, but they may be readily disconnected for the purpose of being worked separately.

In the accompanying drawing, fig. 1 is a side elevation of the stern part of a ship of war of the same dimensions as the "Warrior," constructed according to the present invention, showing the arrangement of transverse bulkheads, the arrangement for lifting the screw, and the trunk or well-hole for each screw; this vessel has two screws and a single keel and rudder. Fig. 2 is a longitudinal section, and fig. 4 an elevational stern view in two sections of a double-keel iron ship having two screws and two rudders fitted according to this invention in a ship of large size suited for war purposes.

In the two sectional views in fig. 4 the one is so taken as to show the screw in its usual position, and also the trunk or space up which the screw shaft travels; the other section shows the screw raised, the screw well-hole, and the cheese-head coupling or bearing in the trunk or box projection which springs from the keel for the purpose of receiving the outer length or screw shaft:

Fig. 3 is a transverse section, showing an arrangement of engines for driving the two screws independently, to admit of manœuvring the vessel with or without the aid of the rudders; and although in this section a peculiar arrangement of engine is shown, in which it is intended to employ two pairs of engines (each of two cylinders), and wheel gearing is also intended to be employed for allowing of the engines working slow. The patentee does not confine himself to this arrangement.

In the several figures, A is the transverse bulk-head hereinbefore referred to in the stern portion of the hull, and which is in every case carried up above the deep load line, and in vessels of light draft it is proposed to carry it up to the deck line in screw ships where the screw is raised vertically; B is the narrow trunk or space in which, in double-screw ships having overhung screws, the short shaft and the main bearing are made to slide or travel up and down as shown; C, the well-hole, in which the screw is raised and withdrawn when out of use from its working position; D, the screw, which may be varied in form; E, the shaft upon which the screw is mounted, and which shaft may be fitted and moved and detached from the screw in either of the manners hereinbefore described, and in each case the mode or method of fixing the screws, and of connecting the short shaft to the main shaft, and the mode of lifting or moving it, as also of connecting and disconnecting the screw, is shown in accordance with this invention; F, the keel of the single-keel double-screw ship, and F^1, F^1, the keels of double-keel ships; G, G, the rudders of double-keel double-screw ships, the mode of working these rudders being shown; H, an arrangement of horizontal engines and gearing for driving the two screws, which may or may not be adopted; a, a, are flaps for closing the screw well-hole, and b, the long bearing and carriage containing the short length of screw shaft, and which is fitted so as to slide vertically into and out of gear with the cheese-head coupling on the screw shaft; c and c^1 are the pulleys or sheaves for lifting and lowering the screw; d, the tiller of the rudder; e, the thrust block of the screw shaft.

WILSON AND SMITH'S IMP[ROVEMENTS] IN FURNACE GRAT[ES]

This invention, patented by Mes[srs. ... Wil]son, engineer, and J. Smith, bake[r, ...] relates to a novel arrangement of ... ing furnace fire-grates, and consis[ts ...]

...rawing, ... as circu... made of st... more dura... of fluting ... the surfaces ...

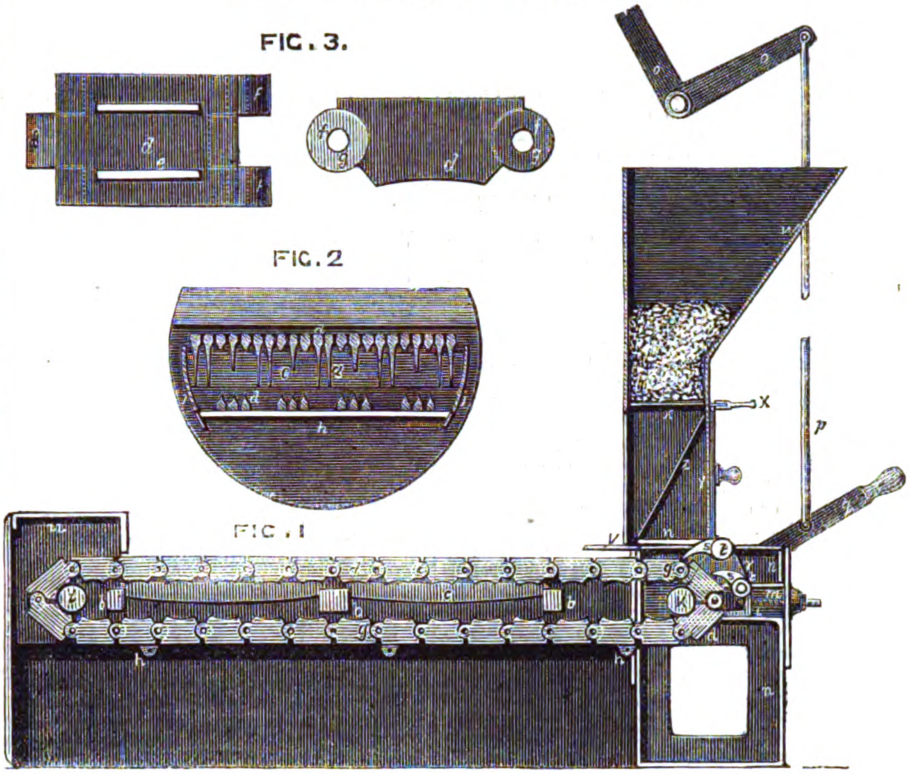
employment of stationary bars and travelling bars, placed alternateley to form the suport for the fuel, and such bars, when so arranged, may be distributed either lengthwise or across the furnace.

The stationary bars are of the usual kind, and rest on bearers as at present. The travelling bars are made of short links or short bars jointed at suitable distances apart so that they form an endless chain, and for this reason they are termed "chain bars." At either end of the furnace fire-grate, or at the sides should the bars be placed transversely, the chain bars are carried by and pass around a drum or shaft, from the surface or surfaces of which are a number of projecting arms or tappets to fit into or between the links of each separate endless chain of bars. Motion is communicated to the drum or shaft in any convenient manner from any available source, so that when in use one-half of the chain bars of each endless chain will be moving immediately in contact with the fire and the other half in the ashpit. In some cases the patentees employ under the surfaces of the chain bars, in contact with the fire, and parallel with the stationary bars, so that they may rest on the same bearers, smaller stationary bars to keep the chain bars from "sagging," and to maintain them in a uniform position in relation to the stationary bars. Instead, however, of the chain bars travelling continuously from end to end or from side to side in one direction by a rotary motion, they may have communicated to them by cams, or any other well-known change gear attached to the drum or shaft, a reciprocating or an intermittent motion so that they may travel any desired length in one direction and as far or a shorter distance or length back again, or they may travel a short distance, then stop, and so on alternately.

Fig. 1 of the accompanying drawing is a longitudinal section (taken through between the stationary and travelling bars and looking on the chain bars); and fig. 2 a transverse section; the arrangement being such that the motion given to the chain bars is a forward one for a short distance, after which they are allowed to stop, and so on, moving and stopping alternately. Like letters designate the same parts in all the views.

a represents the stationary bars, shown of the usual shape, in two lengths, and resting on cross bearers *b*, all of which, with the exception of those at the ends, are notched and recessed to allow the stationary bars to pass through, and the carrying bars *c*, to prevent the chain bars *d* from "sagging," to rest thereon. The chain bars *d* are made of a good width and with air apertures *e* therethrough. At the under side, the projecting pieces *f* (see enlarged view, fig. 3) fit into each other, and are coupled by pins or bolts *g*, preferably, with the heads rivetted down, thus forming articulated bars; *h* shows transverse rollers for supporting the chain bars underneath; *i*, the back chain bars supporting roller, at freedom to rotate in its bearings which are part of the framework *j*; *k*, the front supporting shaft resting in two screw sliding nuts *l*, so that by the screws *m* passing through the front framework *n*, the chain bars may be tightened or slackened at pleasure. Motion is communicated through or by the bell crank *o*, connecting rod *p*, and lever *q*, secured on or to the front supporting shaft *k*, at the rate of about two double (that is up and down) strokes a minute. Crank brackets (shown only in fig. 1) to every chain of bars, or two large crank brackets, one at either side, are secured to the shaft or drum *k*. These crank brackets *r* carry for each chain of bars two impulse pallets *s* jointed on pins *t*, or on rods passing from one side to the other, and the motion above referred to, which is reciprocating, should preferably give a throw sufficient to enable the pallets *s* to move the chain bars half a link each stroke; *u*, a guard of metal or fire-brick to prevent the fuel from being carried over the back of the fire-grate; *v*, the dead plate; *w* shows a hopper with supply control slide *x*, door *y*, and coal guide *z*, which latter can be slid upwards into the hopper out of the way when the "firing" is done by hand; but as there is nothing new in the hopper or its immediate connections, it need not be further described.

WILSON AND SMITH'S FURNACE GRATES.



YATES' IMPROVEMENTS IN THE MANUFACTURE OF ARMOUR PLATES.

THIS invention, patented by Mr. T. Yates, Rotherham, ironmaster, has for its object improvements in the manufacture of large and heavy armour plates or blocks and bars suitable for the protection of fixed and floating forts or batteries, whereby economy of labour is obtained and a stronger and cheaper armour plate or block is produced.

According to the present mode of manufacturing armour plates they are rolled or hammered generally to a uniform thickness or nearly so, or to an even taper or nearly so, the edges of the plate being rough and uneven, and requiring to be afterwards cut off or trimmed in order to square up the plate, which operation is both costly and wasteful.

According to these improvements, the operation last referred to is, for the most part, dispensed with, the plate being rolled or hammered with smooth edges, and therefore requiring little or no further trimming or cutting. For this purpose it is proposed to hammer, stamp, or roll the plates, blocks, or bars from the metal of which the armour plate or block is to be manufactured in metal moulds or frames, which impart the desired size and shape or nearly so to the armour plates or blocks, the sides of the mould or frame confining the material and preventing it from spreading whilst under the influence of the hammer or rolls beyond the size required, and leaving the edges of the plate or block, comparatively speaking, even and smooth. During the process of hammering or rolling the plate (and more particularly in the hammering) the necessary indentations or projections required for uniting, fastening, or attaching the plates may be formed.

In some cases where very strong re-

YATES' ARMOUR PLATES.

FIG. 1.

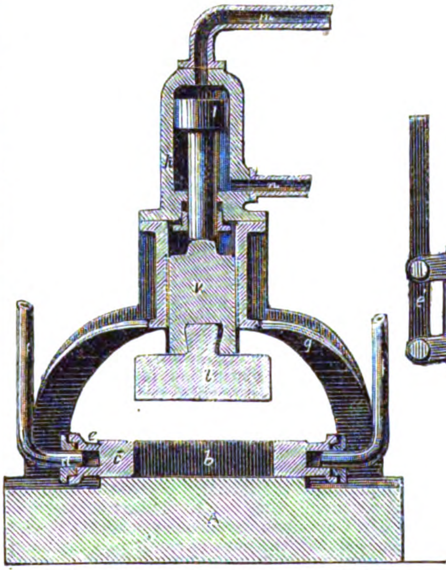


FIG. 2.

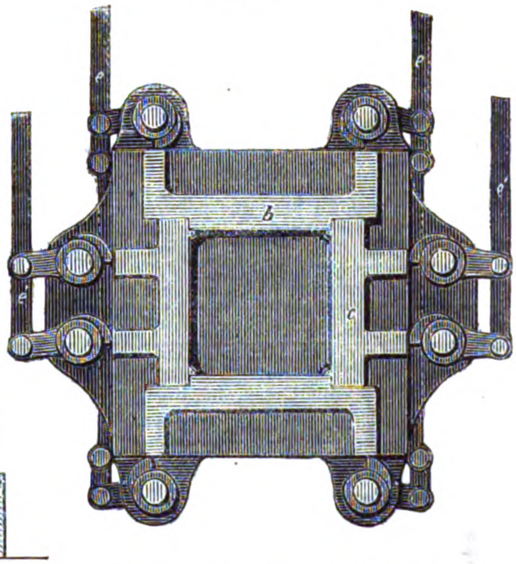

power is required, it is proposed to cast on to the plates made as above described a block or backing of cast iron or other suitable metal, the wrought-iron plate being either in a cold or hot state (but it is preferred to have it hot, so that the two metals will amalgamate), and placed in a suitable mould of the proper depth and form according to the desired thickness and shape of backing to be cast on the plate. This mould may be made either plain or with indentations or projections on the sides to facilitate the locking together of the plates or blocks, or the cast metal block may be prepared first and provided with projections or indentations upon that surface which is afterwards to be brought in contact with the wrought-iron plate, and the wrought-iron plate is then hammered or stamped upon it whilst in a soft or plastic state, and is thereby forced into and around the indentations or projections in the cast metal block so as to secure the two metals in close contact.

Fig. 1 represents a vertical section of one arrangement of machinery for stamping and shaping armour plates or blocks in moulds or frames by the aid of hydrostatic or hydraulic power. In this machine a perpendicular as well as a lateral or oblique pressure is applied to the plate or block by special and separate hydrostatic or hydraulic presses and rams, which, by their conjoint action, reduce the rough block to the desired shape and dimensions without the necessity of trimming the edges of the plate or block after it has been forged, excepting where very fine joining is required.

A is the anvil block, upon which slide horizontally in proper grooves or guiding slots the four lateral blocks *b*, *b*, and *c*, *c*, impelled by separate cylinders and rams *d* of their own; *f*, *f*, represent the pipes leading to the several hydrostatic or hydraulic cylinders; *q*, *q*, are the moulding surfaces which give the desired form to the edges of the blocks and which enclose the rectangular or other shaped cavity or mould *p*, in which the plate or block is deposited direct from the carriage or truck, as hereinbefore described. The upper frame *g*, *g*, is secured by bolts and keys to the anvil block, and carries the vertical cylinder *h*, ram *i*, and slide block *k*, which latter carries and guides the hammer *l*; *m* is the pipe which supplies the main cylinder *h*; two or more of such cylinders may be employed when large plates or blocks are to be stamped; *n* is the escape and back lift pipe. In working the press, the metal is placed in the mould or enclosed space *p* whilst in a plastic state, and the two opposite side blocks *b*, *b*, are then simultaneously pressed up to the ends of the blocks *c*, *c*. The side blocks *c*, *c*, are then immediately and simultaneously pressed home, thus completing the pressure upon all the sides of the plates and shaping those sides to the desired form. The large hammer *l* is then brought down upon the entire mass, finally reducing the metal to the form and thickness required. On removing the stamped plate or block it will be found when cool ready to be secured in its place after a very slight dressing of the edges.

Fig. 2 represents in plan a modified arrangement of mechanism for actuating the side blocks *b*, *b*, and *c*, *c*, a series of reciprocating cam levers *e*, *e*, and e_1, e^1, being employed in lieu of hydrostatic pressure. The main perpendicular stamper or hammer may, however, be worked either by hydrostatic or direct steam pressure.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post-office orders made payable to Mr R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the Editor, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—You have before now published an invention or two of mine, but under a different name. I have now one concerning balloons which I shall make public, so soon as I have completed the calculations. In order to complete them I require information on one or two minor matters. If you, or any of your correspondents, can give me this information, or Mr. Coxwell's address, I should be much obliged. I think I can give a clearer circumstantial account of the accident at Basford-park (I was on the spot) than has yet been given. My invention is quite a new idea, and will quite do away, I think, with all accidents arising from the valves. The following are the points of information I require:—

1. The weight of the top valve, name or kind of valve.
2. The same particulars with regard to the bottom valve.
3. Weight per yard super. of the silk.
4. Is it not customary only to fill the balloon, just so as to rise, or much more than enough?

I should be much obliged if you could enlighten me, and am, obediently yours, Alfred Edwin, C.E.

27, Castle-street, Dover, Kent.

E. A. Cartar.—Your invention is ingenious. We may perhaps illustrate it in a future number.

C. Y. (Nottingham).—The length of a safety valve lever is usually so proportioned that the effective pressure on each square inch of the valve equals the force of the spring balance. Thus, a valve with an area of 6 square in. should have a lever giving 6 to 1.

F. C.—The area of grate must depend on the quality of the coal which you use. Try 80 square in. per nominal horse-power, Glasgow rule.

Seaman.—Illustrated this week.

THE RIFLING PRINCIPLE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Mr. Cheverton's scientific eccentricities are so well known to the generality of your readers, it would not be worth while noticing his theoretic *fancies* on gunnery, if his observations did not afford the opportunity of saying a word on precision of language—an object essential to fair discussion, but one on which that gentleman has very confused ideas. He delights in verbal criticism, the most irksome and unprofitable kind of literature, which usually has no other foundation than the critic's misapprehension or misrepresentation of a writer's meaning.

The same words often have or are used with different meanings. With scientific terms, in the use of which there is much uncertainty and affectation, this is peculiarly the case. Many violent controversies owe their origin to the different sense in which words are interpreted. The best rule is to employ them in the sense of their obvious and popular meaning.

According to Johnson, "momentum" is the "force *or* quantity of motion in a moving body." Here, then, we have two meanings. I prefer the former—*the force in a moving body*—consisting of velocity and weight combined; and this is the common acceptation of the word. The latter meaning—*the quantity of motion*—refers to velocity only. Mr. Cheverton confounds the two, hence his misapprehension of a plain statement. In a few words, I will set him right. By momentum, I mean the force of the moving body, as represented theoretically by the square of the velocity multiplied by the weight. I say that velocity and weight are the elements which constitute that force, and by way of illustration, and to keep in the mind of the reader the characteristics of the two elements, I call velocity the "vis viva," because it is *active*, and I call weight the "vis inertiæ," because it is *passive*. The distinction is intelligible, obvious, and convenient, and this distinction is so important, as applied to the effect of rifled projectiles, that I am glad I provoked Mr. Cheverton to bring the subject prominently forward.

Equal quantities of momentum, the products by calculation of varying quantities of velocity and weight, ought *theoretically* to give the same results, but *practically* they don't. This is not my *opinion*, as Mr. Cheverton erroneously asserts; it is, as I clearly stated, the *positive result* of experiments at Shoeburyness. I am sorry for the theory, but it shares the fate of the theories of the sages of Laputa—it is thwarted by disturbing causes, never dreamt of in their or Mr. Cheverton's philosophy. That gentleman's ardour in support of a principle reminds one of the enthusiastic French republican, who exclaimed, "Let the colonies perish rather than abandon a principle;" and when it was shown to him that facts were opposed to his theory, he contemptuously replied, "So much the worse for the facts."

"Everything else being the same, the penetration" (of projectiles into armour plates) "will be the deepest, when the material is most immoveable." With profound amazement I read these words, propounded as an axiom, in Mr. Cheverton's letter. To leave no doubt of his meaning, he explains that this opinion, which he unequivocally stamps with the seal of the settled conviction of his mind, refers to "the rigidity or yielding of the materials, whether such yielding be of an elastic or non-elastic character." I do not wish to hurt his feelings by demolishing a hobby which he is riding to death. I will not give an opinion; I will confute him with *facts*, which perhaps he will treat with the sovereign contempt of the republican French *savant*.

In the course of last summer the Iron Plate Committee made experiments for the purpose of determining the comparative resistance of rigid and yielding (elastic or non-elastic) material. Four plates of the same thickness and dimensions were fastened in the same manner, with through bolts, to four different kinds of structure—one of solid slabs of cast iron, one of solid blocks of granite, one of solid oak, one of alternate layers of cork and kamptulicon, a preparation of india rubber. The different degrees of rigidity and elasticity named by Mr. Cheverton were exactly represented. These plates were fired at successively with a 40-pounder gun, with the same charge of powder, the same weight, form, and diameter of projectile, and at the same range, 200 yds., "*Everything else*" (but the rigid or yielding nature of the materials) was, as Mr. Cheverton desires, "*the same*." The results of the trials were as follows:—

On the most rigid and unyielding structure, that of cast iron, the penetration was *nil*, the shot making only a slight mark on the iron plate. On the structure next in degree of rigidity, that of granite, there was a slight indentation about a quarter of an inch. On the yielding, but not elastic structure, the solid oak (3 ft. to 4 ft. in thickness), the penetration was *through the plate* and about 15 in. into the wood. As to the elastic structure, the projectile penetrated and smashed through the plate and everything behind it.

It really is a waste of time and of your valuable space to dwell so much on a point, so obvious to common sense, as the superiority of rigid over elastic or yielding resistance to projectiles. But the pertinacity of Mr. Cheverton, and other theorists, who erroneously assimilate the resistance to projectiles, at high velocities, to the resistance to other forms of force or pressure, makes it desirable that publicity should be given to the practical results of experiments. If there were any truth in the theory that "penetration will be the deepest where the material is most immoveable," it would follow, that the thicker a plate of iron is, the deeper would a projectile penetrate into it, which is a manifest absurdity.

I am afraid I shall again shock Mr. Cheverton's "fancies" by stating that the smashing and penetrating effects of a shot are co-equal against the same structure, the force of the projectile at the moment of impact and its form and sectional area being the same. The contrary opinion is a fundamental error of the Armstrong theory, which it was one of the objects of my letter, printed in the Mechanics' Magazine of the 16th inst., to point out and prove by experiments therein referred to.

What, I will now ask, is to be thought of the following passages in Mr. Cheverton's letter? Referring to my explanation, that rifling was the cause of the long range of the American guns, he *first* says, "the long range is ascribable to the application of rifling to guns, as a practical expedient to secure the parallelism of a long projectile to the end of its flight"—an enunciation, in scientific phraseology, of the effects of rifling, or rather of the rotary motion resulting from rifling, which is known to every tyro in gunnery. He then adds, "it (the long range) is not (as I stated it was) ascribable to the rifle principle." What, then, is the rifle principle? Is it anything else but what he himself describes? No comment is necessary on so palpable an equivocation. I can afford to bear these petulant remarks. Mr. Cheverton, it appears, cannot forgive me for having, on former occasions, showed that he misapprehends and misapplies theories, and is deficient in practical knowledge. It has with truth been said, that an ounce of practice is worth a ton of theory.

Civilian.

BOILER EXPLOSIONS.

Sir,—During a tedious epistolary discussion, to which I referred in my letter to you a fortnight ago, Mr. Clark sent me an incoherent communication, which, with others from the same source I,

not long afterwards destroyed, partly in pity for its author; but I am willing to accept his present reproduction of it as literally exact. I will say nothing of its dignity, nor of the calm, philosophic tone which pervades it throughout. It professes to recapitulate the whole history of the "percussive theory," and it contains only two dates—viz., that of the first publication of my views, September 16, 1859, and that of the first publication of a single surmise, by Mr. Clark, February 10, 1860. From the presbyterian division of this "recapitulation" into paragraphs down to eighteenthly, these are evidently intended to represent the order in which the events which they profess to narrate took place. But No. 7, which contains the essence of Mr. Clark's notions of explosions, comes *before* No. 9, which relates to the explosion on board the "Great Eastern." Now, Mr. Clark has lately said that he "started the projectile theory" shortly after that explosion, viz., on the 12th or 13th of September, 1859, in a conversation with Mr. Holley and myself, although I have proved an *alibi*. Furthermore, Mr. Clark said nothing of "the violent separation of steam and water dashing the contents like small shot against the surfaces of the boiler," until the evening of November 5, 1859, nearly two months after the explosion, I then noted down the suggestion as he made it, with a few others upon the same subject, upon the margin of a slip of newspaper, on which was printed "The *Times*, Friday, November 4, 1859." I kept this for some months, and many of my friends saw it. Had Mr. Clark advanced this idea before, I should have introduced it into my writings; but it nowhere appears in them until in my tract of 1860. So much for "No. 7, D.K.C., roused."

I will now briefly comment upon this "recapitulation."

No. 1. Perfectly true; and many others had said and recognized the same things.

No. 2. True.

No. 3 is erroneous in the use of the word "all" instead of "some of." I had told Mr. Clark, a few weeks before the "Great Eastern" explosion, that when the parts of a boiler had been once torn asunder, *from any cause*, the additional steam disengaged from the water would account for the distance to which they would be thrown. This was but a repetition of what I had written in the *American Engineer* in 1857.

No. 4. Last lines of paragraph. This was Mr. Clark's constant and irrelevant reply *after* I had explained to him the "Great Eastern" explosion.

No. 5. So I had "strangled" all theories based on electric action? Then why did Mr. Clark, knowing this on February 13, 1860, write you on May 3, 1861 (Mechanics' Magazine, Vol. 74, No. 1,969, page 307), that "the writer in 1859 appears to have had some notion of electrical action in his mind"?

No. 6. I doubt not that I "hammered" at Mr. Clark, "made no progress" with him, "wondered" at his difficult perception, and "said there must be something yet not understood" by him. This is my general recollection of discussions extending over two months, until he, at last, appeared quite convinced.

No. 7. Already noticed; the date of this arousal being November 5, 1859.

No. 8. I often asked Mr. Clark if he did not believe the weight of the steam, considering its velocity, to be sufficient to produce a *blow* causing explosion. I pressed this strongly upon him on September 14, 1859. On the 4th of November following, Mr. Clark did give me, and for the first time, "various illustrations," with which I was much pleased. I presume Mr. Clark recollects giving me these illustrations in his *new* office, into which he had only removed while I was absent in Paris from October 15 to November 1. If he does not, his former assistant does. This gentleman, I may add, heard nearly all our previous conversations upon the subject. No leaders upon explosions, "lucid" or otherwise, appeared in the *Engineer* for about a year after the time when Mr. Clark gave me his "various illustrations."

No. 9. Indeed! "D. K. C. *gave*" the "circumstances" of the "Great Eastern" explosion to "Z. C. and A. L. H"! Mr. Clark, who, for anything I know, may have never seen the "Great Eastern," "gave the circumstances" of the explosion to Mr. Holley, who, while in conversation with the present Duke of Sutherland, Lord Alfred Paget, Mr. Nasmyth, Mr. Francis Pettit Smith, and Mr. McConnell, *saw* the chimney go up before his own eyes, and who spent several hours in examining every detail of the wreck! To go on, I was not and am not now "at home" with Mr. Clark's views, although I think I can see their impracticability pretty clearly. And so Mr. Galloway, with his incredible *pressure*, was right? Mr. Clark may think so if he likes.

No. 10. The precise condition in which heated water rises upon a sudden removal of pressure, is still a moot point. It may all go into fine, hot mist,* and the word "steam" might be hastily and not altogether inappropriately used to express this.

No. 11. The article *Steam*, ably compiled by Mr. Clark from the writings of Mr. Scott Russell, Professor Rankine, and others, has often been of service to me, and I was certainly glad to obtain it.

Nos. 12 and 13. True, although the facts might be better expressed.

No. 14. When and how did Mr. Clark show his "resentment"? As nearly as I can ascertain, it was in January, 1860, when he found that others were giving me credit for what he had, in more than one conversation, freely acknowledged to be mine alone. The manner of his "resentment" was in privately claiming to have supplied me with the ideas contained in a long series of articles, some of which, I may now say, were written partly with the hope of convincing *him*. Gross provocation and noble resentment!

No. 15. This is magnanimous, for I have given Mr. Clark occasion to think much more severely of me than as a "compiler," &c.

No. 16. In direct contradiction with Nos. 1 and 2.

No. 17. See reply to No. 10.

No. 18. This was the first and only contribution by Mr. Clark to the present or any other theory of boiler explosions.

As to my history of our conversations, Mr. Clark raises nothing in dispute of it beyond a general denial, the value of which may be judged by two others which immediately follow it. He denies having used an oath. The conclusion of his last letter to me, in February, 1860, was "damn Harshman." This, which I showed to many of my friends, may not have been an oath: it was, however, a curse. Mr. Clark denies that he acknowledged appropriations from the *Engineer* in the *Encyclopædia*. The acknowledgment endures, however, in plain characters at the bottom of the 625th page of the 20th volume. Of equal force are all Mr. Clark's denials.

As to Mr. Clark's postscript, I should be ashamed to quote it. The language of prize-fighters, always disgusting, is, if possible, more so in your columns; and I can only express my astonishment at the infatuation of a man who employs such language in the attempt to establish for himself a claim to a scientific truth, and in the presence of men like Lord Brougham, the Astronomer Royal, Professor Faraday, Dr. Fairbairn, Professor Rankine, Dr. Joule, and hundreds of other distinguished men of science, who, I have reason to know, read the Mechanics' Magazine.

I am the defendant in this action in which Mr. Clark now first publicly attempts to wrest from me my title—for four years undisputed—to the now received theory of boiler explosions. As in all litigation, the defendant is expected to reply upon every point, and he must avail himself of his privilege of the "last word," or abandon his suit. I thus defend my title, most unwillingly, and I shall heartily rejoice when the time for summing up this case arrives. This correspondence costs me much valuable time which would never be given to it, except under a strong sense of duty to myself. I feel that I do myself little credit in noticing one who has nothing to lose and everything to gain in this matter, but every line that he or I write at once passes into history. I must needs, therefore, have patience.

I may now close by reverting to the fact that all that Mr. Clark has ever published upon the *rationale* of boiler explosions (with the exception of his contribution to the *Encyclopædia*, duly acknowledged to the *Engineer*, and reflecting at nearly every line the ideas of my tract of April, 1860) was his note to you of February 10, 1860. My writings, beginning in 1857, embodied the present theory in September, October, and November, 1859, and in my tract of April, 1860, and they have been dedicated to an almost constant illustration and defence of that theory ever since.

I am, Sir, your obedient servant,

Zerah Colburn.

3, Upper Bedford-place, Russell-square,
October 24, 1863.

* See the Mechanics' Magazine for September 18, 1863, page 652.—[Ed. M.M.]

BOILER EXPLOSIONS.

Sir,—As regards the difference of opinion on particular theories brought forward in your magazine, by those who, we presume, have both time and abilities for such a scientific research, I think it would be more beneficial to your readers and to the public were those gentlemen, instead of sparring to no purpose, to point out some plan to prevent boiler explosions, according to their different dogmas. I would advise a simple experiment to be tried, to satisfy those who may feel interested. Have two lightly-constructed small round vessels, to which attach a large plug-cock; fit them to a boiler of high-pressure steam; fracture both vessels; fill one with water, draw the triggers, and I think it is quite evident which will show the largest compound fracture.

Yours truly,

John L. Winton.

13, Gladston-street, St. George's-road,
Southwark, Oct. 26, 1863.

"THE GREAT EASTERN."

Sir,—The remarks of your correspondent Mr. Kennedy, in your journal of the 9th inst., are, to a certain extent, very sensible. I fully concur with him in curtailing the length of the "Great Eastern;" but I would slice off 80 ft., being 30 ft. more than he proposes—most certainly strip her of her paddle-wheels and paddle engines—and give her two screws, one under each quarter. To prove a great success, the screws should feather, thereby economising fuel and time; but to dispense altogether with her rudder, would be very unwise—fuel exhausted, no steering. The style of rig suggested by Mr. Kennedy I believe to be correct.

Mr. Kennedy evidently possesses good inventive abilities. Can't he give us nautical men a good *substantial feathering* screw? We dread the lingering and unsatisfactory operation of connecting and disconnecting "which the screw in present use involves;" and after the latter has been accomplished, we have the mortification of dragging the screw after us, thereby depriving the ship of two or three knots an hour; in fact, screw propulsion will never be fully developed until we have the screw to feather; the sooner the better, both for the pockets of the owners and those who have the command of screw auxiliaries.

I am, Sir, your obedient servant,

T. Box.

Rotherhithe, October 20, 1863.

Meetings for the Week.

Mon.—*Royal Inst.*, General Monthly Meeting.

Wed.—*Geological Soc.*, 1, "On Some Ichthyolites from New South Wales," by Sir P. de M. G. Egerton, F.R.S. 2, "Notes on the Geology of a Portion of the Nile Valley, &c.," by A. L. Adams (communicated by L. Horner, Esq., at 8 p.m.

Sat.—*London Assoc. Foremen Engineers*, "On Hollow Castings in Iron," by Mr. W. W. Oubridge, at 8 p.m.

Miscellanea.

A prospectus has been issued of the Lundy Granite Company with a capital of £100,000 in shares of £5. The object is to work the stone quarries in Lundy Island, North Devon. The company have a contract to supply the stone for the first section of the Thames Embankment.

The plates out of which the "glacis" plates which are to encircle the base of the "Royal Sovereign's" turrets on her upper deck are to be made, have been received at Portsmouth yard, and handed over to the steam factory department to accomplish the work. This will be one of great difficulty, and will only be eventually accomplished, if carried out in the way now proposed, in the utter destruction of all the shot-resisting qualities of the plates. The proposed plan is to take the now perfect masses of metal in all their rough strength, carve them out in all manner of semicircular lines, and then plane them down from their inner 5½ in. thickness of inner edge to nothing on their outer edge or circumference, thus destroying the skin, fibre, and strength, or shot-resisting power, of the metal, and making it certain to break up under even the shot of an ordinary 68-pounder like pottery ware. If this course is persistently pursued the cost will be enormous, and the ship cannot be finished before March next. By a rougher and simpler disposition of the [illegible] ing to form the glacis, ten times the str[illegible] tained, with th[illegible] mount of [illegible] nd at one- [illegible] f th[illegible] ompleted

in one-third of the time. It is but just to the steam factory department to say that its chief is fully aware of the vast difference in the two plans, and in favour of the shorter and more economical one. The "Royal Sovereign" is but an experimental ship after all.

The Channel fleet will shorty make a further, and, perhaps, a more practical trial of the seagoing qualities of the different ships composing Rear-Admiral Dacre's command, by taking a trip to the Tagus. The fleet will probably be absent from England about six or eight weeks.

Tenders have been issued by the War Department for the contract supply of a large amount of pig-iron, to be delivered at the royal gun factories at Woolwich arsenal, to be prepared for the manufacture of the new species of naval guns, fifty of which are ordered to be commenced forthwith. The gun, it is stated, will be somewhat similar to the 100-pounder smooth-bore gun which withstood a severe experimental test at Shoeburyness, at the commencement of the past summer, and which was afterwards tried with success on board the gunnery ship "Excellent," at Portsmouth.

We learn from the Liverpool papers that an important addition has just been made to the class of steamships that are designed for the passenger trade between England and Australia. The magnificent vessel we allude to, the "Royal Standard," has been built expressly for Messrs. H. T. Wilson and Chambers, the owners of the Liverpool and London "White Star" line, by Messrs. Palmer Brothers, the celebrated iron ship-builders, of Newcastle-on-Tyne, especially for the passenger trade. The "Royal Standard" is a craft of beautiful symmetry and great size. In total length she measures 283 ft. over all; her moulded breadth is 40 ft.; her depth of hold is 27 ft. 6 in.; and her gross measurement tonnage is 2,000 tons. She has been built on exceedingly fine lines, with a keen cut-water, a well rounded waist, clean run aft, and a sweetly moulded stern. In these respects the "Royal Standard" possesses all the best characteristics of a first-class clipper, her general trim and rig being those of the best order of passenger clippers; to these highly-desirable attributes it is only necessary to add that this beautiful vessel has an auxiliary screw propeller, worked by steam engines of 165-horse power, but capable of being worked up to 500, and furnished with surface condensers and every modern improvement, thus ensuring, as far as human means can do, a vessel that is certain to perform even the longest voyages with steady celerity and regulated speed. In the trip from Newcastle to Liverpool the "Royal Standard" gave every satisfaction, Captain Allen reporting himself in every way pleased with her steaming and sailing qualities, stating that she "steered like a boat," and that in whatever part of the ship he was in could not detect the vibrations from the engines. She steamed eight knots against a strong head breeze, 10½ to 11 under stay-sails, and 12½ with the wind abeam.

Aluminium bronze, which is an alloy of aluminium with copper, has for some time been in use in Birmingham, and it has been worked into a variety of useful and ornamental articles—for instance, watch cases, watch chains, brooches, and many little trinkets—and the metal looks so gold-like that when nicely polished it cannot by the eye alone be distinguished from gold. Now we have it applied to another purpose. Messrs. C. T. Lutwyche and Son have patented the application of it to the manufacture of writing pens. They profess that pens made of this metal are, in appearance, equal to those made of gold, and are quite as incorrodible; that they write as smoothly as quills, whilst the price is so reasonable that any one may purchase them.

Graham's Shoal, between the island of Pantillaria and the town of Sciacca, on the coast of Sicily, which first appeared in 1831, has again risen out of the sea.

The last idea of Paris is a plan in alto-relievo of the whole of Europe, not in maps of models, but actually raised out of the ground. A garden is to be set aside for the modeller, who is taking "Mont Blanc," 15 feet high, as his *point de depart*, is to raise in just proportion around it the rest of the mountains of Europe, pour the seas into their proper places, and intersect the whole with roads, canals, railways, and telegraphs. A steam-engine is to act the part of moon, and regulate the tides. It will be a geographical garden, where "he who runs may read."

The *Army and Navy Gazette* states that on the express requisition of the Amiralty the War Department has ordered the manufacture of 50 muzzle-loading guns to be at once commenced in the Royal Arsenal. Since the introduction of steel inner tubes, the coil system, which was first carried out with modern appliances by Professor Treadwell in America, and more lately advocated by Mr. Longridge, C.E., and Captain Blakely, R.A., has been developed by Sir W. Armstrong, so that it may be safely asserted that the Woolwich establishment is able to turn out built-up guns which are well worth their cost. We do not assert that these built-up guns are better or even equal to the solid forgings of Krupp, but we believe they will be good guns.

Mr. Richard Hugh Hughes, of Hatton-garden, in a letter to the *Daily News*, says:—Your readers are already aware that I have patented a system of ventilation exactly opposed to the previously conceived notions upon the subject; instead of producing the current by exhaustion, I propose to produce it by propulsion. Now, the system in use has proved to be imperfect, and all that I ask is to be afforded an opportunity of proving, whether or not I have made any nearer approach to perfection. I only desire that my invention should have a fair trial, and I will willingly permit its use in a colliery, free of all fees or royalties whatever, that its merits may be tested. It appears to me so evident that by substituting propulsion for exhaustion, we shall keep the gas in the coal until the moment it is broken by the workmen, instead of drawing from every possible point as we do at present, that I am very sanguine of the results which are obtainable; and I shall be disinclined to acknowledge that I am wrong in principle, until my invention has had a practical trial, or until some valid argument against it is given by your correspondents.

Prosperity prevails among French ironmasters in consequence of fresh orders received from Italy, Spain, Russia, and Egypt. The construction of docks at St Ouen and the Government works at the Palais de Justice, the New Chamber of Commerce, the Conservatoire des Arts et Metiers, the School of Mines, and the orders received from the company formed for lighting Caen with gas, are keeping them fully employed. The preparations for bringing the waters of the Dhuys to Paris, and the construction of reservoirs, are conducted with great spirit. Artistic ironworks are now carried to great perfection in France, as may be seen by the very handsome railing just finished for the Museum of Napoleon III. at Amiens.

Mitchell's waterproof floating mail-bag has been exhibited in the Exchange News-room, Liverpool, under the direction of the inventor. It is a strongly-constructed bag, made of the best "duck," or sailcloth, thoroughly impregnated with caoutchouc, and consequently completely waterproof. From this quality it is more or less buoyant on account of the quantity of atmospheric air it contains, and so becomes valuable. The specimen exhibited in Liverpool, is about 3 ft. long, 1 ft. broad, and about 6 in. deep. This bag was well filled by a miscellaneous collection of materials, such as may be expected to find their way into a mail bag. They consisted of newspapers, numerous loose papers, a comparatively large number of books, and to give weight in an additional degree, two common building bricks, the whole forming a very heavy mass compared with the size of the bag. The whole, however, was buoyant, and on opening the bag it was found that not a drop of moisture had permeated into it. The inventor also states that he has arranged a means by which the whole contents of a ship's mail-room may be made buoyant, and connected so as to form a raft or buoy in case of necessity.

A large Martin boiler, intended for the United States gunboat "Sunapee," burst in the Washington Iron Works, at Newburg, N. Y., where it was being tested. Several persons were fatally scalded, and the buildings were demolished. This is the first case on record, we think, of this sort of boiler exploding. The loss, amounting to 25,000 dols., falls on the company.

A company has been formed for carrying on the manufacture and extending the sale of "Muntz's Metal," which for many years has superseded, to a great extent, the use of copper for marine and other purposes. For this purpose it is proposed to raise a capital of £600,000, in 30,000 shares of £20 each, but it is not expected that more than £12 10s. per share will be called up. Mr. Muntz takes a seat at the direction, and receives 2,500 paid-up shares, representing £50,000, for the good-will of the business, whilst the company obtain the freehold of the works with all the plant at a valuation, the stock in hand being taken at current prices on the day of transfer. The works are in full and extensive operation in Birmingham, they are returning large profits, and the company will come into their possession without the suspension of a single day's working.

The Paris correspondent of the *Building News*, states that a project is talked of for the formation of a submarine railway between France and England. According to the *Journal du Havre*, this railway is to be, not under the sea, but in the sea. A tube or entire tunnel is to be constructed, divided into 100 compartments. This tube, which will traverse the railway, is to be surrounded with another iron tube as a protector. The interval between the two tubes is to be fortified with brick-work. Means of obtaining air will not be wanting, that part of the problem having been solved, at least, theoretically, by those who have proposed a tunnel under the Strait.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgment:—

Steam Engines, &c., 756, 781.
Boilers and Furnaces, 736, 763.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 759, 769.
Ships and Boats, including their fittings, 776.
Cultivation of the Soil, including agricultural implements and machines, 751, 654, 667.
Food and Beverages, including apparatus for preparing food for men and animals, 737.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 746, 757, 758, 773, 778, 780, 782.
Buildings and Building Materials, 752, 772.
Lighting, Heating, and Ventilating, 747, 753, 755, 762, 764, 765.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 734, 741, 743, 749, 760, 766, 775.
Metals, including apparatus for their manufacture, 738, 739, 742, 745, 748, 771, 774, 777.
Chemistry and Photography, 731, 732, 733, 761.
Electrical Apparatus, 768.
Warfare, 750.
Letter-Press Printing—*none*.
Miscellaneous, 735, 740, 744, 770, 779.

731. W. Lorberg. *Improvements in the treatment of rags and obtaining valuable chemical products from the animal fibre therein.* Dated March 18, 1863.

These improvements relate to the treatment of—1, mixed fabrics containing vegetable fibre and animal fibre, known in the trade as linseys, stuffs, bodies, challies, and the like; 2, printed cotton goods, known as chintzes, furnitures, prints, and the like; and have for their object the separation or recovery, the cleansing and bleaching, of the vegetable fibre, and obtaining valuable chemical products from the animal fibre. For the purpose of separating the vegetable from the animal fibre, he steeps the goods in a solution of caustic, alkali, soda, or potash, which disintegrates or dissolves out the animal fibre, such as wool, silk, hair, without sensibly attacking the vegetable fibre. This solution also decomposes or breaks up some of the colours or dyes, and removes most of the dirt, grease, or other impurities contained in the rags. The selection of alkali depends upon the uses for which the wool liquor, or solution of wool, is to be employed; and the strength of the alkaline liquor is of course varied according to the quality of the goods operated upon. The action takes place in the cold, but heat accelerates it. After this process the goods are subjected to strong pressure, in order to force out the disintegrated wool, together with the alkaline liquor retained in them, and are then thoroughly washed in plenty of water, after which they are immersed in an acid bath, containing from 1 to 5 per cent. of acid, generally sulphuric, where they must remain for a longer or a shorter period, until the decomposition of the more refractory colours is complete. They are again washed, and ultimately submitted to the action of one or more of the well-known bleaching agents, such as chloride of lime, chloride of soda, or potash, sulphurous acid, when they will come out white and clear. The spent liquor from the first process containing the wool and other animal matters in solution, and being, therefore, very rich in nitrogen, he employs for the manufacture of manure, ammonia, or cyanogen compounds. *Patent abandoned.*

732. A. Morel. *Improvements in apparatus for generating carbonic acid.* Dated March 18, 1863.

Carbonic acid gas may be easily produced by pouring an acid on a carbonate, such as marble, chalk, or bi-carbonate of soda; and this very facility of production creates variations of pressure in the generator, which requires continual attention, as also a gas-holder for containing the gas. This invention relates to an improved generator of

carbonic acid which is self-supplying, and regulates itself at a constant pressure without any supervision, and producing a regular current of gas without the aid of a large gas-holder or regulator. *Patent completed.*

733. J. D. and A. P. WELCH. *Improvements in bleaching and reducing and brightening the colour or tone of dyed straws, plait, and straw.* Dated March 18, 1863.

This invention consists of improvements in the treatment of straw plaits and straw, by first dyeing or staining them, and then bleaching and reducing their colour, whereby the straw acquires a brighter appearance, the colour being reduced to a neutral and uniform tint. *Patent abandoned.*

734. G. HASELTINE. *Improvements in the manufacture of boots and shoes.* (A communication.) Dated March 19, 1863.

This invention relates to the fastening of the soles to the uppers of boots and shoes by means of rivets that are incorporated with the sole, and that pass through the edges of the insole and the upper, and have the points of the adjacent rivets clenched in opposite directions. *Patent completed.*

735. E. LEVER. *An improved composition for the coating and preservation of canvas and other materials to make them waterproof and non-inflammable.* Dated March 19, 1863.

This consists of a composition or compound of about 4 parts quick lime, 3 parts glue, 3 parts whiting, 3 parts gum arabic, 1 part Epsom salts, and 4 parts alum, dissolved in a sufficient quantity of water to make it of a proper consistency for the purpose required, or the material to be operated upon. *Patent completed.*

736. H. WILDE. *Improvements in the construction of steam boilers.* Dated March 19, 1863.

The patentee claims the placing of a fillet or band of copper or other suitable metal between the joints formed by the overlapping of the plates, or between the plates and angle irons, and allowing the said fillet or band of metal to extend beyond the joints in the interior of the boiler, in the manner and for the purpose described. And he also claims for the same purpose the coating of boiler plates, at or near the seams, with copper or other suitable metal. *Patent completed.*

737. H. O. HAUGHTON. *Improvements in machinery for drying and cooling grain and seeds.* (A communication.) Dated March 19, 1863.

For the purposes of this invention the grain or seed is fed from a hopper, or other suitable source of supply, on to one end of a perforated floor or platform at the bottom of an enclosed chamber. The quantity supplied is regulated by a slide or suitable valve. The upper part of the chamber is covered by an arch or double inclined roof, where there is an outlet for the passage of the air and vapours arising from the grain or seed which is spread on and gradually moved along the perforated platform or floor. The grain or seed is caused to move on the perforated floor by means of an apparatus carried by two endless chains, which are caused to circulate within the enclosed chamber, and above the perforated floor or platform. This apparatus consists of axes or shafts which are placed transeversely across the chamber. On each end of each of these shafts or axes is a flanged wheel, and these wheels are supported by and run along two pairs of parallel guides or bars fixed on each side of the chamber, and these pairs of guides or bars are arranged one over the other, so that when the wheels of each of the shafts or axes arrive at the end of the upper guides or rails, they descend on to and run along the lower guides or rails and then again ascend to and run along the upper guides or rails. These endless chains pass round chain wheels at each end of the chamber, so that by giving motion by any suitable power to one of the axes on which the chain wheels are mounted, the whole of the apparatus is put in motion. On each of the shafts or axes is mounted a series of short axes at right angles with those which carry them, and on each of these short axes two flaps are mounted, in such manner that the two flaps may radiate from their axis, and be set to a greater or less inclination thereon as the endless chains travel. These sets of flaps are moved along the perforated floor or platform, and by so doing they move more or less of the grain or seed spread thereon from one end to the other end of the chamber, according as the pairs of flaps are for the time set to a greater or less angle to each other on their axes. Below the perforated floor or platform means of obtaining and supplying heated air are applied, which consist in fireplaces from which proceed tubes or metal flues taking an indirect course to the chimney, so as to obtain extended heating surface in the chamber below the perforated floor or platform. It is preferred to have two fireplaces, and to divide the lower part of the lower chamber longitudinally by two partitions; also to have at each side openings with a sliding cover or valve to regulate the introduction of air into the lower chamber. Between the perforated floor or platform and the heated pipes or passages are inclined plates having a longitudinal opening between them, up through which the heated air passes, and thence through the perforated floor or platform, and amongst the grain or seeds spread thereon, and such heated air and the vapours rising therewith from the grain or seed are carried off by a fan at the opening in the roof before mentioned. The grain or seed as it arrives at the end of the perforated floor or platform descends on to an inclined sieve or perforated plate, down which it slides, and from the lower end of which it is delivered to a suitable shoot. *Patent completed.*

738. J. SAUNDERS and J. PIPER. *Improvements in apparatus employed in the manufacture of tin and terne plates.* Dated March 19, 1863.

For the purposes of this invention, in order with more advantage to carry on that part of the process where tin or terne plates are used to pass through heated grease to equalize and to remove the excess of the coating, apparatus is employed arranged and combined in the following manner:—A pair of rollers is placed and revolve in a shallow trough or vessel, and they are mounted in bearings which are carried by levers which are pressed together by springs, so as to produce the desired pressure or nip to the rollers. The grease is retained in this trough or vessel to any desired height by means of an overflow-pipe, the delivery end of which may be raised or lowered to any required point. There is also a separate grease trough at one end, in which the necks of the rollers, their axes, and clutch-boxes revolve, from which also there is an overflow pipe. The axes which give motion to the rollers are driven by friction surfaces, which are pressed together by a weighted lever. Below the trough in which the rollers revolve, and in connection therewith, there is a descending trunk, the lower end of which descends to the bottom of another trough, into which the tin or terne metal removed from the plates descends, and from it such metal is removed. There are openings at the lower end of the trunk through which such metal flows into the receiving trough below, whilst the melted metal in the lower trough supports the grease in the trunk, and in the upper trough or vessel. The coated plates are placed in succession into a portion of the upper trough or vessel, which is divided off by a partition, and each plate as it is introduced descends into the trunk till its lower edge rests on a lifting bar or cradle therein, and such plate is then caused to assume a vertical position in the cradle by fingers which are mounted on an axis above. These fingers give way as the plate descends in an inclined position into the trunk, and then the fingers by pressing against the plate cause it to assume a vertical position in the cradle, which is below the nip of the rollers. The lifting bar or cradle is then raised by a lever handle, which brings the upper edge of the plate to the nip of the rollers, so that by the revolution of the rollers the plate is raised out of the grease, which is kept heated by any suitable means. *Patent completed.*

739. S. L. CROKER. *A new and useful or improved yellow-metal sheathing nail or spike, which, by means of a nail-cutting engine, is cut from yellow sheathing metal.* Dated March 19, 1863.

Yellow metal, when in a cold state, cannot be used for the manufacture of cut nails or spikes in a nail-cutting machine, the great frangibility of the metal preventing the nails or spikes from being cut and headed. The patentee has discovered that by heating it to redness, or thereabouts, and while so heated introducing it into the nail or spike machine, it may be safely cut up into nail blanks, and each of the said blanks can be headed by the machine. After the nails or spikes, as the case may be, have been thus made, they are to be again heated to or about to redness, and when so heated they are to be plunged into cold water. In consequence thereof their brittleness will be so overcome as to render them capable of being bent or driven without that danger of being broken under such operations as the common cast composition nails or spikes would be subject to. *Patent completed.*

740. C. WEBSTER and W. FORGIE. *Improvements in apparatus for the purpose of clearing out the interior of foul chimneys or flues when on fire or otherwise.* Dated March 19, 1863.

This apparatus consists of a series of steel or other hard malleable metal strips or material, by preference, about one-eighth of an inch thick, and three-fourths of an inch broad, and divided into eight or other suitable number of equal parts about eight inches long, more or less, according to the size of the apparatus required. These parts are formed into semi or half circles upon edge, with saw teeth cut thereon, and attached to or mounted upon a steel spindle or rod of metal, by preference about half an inch in diameter, and about twelve inches long, having joints near each end to which the parts previously described are attached, part at one end and part at the other, so that the unjointed ends of the strips meet and overshoot each other, and although coupled together they are quite at liberty to expand by means of self-acting springs, which cause the apparatus when at liberty to do so to expand into a globular shape, but when compressed they contract into a smaller compass, and thereby the apparatus adapts itself to the interior form of the chimney or flue, or any inequalities thereof. The apparatus is worked by means of a series of rods made of steel or other hard material screwed to the apparatus, and in succession to one another, by which it is moved up and down the chimney or flue, and if the same is on fire, a lever handle is employed to work the apparatus to and fro in the flue, by which great power can be imparted thereto, and at the same time permit the operator to stand at a safe distance from the burning material as it is discharged from the flue. *Patent completed.*

741. G. H. SMITH. *Improvements in sewing machines.* Dated March 19, 1863.

This invention relates to the means of producing the feed motions of certain sewing machines known by the name of double or back-action machines, and consists in the combination of a lever working on a universal-jointed or double-action fulcrum, and actuated by a double tappet, on which lever is suspended from or near the end thereof a feeder, with a universal or double-action joint at the upper part of the feeder, admitting of its being moved either forwards or backwards, across the arm of the machine, or at right angles to such direction of motion. This feeder acts in combination with a double guide capable of being moved and set as required to form a guide way for the feeder in either of its respective motions, and a bevel formed on the operating end of the working lever, or on the end of a fixed spring, and impelled by the said lever for the purpose of acting on a bevel formed on the feeder, in order to produce the required motion of the same, either in the direction of the length of the arm of the machine, by the one bevel sliding over the other, or in the direction across the arm by the pressure of one bevelled piece on the other. By means of this combination, the feeder is worked through the several motions required for propelling or feeding the article to be sewed, either across or up the arm of the machine by the agency of one lever, instead of requiring two or more levers, as usual, such lever having a fulcrum with a universal or double-action joint, and being worked by a double tappet on the driving shaft. *Patent completed.*

742. W. REAY. *An improved machine for amalgamating minerals and other metalliferous and metallurgical products and substances.* Dated March 19, 1863.

This invention is not described apart from the drawings. *Patent completed.*

743. R. COUCHMAN. *Improvements in articles or means for supporting or carrying ladies' parasols, bags, or other articles or appendages.* Dated March 20, 1863.

This invention consists in attaching to a lady's waist band, belt, or other suitable part of a lady's dress, an instrument so formed as to be suitable for receiving and holding the handle of a parasol, bag, or other article or appendage. For this purpose a simple form of instrument of this character may be constructed of wire, or from stamped metal, bent into such a form that one part thereof may pass over and be secured to a lady's belt or waistband, or be otherwise secured to part of the dress. From the front of the instrument arms project capable of springing together in order to hold and support the handle or other part of a parasol, bag, or other article when inserted therein, the space between the two arms being secured by means of a chain, ring, spring, catch, or otherwise. Instruments of like character for this purpose may be formed of cast metal, or of other suitable materials. *Patent abandoned.*

744. A. BARCLAY and A. MORTON. *Improvements in certain apparatus for injecting and ejecting fluids.* Dated March 20, 1863.

This invention relates to an apparatus whereby the ejection of water or other fluid causes the injection of water or other fluid without the intervention of pumps or other moving machinery. One mode in which this invention may be carried out consists in the placing of two flat or curved discs parallel or nearly so, and near to each other, but with a small space between. One of these discs, with a pipe or pipes attached, communicates with the actuating fluid by an orifice through the centre of the disc; whilst the other disc, with its pipe or pipes attached, communicates with the water or other fluid to be actuated upon by an orifice at some distance from its centre. This orifice may be either a ring of holes, slits, or openings of any similar kind. When steam or other actuating fluid is admitted through the orifice in the centre of the former disc, it impinges against the solid centre of the latter disc, and radiates in a thin sheet between the two towards their circumference. This motion causes the fluid now acted upon to be drawn or forced through the ring of holes, slits, or other openings, and carried along with the actuating fluid for the purpose of being injected or ejected. *Patent abandoned.*

745. J. and T. A. NIELD. *Improvements in core barrels.* Dated March 20, 1863.

This invention relates to core barrels for casting pipes, columns, cylinders, or other artices of cast iron or other metals. The core barrel may be made of any desired number of segments or curved plates, joined together by hinges, and at the ends and middle of each segment there is a curved projection or lug. Through the interior of the barrel there is a shaft, having fixed to it a number of cams corresponding with and working in juxtaposition with the lugs or projections on the segments. When the shaft is turned until the largest radius of each cam is in contact with its corresponding lug, the core barrel is expanded to its largest diameter; but when the shaft is turned, so that the cams are between the curved projections or lug, the barrel is allowed to collapse. At each end of the barrel there is a plate which covers the cams, through which plate and one or more of the lugs a pin is inserted for the purpose of maintaining the barrel in its expanded condition. *Patent completed.*

746. R. A. BROOMAN. *Improvements in machinery for beating and drying wool, and other textile and filamentous substances.* (A communication.) Dated March 20, 1863.

This invention is not described apart from the drawings. *Patent completed.*

747. V. HOUGHTON. *Improvements in lamps and lamp wicks.* (A communication.) Dated March 20, 1863.

We cannot here give space to the details of this invention. *Patent abandoned.*

748. G. WILSON. *An improvement in the manufacture of springs.* Dated March 20, 1863.

For the purposes of this invention, the heated end of a bar of steel is made to enter a cross-head, moved forward by steam or hydraulic pressure, or other means, the cross-head being shaped internally so as to bend the end of the bar of steel into a circle of the required size, the other end of the bar of steel being fixed in guides or slides, or by other means. *Patent abandoned.*

749. G. COLES, J. A. JACQUES, and J. A. FANSHAWE. *Improvements in machinery or apparatus for washing or wringing clothes or fabrics.* Dated March 20, 1863.

This invention relates to that class of machines in which the clothes are passed between rollers for the purpose of squeezing or forcing out the water that the clothes or fabrics take up from the vessel to which the washing, squeezing, or swinging apparatus may be adapted. The improvements consist—1, in a novel mode of constructing the squeezing rollers; 2, to an improved mode of mounting them. The first improvement consists in making one or both of the squeezing rollers cellular, and of some suitable elastic material. The cells of the rollers will therefore take up a certain quantity of suds or liquid, and when the elastic rollers are compressed by passing the clothes or fabrics between them, the liquid, being incompressible, will be forced or squirted through the fabric, and in so doing will effectually remove any dirt that may adhere thereto. When the machine is to be used for washing alone, two elastic rollers will be sufficient; but if the machine is to be a combined washing and wringing machine, then an additional smooth elastic upper roller must be employed. *Patent completed.*

750. C. PRYSE and D. KIRKWOOD. *Improvements in breech-loading firearms, part of which improvements are also applicable to other descriptions of firearms.* Dated March 20, 1863.

This invention is carried out as follows:—At the breech end of the barrel a charging chamber is formed, at the rear end of which, inside, a projection is made. This chamber may be constructed to close by means of a hinged cap at either side or above or below; by preference the top. The cap is raised by means of a lever working on a pin passing through the cap, and upon which pin is fixed a cam or eccentric turning with the action of the lever. Upon the inside of the cap is fixed a plug or breech piece, intended to force the cartridge into the barrel, so that, when charged, the cap down, and the lever turned into a line parallel with the barrel, the longer axis of the cam or eccentric is also in a line with the barrel, and a rise or projection, which is formed upon its lower part, being brought under the projection in the rear of the charging chamber, the whole of the parts are thereby securely locked together. For the purpose of more firmly packing the breech piece and avoiding windage or escape of gas, the end of the plug may, if necessary, be furnished with washers, which may be removed and replaced with new ones whenever requisite; or the chamber being formed slightly taper at the rear, and the cam of corresponding form, the projections on the cam and in the chamber may be dispensed with. The plug or breech piece being formed into the barrel is of itself sufficient security against the cap blowing up. Again, to effect a partial locking operation, an incline may be cut upon the cam, and a corresponding one in the rear of the charging chamber, which, acting after the manner of a screw, affords an additional security in case the lever be neglected. The lever may be prolonged in the direction of the cock or hammer, so as to prevent the cocking of the arm whilst in an insecure condition. Secondly, the invention comprises certain improvements in the nipple, applicable also to other firearms than breech-loaders. *Patent completed.*

751. J. BRIGHAM and R. BICKERTON. *Improvements in reaping and mowing machines.* Dated March 20, 1863.

The patentee claims—1, the system or mode of arranging and constructing reaping or mowing machines, with a cast-iron main frame formed in a single piece, and suitably shaped to receive the bearings of the several shafts and other details of the machine; 2, the general arrangement and construction of the mechanical details for adjusting the height of the finger bar and cutters by means of a simple movement of a hand lever, so as to cause the machine to cut the crop either close to or further away from the ground, as may be found desirable, as described. *Patent completed.*

752. F. DE WYLDE. *Improvements in the manufacture of cement from gypsum.* Dated March 20, 1863.

The patentee claims the manufacture of cement from gypsum with the solution of silicate and carbonate of potash, in the proportions and under the conditions specified. *Patent completed.*

753. J. M. EVANS and W. F. GRIFFITHS. *Improved means for ventilating mines.* Dated March 21, 1863.

This invention has for its object the ventilation of mines in an efficient manner by means of steam and heated air, without the use of open furnaces or fires. The inventors erect, contiguous to the upper part of the upcast shaft a tower or structure open at the top (except as hereafter described), and they lead from the lower part of this tower or structure a hot-air tube, or hot-air tubes, in communication with a fire-clay pipe or channel formed at one or at each side of the furnace in the form of a channel or hollow part of the brickwork of the furnace of a steam boiler, the air in this pipe being thus heated in the furnace, and supplying the interior of the tower or structure at the lower part; and they prefer to carry a steam pipe from the top of the said steam boiler into an upper joint of the interior of the said tower or structure, at the end of which steam pipe they provide a steam box having a ring or jet pipes projecting upwards therefrom. Above this steam box they also prefer o have attached at or near the top of the tower or structure an inverted cone or dome, to the end that a quick and adjusted draught may be obtained. The tower or structure containing the inverted cone or dome may be widened out, so as to have greater interior area in the upper part thereof, and the inverted cone or dome may be raised or lowered for adjusting the draught. The bottom of the tower aforesaid they make inclining to the centre, so as to be able to form a drain to carry off any condensed water that may fall. For mines having one shaft only the above arrangement may be connected with the upcast side of the lattice. *Patent abandoned.*

754. F. and A. ROBERTS. *Improvements in agricultural implements, and in apparatus for working the same.* Dated March 21, 1863.

This invention comprises various improvements in agricultural implements, and in apparatus for working the same, being more particularly designed for application in the cultivating system wherein two reversed sets of ploughs or other agricultural implements are drawn backwards and forwards between a steam engine, and a stationary pulley or anchor, or two steam engines or two anchors, some of the improvements being also applicable otherwise. *Patent completed.*

755. C. DE GROOTE. *Improvements in the construction of lamps with circular burners or wicks for the combustion of petroleum, schist, and other volatile oils, parts of said improvements being applicable to gas burners, night lamps, and lamps burning spirits and animal oils.* Dated March 21, 1863.

This invention relates to lamps with circular wicks, known as Argand burners, and more particularly to lamps in which petroleum, schist, and other volatile oils are to be used, and consists in adapting to such lamps wire gauze guards, through which the air passes to support combustion of the flame of the lamp. *Patent abandoned.*

756. G. A. BIDDELL. *Improvements in locomotives, usually called "traction engines," to be used on common roads.* Dated March 21, 1863.

This invention consists in the application and use of a friction clutch or clutches, in combination with suitable driving and dinengaging gear. The piston rod of the steam cylinder gives motion to the main or crank shaft, on which the friction clutches are, by preference, placed, although they may be placed on an intermediate shaft, one part having a sliding motion thereon, but always turning with it, whilst the other part which carries a toothed wheel is capable of turning thereon freely when the two friction clutches are not pressed together. On the main or crank shaft is a fly-wheel. The toothed wheel carried by the friction clutches gives motion to another toothed wheel fixed on a second shaft, on which second shaft are two toothed pinions, which turn with but can slide on that shaft. These pinions are coupled together by double-crank connecting rods and forked levers, or other suitable contrivance, in such manner that, when one is moved out of gear with its wheel, the other is moved into gear with its wheel. The crank by which these two pinions are slid is on a separate shaft, having a lever handle thereon, by which it can be turned in one or other direction at pleasure, and, by the interposed mechanism, slide the two pinions. One of these toothed pinions works in the teeth of an internal wheel, whilst the other works in the teeth at the periphery of a wheel of lesser diameter, but both these wheels are fixed on the same shaft. There are also two toothed pinions on this axle or shaft, which rotate with, but are capable of sliding on, the ends of this shaft or axle, so that either or both of such pinions may be in or out of gear with spur wheels carried by the two main road wheels. *Patent completed.*

757. E. HARTLEY, J. CLEGG, and T. and J. MELLODEW. *Improvements in looms for weaving.* Dated March 21, 1863.

This invention relates—1, to making the shed in looms. For this purpose, the patentees employ two endless chains or equivalent apparatus, the one acting upon a lever so as to depress it, and the other so as to raise it. These chains are both placed on the same side of the centre motion on which the said lever turns, and act upon the same roller carried thereby. 2, The invention relates to that construction of picking motion of looms in which the lever which is struck by the tappet is moveable, and consists in the employment of an endless chain of tappets or equivalent apparatus acting upon the said lever, whereby the patentees are enabled to vary the number of following picks at each side of the loom at pleasure. *Patent completed.*

758. J. M. HETHERINGTON. *Improvements in machinery or apparatus for combing cotton and other fibrous materials.* Dated March 21, 1863.

This invention refers to that description of machine for combing cotton and other fibrous materials known as Hielman's, and consists in a method of feeding the material to the usual nippers thereof. In the above-named description of machine, this feeding is effected by a pair of rollers, which, by their occasional revolution, convey forward the material, so as to afford a given length to the aforesaid nippers, which then present it to the revolving comb working in conjunction with other rollers, so as to afford a combing of both ends thereof. This invention consists in the removal of the said feeding rollers, and in substituting therefor a reciprocating apparatus, which thrusts the material forward by a rectilineal action, as distinguished from that of rotary surfaces, by which means the patentee is enabled to allow that point which acts upon the material to approach nearer to the usual nippers, and therefore to operate upon fibrous material of comparatively short staple. *Patent completed.*

759. F. APPLEGATE. *Apparatus for making certain indications in railway carriages.* Dated March 21, 1863.

This apparatus consists of a disc mounted on an axis, which disc is caused to rotate by means of a tangent screw, working on a wheel of such diameter as may be necessary in proportion to the diameter of the disc. On the sides of the disc are painted or otherwise indicated the names of the several stations on the line of rails, which names occupy a radial position. *Patent abandoned.*

760. F. APPLEGATE. *Improvements in time indicators.* Dated March 21, 1863.

This invention consists in the application of revolving discs on which to represent the progress of time, instead of hands, as in a clock or watch, such discs being so combined, arranged, and prepared as to show the time as used and indicated in railway time tables, that is to say, by representing the numeral or numerals corresponding with the hour, and also a numeral or numerals indicating the minutes:—for example, 4 hours 20 minutes, instead of by the ordinary clock or watch face and hands. *Patent abandoned.*

761. W. CLARK. *Improvements in the separation or obtaining of ammonia from azoted matters in the preparation of manure.* (A communication.) Dated March 21, 1863.

This invention consists—1, in causing azoted matters to be filtered through suitable substances for retaining and settling the ammonical products in the azoted matters, yet permitting the escape of the liquids after they have been partly or entirely deprived of the azoted compounds contained therein; 2, in retaining and settling or depositing partly or entirely the ammoniacal compounds of azoted matters by means of phosphoric acid in the free state, or partly combined with the bases, so as to produce therefrom acid phosphates, and a salt of magnesia; or more simply by the aid of acid phosphate of magnesia, so as to produce as filtration takes place ammoniaco-magnesian phosphate insoluble in water; 3, the patentee states he may also proceed by precipitation, pouring phosphoric acid or acid phosphates and a salt of magnesia on to the ammoniacal matters; or, acid phosphates of magnesia may be used in order to produce ammoniacal magnesian phosphate above indicated, and allowing it after standing a sufficient time to be separated from the liquid part, which is now of no value on account of its being deprived of the ammoniacal compounds it contained. *Patent completed.*

762. H. HANCOCK. *A new combined range for making gas, cooking by gas, and lighting, especially applicable to ships.* Dated March 23, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

763. J. W. H. and E. J. ROTHWELL. *Improvements in heating the feed water of steam boilers.* Dated March 23, 1863.

This invention consists in placing in the flue or flues, and as close to the bridge of the furnace as practicable, a coil or zig-zag arrangement of pipes, through which the feed water is passed by means of any suitable mechanism. The water is conveyed to the coil or zig-zag arrangement of pipes by a pipe passing either through the ashpit, or from the other end of the boiler to that containing the furnace, and the outlet pipe for conveying the water into the boiler from the said coil or zig-zag arrangement of pipes is passed either through the ashpit, or along the flue in the opposite direction to any convenient part of the boiler. The inventors also pass the water from the coil or zig-zag through a pipe in the side of the flue direct into the boiler. *Patent abandoned.*

764. W. JOHNSTON. *Improvements in apparatus for lighting and heating.* Dated March 23, 1863.

This invention is not described apart from the drawings. *Patent completed.*

765. T. G. GRANT. *Improvements in ovens and apparatus for heating the same.* Dated March 23, 1863.

For the purposes of this invention, an oven is constructed of sheet iron rivetted together, and it is formed with horizontal shelves on the interior, which it is preferred should be of open work, and the front is covered with doors, preferring that there should be doors opposite the space between two shelves, in order that the meat or other food placed in such space may be got at without opening the front of the oven to a greater extent. An oven, such as above described, is fixed within a chamber or case, also made of sheet iron plates rivetted together. The case is of such dimensions as to leave a space at the back and at the two ends, and also over the top and under the bottom of the oven, but the front of the oven is not enclosed by the case. Below the oven is a fireplace, which is arranged in such a manner that the heat and products of combustion pass off between the oven and the chamber laterally, and towards the back, and then rise up to the upper parts of the chamber. It will thus be seen that the oven is contained in a highly heated chamber. At the upper part of this case or chamber is a chimney having a valve or slide to regulate the passage away of the products of combustion. At the upper part of the oven there are tubular passages with valves by which steam and vapours arising from the food which is being cooked may pass from the oven into the outer atmosphere. Provision is made in the outer casing for cleansing the interior of this chamber, and the exterior of the oven, doors being used for this purpose with valves to regulate the admission of air into the chamber by which the heat of the oven can be regulated. *Patent completed.*

766. J. EYLES. *Improvements in cheffonier bedsteads.* Dated March 23, 1863.

This invention consists in so arranging and fitting cheffonier bedsteads, as to contain and present for use all the fittings and utensils necessary for a bedroom. The inventor makes the greater part of the cheffonier to contain a turn-up bedstead, which is enclosed by single or double doors in the front of the cheffonier. The bedstead consists of a suitable frame and sacking, or other suitable bottom, with hinged legs to fall down to support the bed bottom from the floor. This bedstead, as before mentioned, occupies the greater part of the length of the cheffonier, while the other part is occupied with trays or shelves, and is furnished with a door at the end of the cheffonier by which access is had to the utensils contained. The upper tray or shelf is furnished and fitted suitably for washing, a washhand basin being inserted while the ewer may stand on a lower shelf, or it may be placed in the basin as usual, if the height above admits of it. He fits a tray or shelf below so as to slide, whereby it may be removed from below and placed above the basin itself, and form a table on which a looking-glass may be placed; or the looking-glass may be permanently mounted on this shifting shelf which at the same time forms a dressing-table. *Patent abandoned.*

767. W. CLARK. *Improvements in agricultural apparatus.* (A communication.) Dated March 23, 1863.

This invention relates to an improved agricultural apparatus to be used—1, for destroying field mice and all kinds of insects hidden in the ground, as also noxious weeds and vegetation, such as couch, chickweed, crowsfoot and others injurious to agriculture; 2, for scarifying the ground to a depth of 5 in. or more, according to its nature; 3, for harrowing the ground in order to clean it; 4, for crushing or breaking the clods; 5, for ploughing it with a large ploughshare; 6, for ploughing light sandy soils with two, three, or four small shares; 7, for trenching or draining land simultaneously with the ploughing, that is, to form channels of 3 in. or more in depth in the bottom of each furrow for carrying off the water. These channels, which are made when ploughing by the scarifying tines, are immediately covered up by the soil turned over by the mould-board of the plough. 8, It may lastly be used for preparing the ground simultaneously with the ploughing for planting colza. This improved apparatus consists of an iron frame mounted on two hind wheels, and with a fore-carriage also provided with a pair of wheels. The frame is supported by the hind axle, on which are mounted sliding bearings, carrying the travelling wheels; the wheels are regulated in height by means of jointed levers in order that the implement shall penetrate more or less into the ground. This arrangement consists of 3 parts: 1, the lever arm; 2, a ratchet-wheel; 3, a rod which is attached to the bearings carrying the axle. The [illegible] and rod are geared with the ratchet by means of [illegible] mounted on the lever. By this arrangement [illegible] the implements may be adjusted at any requi[illegible]

the ground without stopping the horses. A steering apparatus is placed in the centre of the frame, consisting of a large and small bar, which serves to guide the fore-carriage and frame in any desired direction, especially on hilly or uneven ground, in order to prevent its overturning. The fore-carriage is attached to the framing by the cross bar of the steering apparatus, and by tie rods connected to same, which may or may not be curved at their extremities; the other ends of the said tie rods are fixed to the draw bar. Sockets of the number of 23 are cast on the frame for fixing the various cultivating implements, letters being also applied on the frame indicating the position of each in their respective sockets. By the aid of the several parts above referred to, the inventor may regulate the depth to which the several implements enter the ground, 7 in. being the usual maximum depth, which may be still further increased another 5 in. by raising the wheels with the arrangement of levers and pawls above described. *Patent completed.*

768. H. Cook. *Improvements in the arrangement and construction of apparatus for transmitting electric currents and signals for telegraphic purposes.* (A communication.) Dated March 24, 1863.

An extension of time for filing the final specification of this invention having been petitioned for, the documents relating to the invention cannot at present be seen.

769. J. Reilly and W. Martin. *Improvements in lubricating horizontal shaftings and bearings of all descriptions.* Dated March 24, 1863.

This invention consists in forming the steps or pedestals of horizontal shafting with a recess or box to contain the oil or lubricating matter, so that as the shafting revolves, it will only t... up or use as much of the lubricating matter as is n...ssary for the purpose, and thus prevent the waste so gene...ally complained of. By the term bearings as named in the title, the patentees mean the bearing surfaces of the axles of railway wheels, and the axle boxes, and also the bearing surfaces of the shafts and pedestals of shafts for marine and stationary engines, and also the pedestals and bearing surfaces of all descriptions of horizontal shafting. *Patent completed.*

770. G. Davies. *Improvements in wrappers or papers for needles, and in machinery or apparatus for sticking needles therein.* (A communication.) Dated March 24, 1863.

This invention consists—1, of a strip of paper, or other suitable material, into which the needles are stuck and arranged separately from each other, the paper with its needles being permanently attached to a wrapper arranged for folding over and enclosing the needles. The object of the improved wrapper is to prevent that loss of needles which frequently takes place on removing them from or replacing them in ordinary wrappers. 2, This invention consists of certain mechanism for the sticking of uniform rows of needles in ridges formed on a continuous strip of paper, preparatory to the formation of the above mentioned wrappers. *Patent completed.*

771. S. Healey. *Improvements in the manufacture of zinc, and in the apparatus employed therein.* Dated March 24, 1863.

This invention consists in constructing the furnaces employed in the melting and annealing of zinc in close proximity to each other, so that the process of annealing may be effected by means of the waste heat escaping from the melting furnace. *Patent abandoned.*

772. H. Williams. *Improvements in machinery or apparatus for dressing slates.* Dated March 24, 1863.

According to this invention, it is proposed to employ a horizontal knife or knives working vertically, so as to receive a chopping motion. The knife or knives is or are carried by arms keyed on to a horizontal rocking shaft, supported in bearings fixed to the main framing of the machine. A rapid rocking motion is imparted to this shaft by means of a revolving crank pin carried on the end of the main driving shaft, and working in a slotted lever-arm keyed to the rocking shaft, or by means of a connecting rod worked by an eccentric. The driving shaft is supported on suitable bearings on the main framing, and is provided with the usual fast and loose driving pulleys. The machine is fitted with the usual gauge and travel. *Patent abandoned.*

773. A., J., and J. Topham. *Improvements in the manufacture of ornamental twist lace, and in machinery used therein.* Dated March 24, 1863.

According to the present invention, the patentees lead the bobbin threads sideways by means of warp threads, or threads worked like warp threads, which they call guiding threads; they act together with the ordinary points as they rise, and, when in the working of the machine a portion of the work is arrived at where some of the bobbin threads require to traverse sideways, the movement is effected by these guiding threads acting in such a manner as to cause the bobbin threads to be taken by the points up to the position in the work in which they are required, so that the tissue and the bobbin threads do not have to be moved afterwards as when drag threads are used. *Patent completed.*

774. J. Kirkham. *Improvements in the manufacture of iron and steel.* Dated March 24, 1863.

The object of this invention is to facilitate the conversion of granulated iron ore, obtainable in large quantities from the district of Taranaki, New Zealand, into iron and steel. The difficulty hitherto experienced in the smelting of this granulated ore or sand has been that the blast of a smelting furnace would disperse it, and that it was, therefore, necessary to employ saggers or pots for containing it while submitted to the smelting operation. The cost, however, of these pots prevented the economic use of the ore. Now, in order to effect the smelting of this pure ore of iron, the inventor first melts a portion of pig iron in a cupola furnace, or otherwise obtains fluid iron. This fluid metal he runs into what he terms a mixing furnace, and then applies thereto a suitable quantity of the Taranaki ore, stirring the same well so as to ensure a thorough mixing. The hot metal, acting as a solvent, will take up into combination the granulated ore. A portion of this mixture—say one-half—he now discharges into a puddling furnace, and puddles it in the ordinary manner, modifying the treatment according to the product required to be obtained. The remainder of the iron he returns to the cupola furnace to be reheated in order to render it fit to receive a second dose of the Taranaki or granular iron ore; he then proceeds with the operations as described. *Patent abandoned.*

775. A. J. Cooke. *Improvements in portable "hooka" pipes.* Dated March 24, 1863.

This invention consists in certain improvements in the construction of "hooka" pipes, whereby they are rendered capable of being carried in the pocket while being smoked, the tube only being visible. The inventor proposes to employ a cylindrical flat or oval-shaped vessel of metal or glass, the upper part of which is to be provided with a cap or stopper, through which the stem of the pipe bowl descends into the liquid in the vessel. The short leg of an inverted syphon is fixed in the interior of the vessel in such position as to be above the level of the liquid; the long end protrudes through the top of the vessel, and to this end the flexible tube and mouthpiece are attached. At the bend of the syphon a bulb is formed to receive the narcotic oil resulting from the tobacco. When required for outdoor use, the apparatus may be placed in a case or box of thin metal, having apertures at the top for the admission of air and escape of the smoke, and through one of which apertures the flexible tube is passed, thus ensuring perfect safety to the smoker. *Patent abandoned.*

776. J. White. *Improvements in protecting the surface of the iron and steel of ships and all other structures, except that of cables, tanks, and boilers, while in contact with water, from decay.* Dated March 25, 1863.

For protecting the surface of the iron and steel of ships' bottoms and other structures (except that of cables, tanks, and boilers) while in contact with water, from decay, the inventor fixes on the surface of the iron or steel zinc or aluminium equal to at least 1-16th part of the area of the surface of the iron and steel by means of iron or steel screws, rivets, or nails, taking care that the points of contact of the iron or steel and of the zinc or aluminium respectively are clean when they are fixed together, and that they are fixed in close contact. For preventing or abating, and for facilitating the removal of, foulness of ships' bottoms, and for giving a capacity of increased speed to ships, he covers the surface of the ships' bottoms while dry, by means of a plasterer's trowel or other implement, with a composition made by melting and mixing together equal parts of fat and oil, or about equal parts of fat, oil, and white lead, or one part of fat, two of oil, and three of powdered quick lime, and from time to time, when necessary, having scraped off the foulness, if any, from the ships' bottoms while dry or while afloat, he covers the ships' bottoms, while dry or afloat, again with any one of the said compositions, using for that purpose, when necessary, a diving apparatus, and rubbing on the composition with the hand and using a plasterer's trowel or other implement for spreading it. *Patent abandoned.*

777. M. Phillips. *Improvements in the manufacture of iron or other metallic rod or wire, and in the machinery or apparatus employed in such manufacture.* Dated March 25, 1863.

In carrying out this invention, the inventor takes a cylinder or pipe from 4 ft. to 5 ft. long, bored internally to 2½ in. diameter, or thereabouts, in which cylinder is a solid plunger or piston, worked either by hydraulic pressure, or by means of a crank or otherwise from any suitable machinery. At the opposite end of the cylinder to that which the piston enters a cap of hard cast iron or steel, 6 in. to 8 in. long, is fastened to the cylinder, on the one side by a strong hinge, and on the other side by a hasp, or in any other suitable way, so that the end of the cylinder may at once and with ease be laid open at each back stroke of the piston for inserting the heated billet of metal, and covered with the cap again for the forward stroke of the plunger. The cap is bored longitudinally, the hole tapering from 2½ in., where it fits against the bore of cylinder, to 1 in. at the other end. At the end of the cap a cast steel block or point is screwed in, bored in the same way and tapering, from an inch, to the size required for the rod or wire. The point can be changed in an instant when it is required to change the size of rod. The hot billet comes from the falling furnace out to the required length, in the same way as for the guide rolls, and is pushed into the cylinder, the plunger being then at the other end for the commencement of the stroke. The cap is at once closed and fastens with the hasp of its own accord. The forward stroke of the plunger forces the billet through the taper bore of the cap and steel point; it comes out at the other end a rod in every way better finished than a rolled rod. Close by the point must work a small light pair of shears, worked in the usual way for cutting the rods into the required lengths. At the end of the stroke the rod, if not for wire, must be cut off as close to the point as possible, the cap again opened, and a second billet put in, which not only pushes out the small portion of the first billet remaining in the taper of the cap, but from the great pressure used welds with it and forms one continuous rod. *Patent abandoned.*

778. J. Leach and J. Anderson. *Certain improvements in machinery or apparatus for preparing and spinning cotton and other fibrous substances.* Dated March 25, 1863.

This invention relates to all descriptions of machinery for preparing and spinning cotton and other fibrous substances, wherein drawing rollers are employed; and the arrangements consist in the employment and use of front bottom rollers having smooth surfaces or peripheries, in contradistinction to such surfaces being fluted, grooved, roughened, or rendered otherwise uneven, such fluted or uneven surfaces having been regularly employed and considered necessary hitherto; whereas, by the use of front bottom rollers made with smooth surfaces or peripheries, a considerable improvement is effected in the quality of the yarn, the leather coloured top rollers are not injured as by fluted rollers, and the hold upon the fibres or yarn is not diminished. *Patent completed.*

779. J. H. Worrall. *Certain improvements in the method of producing surfaces in imitation of woods, and in printing therefrom.* Dated March 25, 1863.

This invention is designed for the purpose of obtaining fac-simile impressions or representations of woods, by so treating the surface of the wood as to render the natural grain thereof available for transferring or imprinting the pattern upon paper, or other material, the pattern so produced being applicable to imitation graining, paper-hangings, oil-cloths, figuring and embossing leather and textile fabrics, and to other ornamental purposes. The improvements consist in an improved method of obtaining such impressions from the natural surfaces of woods on paper, copper, zinc, or stone, and in transferring the patterns therefrom, and printing them upon surfaces such as paint, wood, stone, metallic surfaces, or textile fabrics, so as to represent the natural grain or appearance of the wood. *Patent completed.*

780. G. Stuart. *Improvements in bleaching jute fibre.* Dated March 25, 1863.

The patentee claims the bleaching of jute fibre by immersing it twice or oftener in a solution of a chloride, each such immersion being followed by an immersion in dilute sulphuric acid. *Patent completed.*

781. C. Monson. *An improved gravitation engine.* Dated March 25, 1863.

In carrying out this invention, the patentee employs two vessels of similar construction connected together by a pipe or tube, and exhausts the air therefrom. He then partially fills one of the said vessels with water, or other fluid, and generates steam within it, which steam will by its pressure upon the surface of the fluid cause it to flow from the vessel so filled with fluid through the connecting pipe or tube into the second vessel; and by employing the weight of the fluid caused by such change from vessel to vessel, or from the second back to the first, he obtains a power which may be used for the various purposes for which motive power is required. *Patent completed.*

782. R. Armitage and C. Senior. *Improvements in means or apparatus for stretching fabrics.* Dated March 25, 1863.

This invention relates to machinery employed in the finishing of textile or other fabrics, known as tentering and drying, in which process it is necessary to stretch or expand the fabrics; and the object of the first part of the invention is to produce or effect uniformity in the stretch or expansion, also any degree or amount as may be required thereon. For this purpose, the patentees apply a roller or rollers at the feeding end of the machine for retarding or holding back the fabrics as they are fed thereto. Such roller or rollers is or are driven at a less or lower surface speed than the rollers and chains or other conducting means by which the fabrics are travelled through the machine, and are capable of more or less speed being readily given thereto, according to the amount of stretch or expansion required. The driving pulley fits loose on the boss of a worm wheel, which is fixed on the retarding roller, but has a worm mounted thereon which gears with the wheel, and forms a clutch or driver thereto. A star wheel is mounted on or geared with the worm, and receives motion or is operated by projecting pins fixed in the orbit of the star wheel, or in its line of travel, thus producing a differential motion. The number of pins to operate the star wheel in each revolution may be varied according to the speed required to be given to the roller or rollers. The second part of the invention consists in applying fingers or levers to press the fabrics on to the tenter hooks or teeth, motion being given thereto by tappets or cams. The third part consists in having the rollers which are employed in conducting the fabric through stretching machines made in two or more parts, telescopically, and arranging them in the machine alternately with thick end and small end to each other, so as to maintain or produce equal lengths of the lists or edges of the fabrics. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 15, 1863.

1491. W. W. Box, Birmingham, engineer. Improvements in fire bars for the boilers of locomotive and other engines, and for fire boxes and furnaces generally.

Dated July 11, 1863.

1739. H. Greaves, Abingdon-street, civil engineer. Improvements in the construction of railways and tramways.

Dated September 11, 1863.

2241. L. Meyer, 36, Rue de Marseille, Paris, glass maker. Improved means of, and apparatus for, employing vapours, gases, and the heat derived from combustible matters.

Dated September 18, 1863.

2300. H. C. Huskinson, Manchester. Improvements in the manufacture of buttons.

Dated September 26, 1863.

2373. L. H. Norris, 6, Upper Bedford-place, Russell-square. Improvements in the manufacture of india rubber and gutta percha compounds. (A communication.)

Dated October 6, 1863.

2443. W., H., and T. Holgate, Accrington. Improvements in the manufacture of pickers used in weaving.

Dated October 7, 1863.

2449. D. Barr, Birmingham, house and estate agent. Improvements in apparatus for regulating and working window blinds.

Dated October 8, 1863.

2463. A. P. Charpentier, Palais Royal, Paris, France, watch manufacturer. Improvements in the manufacture of watches.

2467. W. Lorberg, 4, Wyld's-rents, Bermondsey, analytical chemist. Improvements in the manufacture of gas from tar.

2469. R. G. Watson, gentleman, and W. J. Kendall, mechanic. An improved walking-stick umbrella.

2471. J. Spencer, Doncaster, implement manufacturer. Improvements in machinery for separating different sizes of roots.

Dated October 9, 1863.

2477. G. Parry, Ebbw Vale Iron Works, Monmouth, furnace manager. Improvements in refining crude pig iron and in furnaces connected therewith.

2479. J. Mather, Crow Oaks, near Radcliffe, Lancaster, bleacher, dyer, and finisher. Improvements in friction or glazing calenders.

Dated October 10, 1863.

2485. J. Vaughan, Middlesborough, ironmaster. Improved apparatus for purifying waste gases from blast and other furnaces.

2487. J. Ruthardt and F. Thiele, Oxford-market, Oxford-street. Improvements in apparatus for purifying and increasing the illuminating power of gas.

2491. T. Hughes, Wolverhampton, tin plate worker. Improvements in the manufacture of lanthorns.

Dated October 12, 1863.

2493. P. R. Jackson, Rolling Mills, Salford, engineer. Improvements in the manufacture of hoops and tyres for railway wheels and other purposes, and in the machinery employed therein.

2495. J. G. Hartley, 11, Lawrence Pountney-lane, shipowner. Improvements in the construction of iron and wooden ships and other vessels.

2497. W. T. Bury, Regent Works, Sheffield, steel manufacturer. An improvement in vessels or baths for containing heated metals and fluxes employed in the processes of hardening and tempering steel and steel articles.

2499. T. Gidlow, Heaton, coal proprietor. Certain improvements in bearings for axles for railway or other carriages.

2501. W. E. Gedge, 11, Wellington-street, Strand. Improvements in shears for cutting metals and other substances. (A communication.)

2503. R. Aitken, Cambridge-street, Pimlico, civil engineer. Improvements in the permanent way of railways.

2505. J. J. Anderton, St. James-street, Northampton, currier. Improvements in machinery for cutting and finishing the edges of the soles and heels and the bottoms of boots and shoes.

Dated October 13, 1863.

2507. G. Morgan, 3, Budge-row. An improved "sample" bag for postal and other purposes.

2511. T. C. Craven, Greenbush, New York. Improvements in cotton gins.

2513. J. Fowler, Leeds, engineer. Improvements in apparatus used for hauling agricultural implements.

Dated October 14, 1863.

2515. J. Rowley, Leeds. Improvements in apparatus for washing, scrubbing, scouring, bleaching, and discharging impurities or other matters from woven or other fibrous materials.

2517. E. P. Colquhoun and J. P. Ferris, 1, Lawrence Pountney-hill. Improvements in fire-bars for the furnaces of steam boilers, and the mode of mounting the same.

2519. J. Milton, manager, Paisley. Improvements in looms for weaving.

2521. O. E. Sonnenstein, Circus, Minories. Improvements in reflecting apparatus. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated October 14, 1863.

2522. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. An improved apparatus for cleaning ships' hulls. (A communication.)

Dated October 17, 1863.

2546. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in washing machines. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, October 27, 1863.

1480. J. Hopkinson. Fastening the ends of metal bands.

1481. W. N. Hutchinson. Apparatus for cleansing ships' bottoms and sides.

1497. T. Petitjean. Glass.

1498. R. W. Gordon. Spinning flax.

1501. J. J. Shedlock. Valves for the passage of steam, gas, and fluids.

1508. J. Steele and W. Mason. Removing the bran or outer skin from wheat and other grain.

1509. A. J. Fraser. Apparatus applied to house and carriage window sashes for working and fastening thereof.

1511. J. C. Onions. Smith's and other bellows.

1512. R. A. Brooman. Protecting or preserving the silvering or quicking on glass. (A communication.)

1514. J. Banwell. Machine for collecting and elevating into a waggon, hay, corn, or other agricultural produce.

1516. J. Newnam. Boiling in vacuo at low temperature.

1525. J. L. Ganne. Toy-pistols.

1531. E. Gossiaux. Machine for making bolts, rivets, &c.

1537. A. Morel. Combing wool, &c.

1538. A. Morel. Traction engines.

1545. D. D. Kyle. Baths.

1551. J. L. Clarke. Turning over the leaves of music.

1555. W. L. and T. Winans. Steam vessels.

1556. W. L. and T. Winans. Couplings for propelling shafts of ships or vessels.

1557. W. L. and T. Winans. Propellers.

1558. W. L. and T. Winans. Propellers.

1563. A. Twaddell. Sizing or preparing warps.

1565. W. Snell. Arrow-shaped projectiles and guns. (A communication.)

1568. W. Rowan. Pistons.

1570. W. L. and T. Winans. Adapting propellers for propelling ships or vessels.

1571. W. L. and T. Winans. Propellers for propelling ocean steam vessels.

1572. W. L. and T. Winans. Engines for actuating the propelling shafts of steam vessels.

1573. W. E. Newton. Printing machinery. (A communication.)

1578. W. W. Sleigh. Obtaining motive power.

1581. R. A. Brooman. Breech-loading arms. (A communication.)

1582. W. L. and T. Winans. Steam boilers.

1584. W. L. and T. Winans. Superheating steam in steam boilers.

1585. E. Brooks. Breech-loading firearms.

1589. S. Knowles and R. Hayward. Plaiting and measuring woven fabrics.

1603. W. Kirrage. A new and improved cloth for floors, roofs, walls, tanks, and other linings.

1608. T. Tulpin. Stretching and drying fabrics. (A communication.)

1609. W. Clark. Apparatus for aërating liquids. (A communication.)

1620. W. Andrews. Insulating electric telegraph wires.

1631. S. Cole. Clasps or fastenings for securing brooches, solitaires, and other dress ornaments.

1646. R. A. Brooman. Protecting metals and metallic articles from oxidation, and for coating slate, bricks, pottery, and ceramic ware. (A communicaton.)

1647. A. A. Croll. Purification of gas for illumination.

1656. C. Baulch. Boots and shoes.

1681. C. Schiele. Turbines.

1720. A. R. Johnston. Portable fence for sheep and cattle pens, or for other enclosures.

1721. M. A. F. Mennons. Preserving and protecting the silvering of mirrors. (A communication.)

1751. P. C. A. Jodocius. Fishing, and the apparatus or means to be employed therein. (A communication.)

1773. M. Henry. Figuring, ornamenting, and colouring fulled and felted fabrics and articles. (A communication.)

1816. F. Ayckbourn. Air and water beds, pillows, bolsters, and cushions.

1892. W. and J. Graham. Looms for weaving.

2008. C. Schiele. Fans, pumps, and machinery for propelling air fluids or other substances by centrifugal force.

2041. R. Baillie. Reefing or furling the sails of vessels, and in the apparatus to be employed therein.

2401. J. Mackay. Firearms, ordnance, and projectiles.

2413. J. E. F. Lüdeke and M. Fischer. Motive power.

2415. J. Tees. Packing for stuffing boxes and pistons.

2433. J. M. Guilmette. Substitute for whiting, pipeclay, and other analogous substances to be employed to produce a white coating or surface.

2459. J. Gibson. Cast-iron pit tubing.

2499. T. Gidlow. Bearings for axles for railway or other carriages.

2546. J. H. Johnson. Washing machines. (A communication.)

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed October 23, 1863.

1022. J. Cornes and J. C. Davis.
1033. J. P. and E. B. Nunn.
1050. M. Valkenhuyzen.
1056. W. Hudson and C. Oatlow.
1061. S. Crabtree.
1062. G. Hall and J. Wells.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 6, 1863.

RIVER STEAMERS.

THE danger and inconvenience arising from the enormous traffic which chokes City thoroughfares, and fills the great arteries of London with a nearly solid mass of cabs, waggons, omnibusses, and drays, have for some time attracted the attention and excited the fears of those best acquainted with the subject. These gentlemen dread that the time is not very distant, when all commercial transactions which depend on facilities for City transport, will be brought to an end. The apprehension is not ill-founded. Two principal thoroughfares are already blocked for eight hours out of the ten which constitute a working day; and the municipal executive, bestirring itself now, as it should have done months if not years ago, has established a novel code of City traffic regulations intended to mitigate the evil. For its provisions we must refer our readers to the daily papers. Whether it will have the proposed effect or not remains to be seen. The probability is, that it will for a time relieve our overcrowded streets; but the trade of London extends yearly; and the consequent annual increase in the number of passengers, and tons of merchandise, conveyed through its great thoroughfares is something enormous. Our railway companies gradually bring their lines nearer and nearer to one great centre, which they are ever approaching without reaching. Perhaps the centralization at which they aim is not desirable. Just now, however, the daily interchange of goods and passengers between the termini, instead of being diffused over a considerable region, is concentrated in the heart of the City—within a district, in fact, whose narrow streets, relics of the past, are already overburdened with the legitimate traffic due to the commercial transactions of the metropolis of which they form part. It is, therefore, difficult to believe that any bye-law, however admirable its provisions, can prove of permanent service. Nothing of the kind can strike at the root of the evil. Cheapside and Cornhill, Ludgate-street and the Poultry, are overcrowded, not because the traffic through them is too great, but because they are, from their small width, quite inadequate to supply a demand which has grown up with an age, whose progress has left them far behind. Bye-laws which propose to relieve these streets, principally operate by excluding certain vehicles during particular hours, to the great inconvenience of one portion of the public, without conferring any great benefit on the rest. In truth, the area of land available for roads is insufficient. We have been compelled already to burrow under London; and the extension of a principle, unobjectionable were it but admissible under the conditions, is matter for daily thought and calculation among engineers and capitalists. The Metropolitan Railway was, beyond a doubt, a step in the right direction; but though very convenient, it cannot be said to have in any way relieved the City of its all-but-unsupportable burden. Facilities for transport usually increase the demand which they are intended to supply; and, therefore, any scheme which proposes to aid intercommunication in the London district, must be on an immense scale, comprehensive in its provisions, and able to cope successfully with an enormous amount of work. The mere extension of metropolitan railways, admitting for the moment that engineers and contractors could successfully fight their battle with colossal sewers and ricketty foundations, cannot alone do much good. London requires more highway and by-way room, and every thoroughfare which can be pressed into the service with propriety should take its share in the work of transport.

In the Thames we have a highway no longer "silent," running east and west in the immediate neighbourhood of, if not in the closest proximity to, the most crowded commercial districts of London. Dividing the great city into two portions, its waters flow within a few hundred yards of those streets, choked and obstructed by a plethora of trade, which it is the paramount object of civic desire to relieve. The number of steamboats plying on this river, and the thousands of passengers who daily avail themselves of their services, are sufficient evidence that we have at our command an important auxiliary to any system of metropolitan railways, capable, under proper arrangements, of accommodating an enormous traffic. But, unfortunately, the Thames is not as popular as it should be. Certain redolent mists have hitherto hung about it, which the metropolitan main drainage will, we trust, soon remove for ever to the regions of Barking-creek or Crossness. Then the landing stages and stairs are hardly all that we could desire; while the approaches to them are so thoroughly bad, that we may regard the river as being, to a considerable extent, isolated from the City through which it flows. And lastly, there is no real accommodation for a considerable traffic in the shape of handsome and commodious river boats.

The magnificent inland waters of the Western Continent afford the only existing example of the full development of the system of river navigation. The floating palaces of the Ohio or the Mississippi would be equally out of place and unnecessary on such a river as the Thames. To vessels, 300 ft. long, and over 40 ft. out of the water, the Thames would be a mere dock. But the river boats of North America are worthy of imitation in one respect at least. The accommodation provided for passengers is everything that the most fastidious can desire. Roomy decks and immense saloons, are by no means essential to the comfort of those who travel by water, although they are concomitants to that desirable end, worth securing at a considerable price; and there is no difficulty whatever, or at least there should be none, in constructing steamboats intended to ply for hire on the Thames as the existing boats do, which should embrace every desirable feature of those vessels of which Brother Jonathan is so justly proud, yet without in any way exceeding the dimensions which experience has proved to be best adapted to the river on which their days would be spent. The wretched little steamers at present on the river, fail to supply any legitimate requirement. Their decks are dirty and crowded in the summer months; while, in winter, their dingy cabins are wisely eschewed by a discriminating public. A superior class of vessel would supply and augment an existing demand. Fitted with handsome saloons, erected on a deck, the full breadth of the boat over the sponsons—if the paddle wheel was retained—excellent accommodation would be provided for all classes in the most inclement weather; while the hull beneath, altered from the form which now obtains, but little increased in size, and no longer required for other purposes, would supply ample room for engines and boilers, powerful enough to secure a speed greater than anything heretofore attempted on the river. It is more than doubtful, however, that the best means of propulsion would be found in the paddle-wheel. In a situation where the greatest facilities for manœuvring are all but indispensable, we conceive that twin-screws could be employed with the greatest possible advantage. They would permit the adoption of a peculiarly formed hull admirably adapted to secure the stability which would be, to some extent, endangered by the out-board saloon deck; and as the depth of the water would allow of the use of screws, 6 ft. or 7 ft. in diameter, the engines would exert their power to much greater advantage through their agency, than by means of a paddle wheel only twice or thrice the size. If, however, it should be deemed expedient to retain the paddle in active service, provision should be made for steering the boat at each end, so that turning would be rendered unnecessary. This, however, involves a form of hull bad for speed, requiring much power to propel it, and altogether objectionable in various other ways. The saloons on deck, should be handsomely fitted up with plate glass, cushioned seats, &c., desiderata which entail very little expense.

In a few years, we trust to see the Thames Embankment scheme carried out as it should be; while the roadway, which it will form the substructure, will make a magnificent esplanade. The river, cleared of its noxious constituents, will most likely be accessible by a series of landings superior to anything which has gone before. A fleet of steamboats, at once commodious, clean, swift, cheap, and easily reached, without the necessity for invading questionable lanes and alleys, could not fail to be popular, more especially during the summer months. The Thames can scarcely be said to have hitherto taken its share of London traffic; and it is time that it began. Less than two centuries ago, its waters formed the main artery of communication through the City and Westminster. Some philosophers state that all things occur in a natural cycle of events. If such be the case, we confess we shall not be sorry to see Old Father Thames take part once more in any scheme which proposes to aid and facilitate that traffic which has become inseparable from the commercial wealth of the metropolis.

STEAM FIRE ENGINES.

IN another of our pages will be found the concluding portion of the Paper on "Steam Fire Engines and the recent Trials at the Crystal Palace," read by Mr. Roberts before the Society of Engineers, on the first Monday of last month. The discussion which followed we deem it best not to publish, as very little information, valuable in a general sense, was imputed by the speakers. The society is comparatively recent in its establishment, and its members are, for the most part, young men, who have scarcely yet learned that moderation strengthens argument, while personalities are out of place in scientific discussion. We must remember, however, that they represent the future generation of eminent engineers; and we feel little doubt that their proceedings will in future display that talent, good taste, and gentlemanly feeling, which have heretofore distinguished them. It is but just to say that the discussion was not confined to the members of the society. As to the merits of Mr. Roberts' Paper, our readers can judge

selves. It was got up with some care, and contains much useful information. We wish the discussion had been equally valuable.

The steam fire-engine question is, comparatively speaking, a thing of yesterday. Years ago, it is true, such machines had not only been proposed, but called into existence both here and in the United States; yet, until the trials of last year, brought the subject prominently before the world, very little was known of their requirements or relative efficiency as compared with the hand engines, on which we had before been entirely dependent for the safety of our streets and warehouses. Of the competition at Sydenham last summer, it is not our intention to speak. The subject has received sufficient ventilation. Even admitting every objection which can be urged against it, it yet served an admirable purpose, in that it demonstrated the facility with which thoroughly efficient machinery could be produced by those who devoted their attention to this department of mechanical construction. The three days' proceedings at the Crystal Palace were, in addition, the direct cause from which the publication of a considerable amount of valuable information resulted. The detached manner in which this was brought before the public seriously detracted from its usefulness; and the literature of the steam fire engine is meagre in the extreme. A lucid, comprehensive, and impartial treatise has yet to be written, and, if properly prepared, it cannot fail to prove serviceable.

In the steam fire engine, more particularly when intended for service on land, we have a machine which must satisfy many strictly exceptional requirements. In order that it may be useful and admirable in the fullest sense of the terms, it must not only be extremely light and portable, but of enormous strength as well. Intended to work under the most trying circumstances, and at seasons when the calmest pulses are accelerated, and the coolest heads lose their self-possession, it must be prepared for rough work and much knocking about. Nothing but first-class workmanship and materials can reconcile these incompatabilities. Ere long, we trust to see steel take the place which wrought iron now holds in the fire engine. It is already partially used, in the form of piston rods and crank shafts; and there is nothing to preclude its employment in the shape of boiler shells, and carriage frames. In cylinders and pumps, the use of homogeneous metal or malleable cast iron, would effect a very considerable reduction of weight, and positively add to their powers of endurance. The principle of annealing articles of cast iron required to sustain great strains, is better understood daily; and a steam cylinder or pump valve, one-fourth of an inch thick, so treated, is stronger than one of twice the weight left as it comes from the moulder's flask. By these means alone, we do not doubt that an important reduction might be effected in the weight of future engines; whilst improvement in the arrangement of the working parts, frames, and trusses, would permit a more equable distribution of the strains to which the machine is exposed, and materially add to its longevity.

The principles involved are simple enough. In their adaptation to the requirements of practice lies the difficulty. Steam gives out its useful effect equally well, whether a piston moves fast or slow, so long as economy of fuel is not an object of desire. Hence, if weight were not a consideration, the speed of the engine would be a matter of slight importance, and that velocity best adapted to the description of pumps employed, could be adopted without hesitation. In order to secure portability, however, in the highest degree, with a pressure kept within reasonable limits, quick-working engines are indispensable. This would, of course, entail no difficulty were the motion of water as manageable as that of steam. Unfortunately this is not the case; and, as a consequence, the steam fire engine, requires to be treated more as an hydraulic than as a steam machine. We are, therefore, inclined to prefer that principle of construction which permits a long stroke of the steam, and a short stroke of the water pistons. Such an arrangement is, perhaps, more likely to secure a high co-efficient of useful effect in proportion to the fuel burned and the weight of the machine, than any other. High-speed engines coupled directly to the pumps, are quite capable of doing good service, as our American friends have showed; but we imagine, with a very considerable and unnecessary waste of fuel. Were it not for the effects produced by wear, the rotary pump, as adopted in the "Manhattan," would seem to be best of any; and it is quite possible that this objection may not be found insurmountable. Notwithstanding a bad boiler, the admirable qualities of that machine, in everything concerning the engine and pump, were sufficiently manifest. We believe that excellent results would be obtained from a similar arrangement supplied with steam by a generator, say on Mr. Field's principle, of sufficient power. The rotary pump, however, is condemned for the present by those best acquainted with its capabilities; and it is, therefore, unnecessary to dwell further on its merits or demerits. That the best possible results have yet been obtained from the reciprocating pump is uncertain; and on the relative good qualities of those varieties employed by the three or four firms, in whose hands the manufacture of fire engines rests for the present, it is impossible to decide. We cannot separate the efficiency of the engine from that of the pump, as no diagrams have ever been taken from the cylinders of a steam fire engine. We fancy that the application of a Richards' indicator during the late trials would have produced some singular results, and afforded much valuable information. No careful or accurate estimate can possibly be made of the relative actual horse-power of the various machines exhibited. Everything stated on the subject is, in the absence of the necessary data, vague to a degree; and we are really as much in the dark as ever in all that concerns pumps and engines in their individuality.

As to boilers, that which supplies the greatest quantity of steam with the smallest consumption of fuel is not necessarily the best. The less coal burned, the less the wear and tear of tubes and fire-boxes, of course; but this is a secondary consideration, of little importance if weighed against the facility for getting up steam to high pressures in short spaces of time, and great capabilities for supplying it in quantities. Still a generator of the class required, may possess great steaming powers, and yet not make an excessive demand on the coal supply. It is a mistake to restrict the quantity of water too much. It is true that the number of gallons contained within a boiler, measure pretty accurately the proportionate time required for raising steam in different engines of nearly similar construction and dimensions. But spread it as thinly, and subdivide it as much as we may, the quantity of liquid measures the heating surface as well as the time. A few hundred additional cubic inches of water space, may frequently prove of the utmost advantage, while their presence cannot do harm. Too much importance is attached to the question of raising steam quickly. Only in cities and large towns will steam fire engines ever find a legitimate opening for the display of their powers. Gas can be had at a moderate price all over England—in every town almost which can boast a few thousand inhabitants; and it is certainly injudicious to endanger the durability of boilers which may be severely tried at almost a moment's notice, by a reduction in the quantity of water carried, when a gas jet may be kept burning in the fire-box night and day at a trifling expense. This system has been adopted at Watling-street station for some time past with great advantage; steam being usually maintained steadily at 5 lbs. on the square inch night and day. Messrs. Lee and Larned constructed some steam fire engines at one time which got 30 lbs. steam in 3½ min. Experience soon showed, however, that there was really no need for such expedition, and the time was extended to 6 min., and finally to 8 min., with a corresponding increase in the good qualities and general efficiency of the machine. Mr. Lee states that one of these 8 min. engines attended 170 fires, never being late but once, when the conflagration took place in close proximity to the engine-house; the steam being always raised from cold water while proceeding through the streets. Pressure is always unsteady with a limited water space, rising and falling with the most trifling variations in the state of the fire.

A great difference of opinion exists as to the relative merits of the horizontal and vertical arrangements of steam cylinders and pumps. We attach little importance to the question. It is, after all, merely a matter of constructive convenience, or the reverse. The great objection urged against the vertical system is, that it produces oscillation. This may be true; but engines on the horizontal plan are open to it as well—the vertical pitching motion is exchanged for one fore and aft; and as it is more difficult to scotch wheels effectually, than it is to run down clamping screws on the springs, we think the advocates of the vertical principle have slightly the advantage. Careful balancing will do much to remedy this evil in either case.

The importance of a steady speed, be it fast or slow, in any system of pumps intended to force water under great pressure, is well known. Our fire-engine builders do not appear to attach as much importance to it as they ought. A good governor would secure the desideratum far better than any manual attention. Serious injury is often done by an engine racing suddenly, on first opening the regulator, or on the bursting of a hose, or a failure in the water supply. The governor would prove an effectual remedy. If the centrifugal form is deemed objectionable, there are many others open to our adoption—a modification of Pitcher's governor, for instance, might probably be used with great advantage. These are, however, minor matters; and as we have good reason to be satisfied with the progress made in the last few years, we may safely leave this consideration, for the present, to those most interested. The necessity for a fly-wheel and crank-shaft is a more important question, on which great difference of opinion exists. We believe that its adoption simplifies the valve gear, gives steadiness to the motion of the engine, and permits a considerable reduction in the space occupied by the machinery—advantages not to be lightly sacrificed.

THE GREAT GUN QUESTION.

How to construct a gun of sufficient strength to fire heavy shot with heavy charges, and with accuracy at short or long ranges, is the artillery problem of the day. Strength of material and structure is the object eagerly sought by Ordnance authorities and projectors. Sundry and various are the devices to attain that end. Some contend that the coil system, in spite of the Armstrong failures, is the *ne plus ultra*; homogeneous iron is the *panacea* of the Whitworth school; cast steel is the hope of those who believe in Krupp; several varieties of built-up and strengthening systems, comprising the Blakely, the Lancaster, the Haddon, and the Lynall Thomas, have ardent advocates; the steel tube, cased in cast iron, is the latest invention, to which Parsons and Palisser are rival claimants. Among so many plans, no wonder the Ordnance Select Committee are puzzled which to choose. But plain cast iron is again holding up its head. The excellent quality of the old carron metal is remembered. Since the days of its celebrity, still further improvements in cast iron have been made, and a strong feeling prevails with some makers of cold blast pigs, that they can produce refined metal of a quality which will surpass all other kinds of iron, and be superior even to steel for heavy ordnance.

Strength of material, no doubt, is of the highest importance; but what has suddenly given to it so much prominence? It is the discovery recently made of the destructive effects of the forcing system of rifling. That vicious method of giving accuracy and range to guns, entails the necessity of an enormous addition to their strength and weight as well as to their cost.

Mr. Anderson, the talented superintendent of the gun factory at Woolwich, to whose mechanical skill Sir W. Armstrong is mainly indebted for the progressive improvements and perfection of workmanship in his guns, informs us that the systems of rifling hitherto employed "necessarily cause a straining on opposite sides of the gun tending to open it and break the metal."

It will be a curious, and not unprofitable study, to trace the action and the result of firing the Armstrong gun. I mean the polygroove rifled 110-pounder breech-loader, loaded with lead-coated cylinders—I don't know that the shunt is better or worse; but to avoid misapprehension, I explain that I refer to the former.

There is no windage; the projectile, being of greater diameter than the bore, offers immense resistance before it is forced through the rifling, so that the powder explodes with tremendous power; but so great is the friction, that the result is an initial velocity of 1,260 *ft. in a second*. The 68-pounder smooth-bore, with a windage of 5 per cent., gives the shot an initial velocity of 1,580 ft. in a second. The difference in velocity being 380 ft., there is a clear loss against the rifled Armstrong of 25 per cent. in propelling force. If we diminish the windage of the smooth-bore to 2 or 1 per cent. of the area of the section of the bore, we obtain an initial velocity of 1,800 to 2,000 ft. in a second, which makes a difference of 600 to 800 ft. in comparison with the performance of the Armstrong, and increases the loss of useful effect to 50 or 70 per cent. These figures speak volumes, they show at what an enormous loss, not only of money but of fighting power, the Government has adopted the Armstrong monopoly.

Here, then, we have the true solution of the immense strength required for rifled ordnance. Regarding the Armstrong gun as the actual embodiment of the worst points of a defective system of constructing artillery, we are naturally led to ask—What is the Armstrong system?

This the country, which has bought the system at the price of nearly three millions, have a right to know. The question is a complicated one; the solution not easy. It embraces many considerations; but, like other complicated questions, the best way of solving it is to show, by the exhaustive process, what the system is not.

It is not the coil principle, for that was invented and applied years previous to Sir William's first experiments in artillery. Before that period it was practically carried out by Professor Treadwell in America, and advocated by Mr. Longridge, C.E., and Captain Blakely, R.A., so that Sir William can lay claim to the initiative neither of conception or execution. It is not the breech-closing hollow screw, providing for the introduction of the charge through it at the rear of the gun, since that plan was one of the earliest adopted for breech-loaders. Nor is it making guns of wrought iron, or any particular method of building-up and strengthening the structure, for built-up wrought-iron guns were proposed and made centuries ago, and at intervals since then.* As a proof that he has no constructive system of his own, he has changed the combination of materials in his guns more than once, and even now he is far from satisfied he has adopted the best. From time to time it has eked out that new improvements in the building-up process have been introduced or proposed. His system is not the lead-coated shot compression plan of rifling, for that Sir William copied from Wahrendorf as he copied other parts of his gun from other inventors.

Can the moveable vent-piece be said to be the Armstrong system? It is by no means clear that the conception of that plan is the original offspring of his mind. The particular mode of its application he may probably lay claim to; but there can be no doubt that the vent-piece is the most faulty part of his heavy guns. Its weight for the 100-pounder is so great, nearly 2 cwt., that it requires two men to lift it in and out, and they find the operation excessively hard work. As a remedy, the side-wedge principle has been introduced; but this also has proved a failure. The escape of gas through the fissures, between the wedges, is so considerable, as to cause great waste of explosive force and rapid deterioration of the gun, to the extent of an alarming increase of danger of its bursting at the breech. The Parliamentary Ordnance Committee, appointed to examine into the Armstrong system, has been puzzled to determine what it is. After taking the evidence of the highest artillery authorities and the most eminent ordnance engineers, as the *resumé* of the answers to nearly 6,000 questions on this point, the Committee came the conclusion thus tersely expressed in their Report:—"This combination of construction, breech-loading, rifling, and coating the projectiles with soft metal came to be viewed as the Armstrong system." That is to say, they do not venture to affirm that this wholesale piracy of other men's ideas, is the the Armstrong system, but it *came to be viewed* as the system which has cost the country three millions.

What, then, is the Armstrong system? It is not, as we have shown and the Ordnauce Committee admits, any peculiarity in any part of the gun; for none of them, unless it be the vent-piece, the most defective part of the structure, is of his invention. That system is something independent of construction; it is an *idea* in his mind to which he would make any kind of gun subservient.

This predominating idea is "great projecting force combined with accuracy and long ranges with heavy projectiles and low charges fired from a rifled gun." To accomplish that *idea*, any gun which will carry it out, is good, in Sir William Armstrong's estimation, whether it be a "polygroove" or a "shunt," a muzzle or breech loader, or any other system. But the gun must be rifled and have little or no windage, in order to realize his idea of obtaining long range and increased intensity of explosion with low charges.

This idea has betrayed its author into the errors and failures of his so-called system. It has led him to abopt modes of rifling which are pre-eminently on the forcing plan, tending to "open the gun and split the metal;" and which cause an enormous waste of power by friction, as proved by the reduction of initial velocity, notwithstanding the increased energy of the explosive force.

To carry out his system, he relied on the the theory of momentum as the measure of propelling force. He calculated that, under all circumstances, the effect of projectiles would be in the ratio of the square of the velocity multiplied by the weight, and he inclined to the belief that, for smashing, if not for penetrating effect, weight would be more valuable than velocity. That such was the conception of his mind, I am warranted in asserting, by the earlier dispositions for the experiments with his gun at Shoeburyness. For the assaults on the "Warrior" and Iron Plate Committee's targets 200-pounder shot, fired from the 100-poonder gun, figured prominently in the programmes. The *Times*, the faithful exponent of Armstrongian vaticinations, exultingly dwelt upon the destructive effects of the tremendous 200-pounders. The gun, in those days, was always spoken of as a 200-pounder. When the trials came off, those heavy missiles were fired singly, and in salvos, at the armour-plates, but their performance was a *fiasco*.

To illustrate the view here presented of the real character of the Armstrong system and the cause of its break-down, I give the following data, which would long ago have been known if Government had allowed the reports of the Iron Plate Committee to be published, but they would not, and we may guess the reason why:—

Results of firing at the "Warrior" and Committee's targets at Shoeburyness.

Gun.	Weight of projectile.	Powder charge.	Velocities.
68-pounder smooth bore ...	68 lbs. ...	16 lbs. ...	1,580
100 " Armstrong rifled	110 lbs. ...	14 lbs. ...	1,200
100 " " "	200 lbs. ...	10 lbs. ...	900

Multiplying the squares of these velocities by the weights of the projectiles respectively, the following quantities work out as the momentum or force of the projectiles:—

68 lbs. shot	169,755,200
110 lbs. shot	161,051,000
200 lbs. shot	162,000,000

According to theory, these figures show that the forces are about equal; but in practice, the results, measured by indentations into the plates, were as follows:—

	inches.
68-pounder, mean indentation...............	2·35
110 " " "	1·75
200 " " "	·85

The conclusions to be drawn from these figures are inevitable. Practice has demolished theory. The heavy projectiles, with light charges, are beaten by the light projectiles

* M. W. Pole, F.R.S., and member of the Iron Plate Committee, has, in an interesting letter to the *Times*, given a description of two built-up wrought-iron bombardes still in existence at Mont St. Michel, in France, which were constructed more than 400 years ago.

with heavy charges. The old 68-pounder smooth-bore has driven the rifled Armstrong out of the field. The *Times* still, however, bolsters up its *protegé* although quite aware of the break-down of his system. It piteously exclaims, "but these are the results at 200 yards," and then, referring to long ranges exceeding 1,000 yards, audaciously declares "that if our experiments at home have not deceived us, Sir William Armstrong would knock the American 'Monitors' to pieces." How ludicrous and dishonest is this assertion, when it is known, and has been reported by the *Times*, that the experiments referred to prove that, at 200 yards' range, Armstrong guns make only slight indentations on armour plates, and produce no destructive effects whatever on the structure which they protect.

How long will the leading journal thus stultify itself, and deceive the public with the cuckoo cry of "Armstrong," after it has become notorious that his system is founded on a fallacy and is utterly worthless!

A correspondent of the *Times* quotes, from the Report of the Ordnance Select Committee, evidence of the Duke of Somerset to the effect that shot weighing 69 lbs. have been fired from the Armstrong rifled 110-pounder with the service charge (16 lbs.) of the 68-pounder smooth-bore, and that the initial velocity of the projectile so fired was greater than that of a 68-pounder. This result was obtained; but in artillery circles, it is well known the thing was abnormal—in fact, what the French call a *tour de force*. This ally of Sir William Armstrong omits to mention some facts which destroy the conclusions he wishes should be drawn from the experiments in question. The 16 lbs. charge was a straining charge which the Armstrong 110-pounder could not stand. Even the original service charge of that gun (14 lbs.) is too great; an order has been issued reducing it to 12 lbs. It is, then, a false pretence to adduce this evidence as proof that the 110-pounder can be used at short ranges with the same effect as the 68-pounder, or, in fact, that it can be fired at all in actual service. The comparison of initial velocity is unfairly made, by taking that of the 68-pounder with its ordinary windage of 5 per cent. of the area of the bore. Other experiments, which the *Times* leaves unnoticed, have proved that, by reducing the windage, the initial velocity of a round shot fired from a smooth-bore is increased from 1,500 to 1,800 and 2,000 ft., a velocity which the Armstrong cannot attain. What, then, is the use of showing that, for the special and exceptional purpose of display, a higher initial velocity has been forced out of the rifled 110-pounder, when it is known that the charge which produces it cannot be used in actual service without bursting the gun? CIVILIAN.

MANCHESTER BOILER ASSOCIATION.

AT the last ordinary monthly meeting of the Executive Committee of this Association, held at the offices, 41, Corporation-street, Manchester, on Tuesday, October 27, Mr. L. E. Fletcher, chief engineer, presented his monthly report, of which the following is an abstract:—

"During the past month there have been examined 300 engines and 440 boilers. Of the latter, 32 have been examined specially, 7 internally, 31 thoroughly, and 370 externally, in addition to which 2 of these boilers have been tested by hydraulic pressure. The following defects have been found in the boilers examined:—Fracture 6 (1 dangerous); corrosion 18 (2 dangerous); safety valves out of order, 8; water gauges ditto, 19 (4 dangerous); pressure gauges ditto, 14 (1 dangerous); feed apparatus ditto, 5 (1 dangerous); blow-out apparatus ditto, 43; fusible plugs ditto, 4; furnaces out of shape, 5 (2 dangerous); over-pressure, 3 (3 dangerous); blistered plates, 2. Total, 127 (14 dangerous). Boilers without glass water gauges, 11; without pressure gauges, 2; without blow-out apparatus, 13; without back-pressure valves, 43.

"The three furnaces reported above as out of shape, all became so from overheating, consequent upon shortness of water, the injury in each case being observed for the first time, on setting to work in the morning, after the boiler had been standing during the night with the fires banked up, while two of the cases of injury were first observed on a Monday. Each of the boilers had but a single glass water gauge, two of which were of the pillar construction, while all the boilers were fitted with fusible plugs, which proved inoperative in every instance. One of the boilers was fitted with a fusible plug in each furnace, both the crowns of which came down; the second was fitted with a fusible plug in the right-hand furnace only, and that was the one injured; while the third was fitted with a fusible plug in the left-hand fire-box, and the right-hand was the one injured; but in neither case did the fusible metal melt or give any sign.

"There are several ways in which the water supply may run short in a boiler left standing for the night with the fire banked up, all of which should be guarded against.

"Where there is only a single glass gauge, the attendant may be deceived as to the actual amount of water in the boiler; and thus the supply be left short overnight, unawares. It is well, therefore, to add a duplicate gauge, so that one may act as a check upon the accuracy of the other, this would frequently prevent mistake.

"Again, leakage may occur at the feed back-pressure valve, or at the blow-out tap, either from their being in bad condition or imperfectly closed. Engine-men are not sufficiently alive to the importance of examining these as a precaution, but leave them untouched until proved to be actually defective; whereas the feed back-pressure valve should be frequently taken out, and its free action ascertained; while the blow-out tap also should be examined, the plug cleaned and greased, as well as ground up, if necessary.

"A considerable safeguard also to furnace crowns would be found in a low water safety valve, which lets off the pressure of the steam on a deficiency of water occurring within the boiler. It may be true that it would not necessarily prevent the furnace crowns from becoming overheated, since the fire would go on burning if left to itself, after the water supply had run short; but as the valve would not admit of any accumulation of steam, the injury would be confined to the plates over the fire, unless, by excessive carelessness, the attendant should let in the water and get up steam in the morning without observing the distorted furnace crown. Such, however, could not occur without the most culpable blindness, against which it is impossible to provide.

"EXPLOSIONS.

"Five boilers, not under the inspection of this Association, have exploded during the past month, from which eight persons have been killed and four others injured. Three of the boilers have been personally examined since the explosion.

"The particulars of the first of these explosions may be briefly told. The boiler, which was not under the inspection of this Association, was the outer one of three working side by side and connected together, all of them being of the balloon or haystack class.

"Each of these boilers was of large diameter, the one in question being about 18 ft. at the base, the sides swelling to a still larger diameter at the springing of the hemispherical domed top. The bottom, which was arched, but had no stays to tie it to the crown, was worked into the sides by the plates being bent, and was seated upon a circular kerb of brickwork. Each of the boilers was fitted with a single safety valve, of rather a rough description, while it was stated that the working pressure had not exceeded 5 lbs., but that the exploded boiler, which was twenty years old, had already been repaired several times.

"Immediately over the brickwork seating, the plates for some distance round the boiler had been seriously affected by external corrosion, and reduced in places to one-eighth of an inch in thickness. It was from this cause that the rent occurred, the rent running circumferentially for a distance of 10 or 12 ft. parallel with the seating, and for the most part through the body of the plate. A portion of the bottom was blown down into the ashpit, where it remained, the rest of the shell flying to a distance of about 70 ft. across a public road adjoining, and carrying away a portion of the boiler shed in its flight. The engineer, as well as another man lying near to the boiler at the time, were both scalded, the latter dying shortly after in consequence.

"Competent inspection could not have failed to detect the dilapidated condition of the boiler; while this explosion shows that, however moderate the pressure may be, no boiler can be safely worked unless frequently submitted to a searching examination.

"The second explosion, from which one person was killed, arose from the collapse of the internal flue of a plain Cornish boiler, which was not under the inspection of this Association.

"The diameter of the shell was about 5 ft. 6 in., that of the flue 3 ft., the length of both 28 ft., the thickness of the plates generally three-eighths of an inch, but in the flues barely as much, while the steam pressure was 45 lb. per sq. inch. The collapse had extended from one end of the flue to the other, the portion over the fire being the least affected, while the remainder behind the bridge was completely flattened down. The boiler had not, however, stirred from its seat, or broken a steam-pipe joint, and all that was needed to resume work with the other two boilers, to which this was connected, was to close the junction valve. A rupture in an externally-fired boiler would have led to the dislocation of the whole series. The damage done by the last explosion of a boiler of that class was nearly £1,000.

"The cause of the explosion in question was obvious—viz., weakness of the flue. No flue of such dimensions as those just given can be safely worked with steam of a pressure of 45 lbs. on the square inch, unless strengthened either with hoops or flanged seams, or stayed in some other suitable manner. It may be true, however, that some such flues, though unstayed, are working, and have done so for years with steam of an equal or even a greater pressure than the above; still they are continuing to do so only at a risk, and their past immunity from collapse is no security against its occurrence in the future. Some flues gradually work themselves out of the circular shape, and thus become considerably weakened; while all should be placed beyond the suspicion of danger, especially as this can be done at so trifling an expense. For particulars of the best method of adding hoops to those flues which are already made, see the Association's monthly report of June, 1862.

"The fireman who was killed was standing in the front of the furnace at the time of the explosion, and blown, rake in hand, to a distance of about 60 ft.

"The third explosion occurred to a Cornish boiler with a single flue, internally fired, and not under the inspection of this Association. Fortunately, no one was injured, the explosion occurring during the dinner hour, when the men usually working near it were all absent.

"The boiler was set on two side walls. It was 23 ft. long; its diameter in the shell was 6 ft.; and in the furnace 3 ft. 6 in., which was reduced behind the fire bridge; while the thickness of the plates was seven-sixteenths of an inch.

"The simple cause of the explosion was external corrosion, the plates having been so eaten away as to be reduced to one-sixteenth of an inch in thickness. Two complete belts, the entire circumference of the boiler, and a plate wide, had severed themselves from it; while a third, which had rent in a somewhat spiral direction, and considerably overlapped a single circumference, lay opened out, and still attached to the shell. The two detached belts had fallen, one on each side of the original position of the boiler, doing considerable damage to property thereby; while the main part of it had moved but slightly from its original seating, although it had made a semi-revolution on its longitudinal axis, and lay bottom upwards. The chimney was shattered; the boiler-house, as well as an adjoining building, demolished, and some heavy machinery dismantled."

ELECTRO-MAGNETIC PHONOGRAPH.

THIS machine is capable of being attached to pianofortes, organs, and other keyed musical instruments, by means of which they are rendered melographic, that is, capable of writing down any music that is played upon them.

So keenly have musicians at all times felt the extreme tediousness of writing music by hand, and the impossibility of preserving the most valuable impromptu pieces in their full and flowing beauty, that immediately on the introduction of the pianoforte

into England strenuous efforts were made by men of inventive skill to supply the instrument with the means of registering the music performed upon it. "The first pianoforte seen in England was made by one Father Wood, an English monk at Rome, and by him sold to Samuel Crisp, Esq., who sold it again to Fulke Greville, Esq., for one hundred guineas."* This was about 1757.

The Rev. — Creed would appear to have been one of the first, if not the first, to think of constructing a melographic instrument, and in the year 1774 he sent to the Royal Society a Paper, entitled "A demonstration of the possibility of making a machine that will write extempore voluntaries, or other pieces of music, &c."†

There are also obscure accounts of a machine made in 1770, by a monk named Engramelle.

In a German work of 1774, John Frederick Unger a counsellor of justice at Berlin, claims priority of invention against Mr. Creed, though it seems most probable that each made a similar invention unknown to the other.

There is no doubt whatever that the Académie of Berlin was presented by Hohlfield—an ingenious mechanic who received some suggestions from Euler—with a machine which, to a limited extent, answered its purpose. It consisted of two cylinders moving paper between them, on which, by means of a crayon, each key made a mark when pressed down in the act of playing. But not only was the action of playing very fatiguing, but the music must have been of a most inconvenient width—that of the keyboard—and without any stave, accidentals, &c.; in fact a mere series of dots showing such and such keys were pressed down in the course of the performance, but utterly failing to mark the time, key, or accidentals. The Académie, however, in consideration of the great ingenuity of the contrivance, rewarded the inventor with a handsome gratuity.

In 1827, M. Carreyre made trial, before the Committee of the Fine Arts of the Institute of France, of a melographic piano, which consisted of a clockwork movement, which unwound from one cylinder to another a thin plate of lead, on which were impressed, by the action of the keys of the istrument, certain peculiar signs, which might be translated into the ordinary notation by means of an explanatory table.

"After the experiment, the plate of lead was removed, to make the translation, and a commission was appointed to report; but as no report was ever made, it is probable that the translation was not found to be exact. At the same time M. Baudouin read before the Institute a Paper, accompanying it with drawings, concerning another melographic piano; upon the merit of which we do not find that the Institute pronounced."‡

These accounts prove two important facts; the great efforts made and the small success achieved—this want of success proceeded from the lack of a proper motive power, none having used electro-magnetism—for it must be evident to all acquainted with music that these were as yet nothing more than partially successfully experiments, and produced no further results than stimulating inventors to continual exertions.

The causes of failure were many, the most serious being the oversight of endeavouring to derive the mechanical power from the keys the piano, whereas some power, which, while depending upon the action of the key for its liberation and manifestation, should at the same time exert its force without strain upon the key, still remained a desideratum. Such a power is electro-magnetism, as the mere motion of a piano key, without any alteration in the touch required—may be made to call forth a force of any magnitude required. Now, in Unger's machine the power was derived from the keys alone, and by direct action, thus rendering the touch of the piano so heavy that no one could perform properly upon it. For this reason it is unnecessary to consider further its defects. M. Carreyre's, besides being equally objectionoble on the score of its unavoidably heavy touch and arbitrary and unmeaning signs, produced at the best but an indented sheet of lead, a medium for writing music on most inconvenient and unmanageable.

A machine which should register in plain black and white on common paper the music performed, giving the score on the ordinary stave, using the flat, sharp, and natural signs, as in all modern music, accurately registering time, bars, legato and staccato, 8va, alto, and basso passages, and adapted to all keys, still remained a desideratum, for from 1827 to 1863 no further progress was made, though many continued to give their attention to the subject.

But in 1863 Mr. Fenby applied electro-magnetism, and a machine was patented by him, January 13, in that year, which, without altering the touch or appearance of an ordinary piano, is stated to be capable of registering the most complicated music.

Before giving any detailed description of the construction and capabilities of the phonograph, it may be well to point out the obstacles to be overcome in the notation, and thus to separate the possible from the impossible.

The most obvious difficulty—and one which, if not overcome, would render all other excellencies nearly, if not quite, futile—is the means of marking the various durations of the notes from the breve to the demisemiquaver, &c. This was a difficulty, inasmuch as the ordinary open, closed, and tailed notes cannot possibly be rendered available in an instrument registering that which is performed upon it.

The following considerations will render this apparent. The longest note is practically but the fusion of a number of shorter notes, from which it follows that on any particular key being depressed, as in playing, its first touch would be the shortest note of the notation, and the machine would immediately print such shortest note, and could not afterwards alter it; for to suppose a piece of machinery to render shorter or longer notes by arbitrary signs, having but a fictitious relation to their duration, is to suppose its possession of a reasoning power, the absurdity of which needs no comment. From these considerations, and others which will readily occur to the mind of the reader, it is manifest that some system is required in which the duration of sound and the performance of the printing may be co-existent, and thus produce a complete reciprocity of action between the two. In other words, a short note must be capable of becoming a long one in the printing as in the playing.

Bearing these facts in mind will lead to a complete comprehension and appreciation of the system. Each note shows the portion of time occupied in playing it by the length it occupies in the bar, and consists of a horizontal black line proportionate in length to the duration of the note, while the rest of the notation needs no comment, it being in all respects identical with that at present in use.

Having considered the notation, the next thing to which our attention will naturally turn is the mechanical appliances employed to produce this notation. First, then, as to the touch of the piano; this remains, to all intents and purposes, the same as if without the phonograph attached, as the mechanical power is not derived from the motion of the keys, but from a voltaic battery; the only part performed by the key being to bring a small brass stud, on its under side, in contact with a slender spring; this causes an electro-magnet to bring a tracer against the paper which is continually moving at a fixed rate and thus marks the note. When the key is no longer depressed, the tracing ceases, and the rod slides back; this mechanism being capable of registering the slowest or most rapid playing. The accidentals are printed by revolving type, acted on by the same sliding-rod and magnet. The accidentals are adapted for all keys, so that any number of flats or sharps may be correctly registered; the machine being capable of distinguishing accidentals, flats, sharps, and naturals from those which are proper to the key in which the music may be pitched—that is to say, if the key A natural be used, F, C, and G, when played sharp, will have no sharp sign in the body of the music, whereas if the naturals of these notes be struck, or the sharps of any others, suitable accidentals will be printed.

Having now reviewed the notes and signs proper to them, the bars will be considered. The barring of the music is performed in a simple manner, precluding the possibility of derangement, and is yet so accurate in adjustment that it correctly follows the accentuation of the most complicated piece of music. When a rallantando movement occurs, the bar or bars through which it runs will be actually lengthened in such a proportion as will accurately denote the character and expression of that part of the music. The same manifest advantages occur in the matter of legato and staccato movements.

The machine requires only blank paper, as it rules the stave and prints the score simultaneously. The inventor furnishes a small battery of convenient and simple form. The charge consists of sulphate of copper and water: one charge lasting for some months. The whole is in a neat drawer at the bottom of the machine, and offers nothing of difficulty or unpleasantness in its management, and requiring to be touched only to supply water to it.

* Rimbault's History of the "Pianoforte."
† Phil. Trans., vol. xliv., p. 445.
‡ Rimbault.

THE "FAR EAST."

THE launch of this vessel took place from Messrs. Dudgeon's building yard, at Cubitt-town, Millwall, on Saturday, in the presence of a large number of people, including Mr. J. E. Reed, Chief Constructor of the Navy; Mr. James Luke, Inspecting Officer of the Controller's Department of the Admiralty; Mr John Dinnen, Inspecting Engineer to the Admiralty; Vice-Admiral Sir Edward Belcher; Captain Thomas; E. Symonds, R.N., patentee of a system of double-keeled and screw vessels; and others whose names are well known in connection with marine engineering. The launch of any first-class ship that may be destined to take a part in the vast commercial enterprise between England and the most distant parts of the earth, must always be attended with a considerable degree of interest. In the present case, this interest was much enhanced by the fact of the "Far East" being the first vessel of her class to which the double or twin-screw system has been applied. Her principal dimensions are as follows:—Length between perpendiculars, 227 ft.; length of keel, 210 ft.; breadth of beam, 34 ft.; depth moulded, 22 ft.; depth of hold, 20 ft. 6 in.; depth at load water line, 17 ft.; displacement of hull, 2,200 tons; builders' measurement of tonnage, 1,270 tons. On her upper deck she has a capacious poop and forecastle, and the usual house and cabins amidships. She is fitted with engines of 150-horse power nominal, which drive a two-bladed lifting screw under each quarter. The engines have combined cylinders, the diameter of the high pressure cylinder being 24 in., and of the expansive cylinder 50 in., with a stroke of piston of 2 ft. The screws have each a diameter of 8 ft. 2 in., and a pitch of 16 ft. The two boilers have each six furnaces, with 109 square feet of firebar surface, and a tube surface of 1,883 ft. The shafting of the screws projects through a wrought-iron tube of great strength, which is bolted on to a false iron bulkhead, clear altogether of the ship's frame. This tube at its outer end is connected with a massive wrought-iron slide, which guides the screw to the well when being lifted, or to the shafting when being lowered. The ordinary "cross-coupling" by which the screw is connected with the shafting is superseded in the "Far East's" shaft by a square head at the end, which fits into a corresponding recess in the boss of the screw, which is connected by a thrust block fixed on a sliding rest. The screws are lifted by a worm and barrel; the whole arrangement for lifting the screws into their wells on each quarter looks perfectly efficient, and, at the same time, of that simplicity which is of itself the best recommendation of all similar mechanical arrangements. The launch was perfectly successful.

ARTIFICIAL MARBLE.

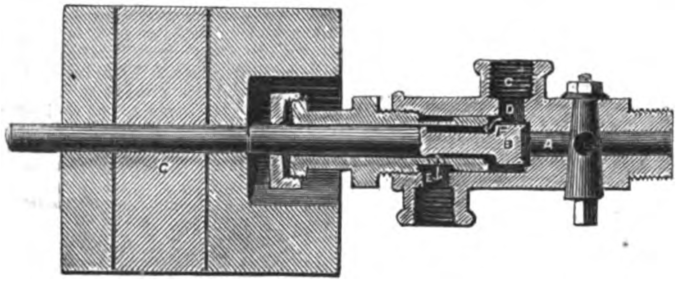
SIR JAMES HALL upon one occasion produced crystalline marble by subjecting chalk to a high heat in a close vessel. Professor Rose, of Berlin, Prussia, tried the experiment, and failing to produce such a result denied the correctness of Sir James Hall's statements. Being assured that crystalline marble had thus been produced, and that the specimens could be seen in London, he entered upon a second experiment, and in a recent communication to the Berlin Academy of Sciences, Professor Rose states that marble can be produced by exposing massive carbonate of lime to a high temperature under great pressure. His experiments were made with aragonite from Blin in Bohemia, and with lithographic limestone. In one case the mineral was heated in a wrought iron cylinder, and in the other in a porcelain bottle, the vessels being air-tight. They were exposed to a white heat for half an hour, and on cooling, both the aragonite and the lithographic limestone were found converted into crystalline limestone; the former resembling Carrara marble, and the latter a grey granular limestone. The change was effected without material decomposition; the resulting marble containing a trifle less carbonic acid than the lithographic limestone, from which it was produced.

It is announced in the Paris papers that the brothers Godard are about to make a balloon to contain 14,000 cubic metres of gas, whereas M. Nadar's "Giant" only contained 6,000.

CUTHELL'S IMPROVEMENTS IN SELF-ACTING DAMPERS FOR STEAM-ENGINE FURNACES.

In carrying this invention, by Mr. Alexander Cuthell, of Sketon, Lancashire, into effect, an equilibrium valve is placed in any convenient position between the boiler and cylinder, in connection with the steam-pipe, and capable of being adjusted to any required pressure by means of springs or weights. A piston working in a cylinder or some other analogous contrivance is employed, the valve being placed so as effectually to close the communication between the boiler and the cylinder and piston until the pressure of the steam in the boiler is above that at which the valve has been adjusted. The damper is connected with the piston by means of suitable rods or gearing, such as will be well understood by persons conversant with the construction of steam machinery. Upon the pressure of the steam in the boiler overcoming the resistance of the valve, the latter is actuated; and the steam being allowed to enter the before-mentioned cylinder, the piston consequently rises and the damper is lowered by the upward motion of the piston. The valve being upon the equilibrium principle is not affected by the pressure of the steam in the contrary direction after passing it, and the valve will consequently act freely under any variation of pressure in the boiler. The escape of steam from the cylinder may be effected by the action of the valve in shutting-off the communication between the boiler and the cylinder, by a small aperture at the bottom of the cylinder so constructed as to let off the steam gradually, and which aperture may be kept constantly open.

A, in the accompanying drawing, represents



the opening from the boiler; B is the moving part of the valve and the spindle combined; C, C, are the weights, through which the spindle passes; D is the opening to the cylinder; E is the waste steam pipe; G is the feed pipe to the cylinder. When the steam is of sufficient pressure to lift the valve B it acts on the piston, which moves the damper, the communication to the waste pipe being shut at F. When the pressure of the steam is reduced, the valve returns to the under seat, the steam from the cylinder being allowed to escape to the waste pipe, while the piston is allowed to return to its former position. It will be observed that the valve is represented as being adjusted by means of weights; but instead thereof, springs may be employed.

SOCIETY OF ENGINEERS.

Continued from page 723.

In April, 1861, Messrs. Shand and Mason supplied to the London Fire Brigade an engine (now stationed at Tooley-street) very similar in its general form to Braithwaite's, except that it has a slotted cross-head crank and fly-wheel, instead of the tappet motion, for working the slide valve, and is, to all intents, an ordinary donkey engine. The same boiler is used in this engine that was in the one last mentioned, and has been used at the Tooley-street Station up to the present time. I may, however, mention, that it will shortly take its departure from that station, and will be succeeded by my little "Princess of Wales."

In April, 1862, Messrs. Shand and Mason constructed another engine very similar to the last named, and called "No. 10." This engine is still working at the Wellclose-square Station.

In 1861, Messrs. Merryweather constructed an engine, the "Deluge;" but, as a description of this engine has already appeared in the Mechanics' Magazine, it is unnecessary to repeat it here.

About the same time, Mr. Roberts states that he constructed the *first self-propelling* steam fire engine in this country. A description of this engine has also appeared in the Mechanics' Magazine.

Mr. Roberts then alluded to the American steam fire engine which appeared in the American Department of the International Exhibition.

In April, 1862, Messrs. Shand and Mason supplied the engine "No. 10.," formerly described, to the London Fire Brigade, and this brings us up to the first competitive exhibition. Hitherto, Messrs. Shand and Mason had the whole run; but, by some means, Messrs. Merryweather had got permission to put their engine, the "Deluge," into the Exhibition; and Mr. Roberts considered that the manner in which the authorities of the Exhibition behaved in the matter of fire engines was most disgraceful. Messrs. Shand and Mason and Messrs. Merryweather and Co.'s exhibitions commenced at the main entrance, and were continued all over the building, and the engines of all other makers were stowed away in a sort of lumber room at one corner of the building, under one of the towers.

After the trials of hand engines, and when the "Deluge" was ready, the sub-committee decided to have the steamers tried; but, for reasons best known to themselves, Messrs. Lee and Larned declined to have their engine tested or tried. Mr. Roberts was in difficulties with the Benson boiler in his engine, and had not the London Fire Engine Establishment lent the engine "No. 10," and the one made by Shand and Mason, supplied to the London Fire Engine Establishment in June, 1862, Messrs. Merryweather and Sons would have walked over the course. As it was, a field day was got up: Messrs. Merryweather were the first to get up steam; but, unfortunately, the nut of their piston rod worked loose, and, for a time, disabled their engine; and, later in the day, they burst a pipe, which compelled them to withdraw from further trial. There can be no doubt that Messrs. Shand and Mason's engine "No. 10" worked the most comfortably, if I may use the expression, upon this trial. They were a considerable time longer getting steam; but, when it did start, it went off smoothly. Upon the other hand, Messrs. Merryweather's engine bumped in a very unpleasant manner, sometimes banging back and forward with sufficient force to break it up.

Shand's small engine worked very well; the most noticeable thing being the priming of the boiler. The boiler is a double-cone, the water space being between the two and the fire inside; the steam cylinders are single-acting, and placed over the pumps precisely as in the first float; the crank shaft is between them, but, instead of working in a slot, is connected to the pump piston, in the same manner as in the pump of 1858; the pumps are also single-acting, exactly as the first float; and like the hand engines, the engine had worked at 32 fires in six months, the average time at each being two to three hours.

As all the steam fire engines since made in London were tried at the Crystal Palace in July, we will now proceed to review these trials.

The jury, or, perhaps, more properly, the sub-committee of Class 8 in the late Exhibition, feeling that the three engines exhibited, or rather tried in Hyde-park, did not fairly represent the skill of this country, a movement was set on foot to get a fund, and offer such prizes as would induce other makers to come forward with engines.

A committee was formed and a sum of money obtained, and the following prizes offered—viz., £250 for the best, and £100 for the second best engine in each class, the classes being two—those between 30 and 60 cwt., and those under 30 cwt.

The chief points to which the committee directed their, or rather were to direct their, attention, in addition to the consideration of cost and weight, were those relating to the general efficiency of the machines as fire engines; combining among other points of excellence, rapidity of raising and generating steam; facility of drawing water; volume thrown; distance to which it can be projected with the least amount of loss; simplicity, accessibility, and durability of parts.

Upon the faith of this, seven makers entered their names for ten engines as follow:—

Merryweather and Sons, two; Shand, Mason, and Co., two; Butt and Co. (American), two; Easton and Amos, one (American design); Nicols (American), one, "Manhattan;" Gray and Son, one; and W. Roberts, one.

First, the "Torrent," by Merryweather and Son. This engine has been so often and so fully described in the pages of the Mechanics' Magazine, that it will be only necessary to say at present that it had been cut down or reduced in weight to bring it within the 30 cwt.; even the coal bunkers and foot-plate were taken off, rendering it for all practical purposes useless as a steam fire engine; yet still it was 1 qr. 12 lbs. over weight, but was allowed to work in the small class.

The next engine that Mr. Roberts described was the one made by Messrs. Easton and Amos, from designs by Messrs. Lee, and was, therefore, to all intents and purposes, an American engine. It was called the "Sabrina," but was formerly known as the "Annihilator," under which name it appeared at Lambeth. At this time its weight was 3 tons 2¼ cwt., but for the trial at the Crystal Palace was cut down to 2 tons 18 cwt. 3 qr. 12 lbs. This engine has been pretty fully described.

The engines that made their first appearance on the 1st of July were:—First, the "Sutherland," Merryweather, Son, and Field. The weight of the engine was 2 tons 18 cwt.; it has two steam cylinders 8½ in. diameter, with 24 in. stroke, the two pumps being 6½ in. diameter, also 24 in. stroke. The boiler is similar to the "Torrent's," and is described as being vertical, tubulous, circulating, shell of homogeneous metal, 5-16ths in. thick full, double rivetted; tube and top plate of Lowmoor iron, 11-16th in. thick; stays of bowling iron, 1 in. diameter; tubes of solid drawn copper, height 60 in., and will contain from 30 to 10 gallons of water (a rather wide margin) when at work. The pumps are the same description as those in the "Deluge" and the "Torrent;" the valve arrangement, which must have received an immense amount of consideration, is described in the Mechanics' Magazine of July the 10th.

At the trials on the 1st of July, this engine was second to get steam to 100 lbs. per inch, and show water, but was first into the hood, and, barring being occasionally short of steam, worked very well during the day, but nearly came to grief by cracking the end of the pumps. However, this was repaired in the course of the night, the engine being taken off the ground, a thing that I consider the committee ought not to have allowed on any consideration. The engines should have remained upon the ground, and, if incapable of going through the whole of the trials should have been disqualified. Mr. Roberts wished it to be clearly understood that he would not object to anything that could be done readily upon the grounds; but certainly the engines ought never to have left the grounds until the trials had ended.

On the second day, at the 18 ft. lift, this engine being primed, or rather the pumps and suction pipes, fetched the water immediately, from the simple reason they had no distance to fetch it, and filled the tank in 1 hr. 24 min. 55 sec., and against the water tower threw a 1⅛ jet 108 ft. high, for a few seconds, and was awarded the first prize of £250.

The next engine was by Shand, Mason, and Co., already described in the Mechanics' Magazine. The weight of this engine was 2 tons 17 cwt. 12 lb., and had two steam cylinders of 8¼ in. with 9 in. stroke, and water cylinders of 7 in. diameter, also 9 in. stroke, and appears to be just two of the engines used in "No. 10" (formerly described) placed side by side.

This engine was third to get steam to 100 lbs., the time being 11 min. 45 sec., instead of 10 min. 51 sec., as stated in the report; the water in this boiler was very unsteady, as might be expected from the closeness of the tubes, about ¼ in. apart.

Upon the second day's trial, there was considerable difficulty to fetch the water at the 18 ft. lift, the pumps had to be primed repeatedly, they not having a foot valve in the suction pipe, the water ran away before the rose could be got into the water, but when they did get to work they went on very steadily. At the trial against the tower for height, this engine threw a very steady stream, the jet being 1⅛ in., but from some cause did not long continue working. Mr. Roberts felt bound to say, that he believed the cause was that the committee had said that was sufficient, and Mr. Shand being anxious to get back to his small engine had drawn his fire.

The next engine mentioned in the awards was the one Mr. Roberts had the honour to exhibit, but which he did not intend to work in this class.

The boiler of this engine is 30 in. diameter and 20 in. high, and contains 248 $\frac{3}{4}$-in. tubes, screwed at each end so that each tube is a stay. The fire-box is 24 in. deep and is composed of 1-in. tubes, the lower ends being screwed into a water ring, and every alternate tube goes straight up into the lower tube plate; every other tube bends off when about 3 in. from the tube plate, and is carri d towards the centre of the tube plate, when they are screwed into places left for them. The feed water passes first into the ring at bottom, and then rising through the tubes passes into the boiler in thirty-two places; consequently, a certain supply is kept up among the tubes, the steam is taken off in the same way, and priming entirely prevented.

The steam cylinder is 7 in. diameter and 13 in. stroke, and has a common slide valve worked by an eccentric. The pump is one of Mr. Roberts' patent pumps; it is a plain cylinder $9\frac{1}{2}$ in. diameter, there is an axis working through the centre in stuffing boxes: upon this axis is a cross-head, in the top and bottom of the cylinder are buckets exactly alike; these are connected to the cross-head by forked rods and links, also duplicates of each other; upon one end of the axis there is a lever, and on the other a kind of bell crank. Two rods connect the ends of these levers to the cross-head of the engine; right under the slide jacket is a shaft running in suitable bearings and having the eccentric between them; upon one end of the shaft is a small fly-wheel, having a pin in one of the arms to serve as a crank; this is connected by a rod with the short arm of the bell crank lever. It will readily be seen by this that, as the piston works up and down, the buckets in the pumps advance to and recede from ea h other, causing a constant flow of water, not checked to that extent that it must be in all pumps where it has to be stopped and turned into another channel; it will also be seen that a rotary motion would be given to the eccentric shaft.

The stroke of the buckets of this pump is $3\frac{1}{4}$ in. each; it will, therefore, be seen that the water pistons or buckets travel at one-fourth the speed of the piston, also that all parts of the machine are readily got at.

This engine was *first to get steam to* 100 *lbs. and throw water;* but, from its position being placed to windward of all the others and its small size, it was of course beaten in quantity but not in steady working.

At the 18 ft. l ft it fetched the water immediately *without priming*, although a piece of canvas near half a yard square was afterwards found in the pump, and in the first hour's working it threw *exactly the same quantit of water into the water temple that Shand and Co.'s large engine did, viz.*, 20 *in.* Shortly after this, the head of a rivet came off, and the engine had to be worked easy, for fear of breaking down altogether.

Throughout the whole of the trials this engine worked steadily; there was scarcely any oscillation, no priming, very little variation in either steam or water pressure, and taking *power* into consid ration contrasts very favourably with the prize engines; thus, in the first trial, the "Sutherland," with steam cylinders more than *five and a-half times Mr. Roberts' capacity, and water cylinders six and three-quarter times the capacity of his pump, it took* 9 *min.* 42. *sec. to do the work that it took* 20 *min.* 24 *sec. to do with his;* the steam pressure at starting being the same, viz., 100 lbs. per inch, or, in other words, they did *two and one-quarter times* the work with *five and a-half times the power.* Again, if we take Shand, Mason, and Co.'s engine, we find its steam cylinders are more than *twice* the capacity of his, and the water cylinders *three and a-quarter times*, and yet it takes them 12 min. 19 sec. to fill their tank, *or one-fourth longer* than they should do it in, according to the time taken by Mr. Roberts' engine, and this, too, when from their position they had the benefit of all the spray from the other engines.

Again, if we take the third trial, which was, in fact, the principal trial, we find that Merryweather's engine delivered 16,086 gallons in 1 hr. 24 min. 55 sec., or say 189 gallons per minute, with an average steam pressure of 91 lbs., and water pressure of 89 lbs., and Mr. Roberts' engine delivered in the first hour before the rivet gave way, 5,560 gallons, or 92 per minute, just *half its more bulky competitor*, and this with an average pressure of 75 lbs. both steam and water, and if we take the whole two hours it brings us exactly the same as the first trial, viz. *two and a-quarter times the work for five and a-half times the power;* and as Shand's engine only delivered the same quantity in the first hour and not one-third more in the two hours, Mr. Robert's thought he had said enough to prove that the *best engine did not obtain either the first or the second prize*, and if they had taken trial at the water tower the case would not be altered.

Having previously described the "Annihilator," *alias* the "Sabrina," it is only necessary to say that it was fourth to get steam and di l very good work at the low lift, but could not accomplish the 18 ft. lift, and was finally withdrawn, the most noticeable point being that during the time it did work the average water pressure was only 41 lbs. to 98 lbs. steam.

We now come to the engine called the "Victoria," built by the Amoskeag Company, of America, and imported by Messrs. Lee, but entered under the name of Butt and Co. (We must refer our readers to the MECHANICS' MAGAZINE for a description of this engine.)

There was one other engine of which great expectations were formed—the "Manhattan," No. 8. This was sent over by the New York Fire Company, and was the crack engine there. This engine, in going to the place of trial, capsizes, seriously injuring one man. It was tried upon the second day, and considered fit for work by those in charge. It certainly threw a very good jet; but upon trying it the next day at the high lift and long range, it soon became evident that it was unable to do it, and finally came to grief by bursting the boss of the remaining fly-wheel. This engine was repaired, and afterwards tried at the Shadwell entrance to the London Docks, but totally failed to maintain its reputation.

There was one other engine entered for this class, one made by Gray and Sons, of Limehouse. This had a rotating boiler, but was not got to work.

We now come to the small class engines. Strictly speaking, there were none under 30 cwt. The "Torrent" had its coal bunkers and foot-plate taken off, besides other alterations. Shand, Mason, and Co.'s engine had no hose reel, although fitted for one; and Messrs. Lee's had some small parings to bring it to weight.

The steam cylinder of Messrs. Shand, Mason, and Co.'s engine was $7\frac{1}{2}$ in., with 8 in. stroke; the pump was of the combined bucket and plunger, the plunger being hollow. The crank shaft was placed fore and aft, and the fly-wheel athwartships, the connecting working in the hollow plunger. In the report the diameter of water cylinder is given as 9 in., but the diameter of plunger is not stated. The bucket has six and the foot-plate seven india-rubber disc valves, $2\frac{3}{4}$ in. diameter. The boiler was described in the MECHANICS' MAGAZINE, July 10.

This engine got up steam to 100 lbs. in 11 min. 36 sec., and filled the tank in 5 min. 24 sec.; on the third trial, steam was got up about 10 o'clock, but the engine could not be got to work—first, some shavings got into the pump and stopped, or rather prevented its working (he wished the canvas had served him the same), then something else went wrong, and, finally, it was got ready to start at 7 p.m., yet in the report the remark is "worked well throughout;" the report also states that the average pressure of steam was 146 lbs., and the water 80 lbs.; but when Mr. Roberts saw it at work the water did not exceed 60 lbs. He thought there must have been something very wrong here, 146 lbs. of steam, and 60 lb. only of water. His engine, with the same size jet, the same length of hose, the same lift, in all things similar, with 75 lbs. of steam, gave 75 lbs. of water. Lee and Co.'s "Victoria," with 78 lbs. steam gave 78 lbs. water; the "Sutherland," with 91 lbs. of steam, gave 89 lbs. water, again nearly equal; Shand's large engine, 96 lbs. steam, 62 lbs. water (one-third less); Easton and Amos, 98 lbs. steam to 41 lbs. water (this was worst of all); the "Torrent," 86 lbs. steam, and 45 lbs. water; and the "Alexandra," 80 lbs. steam, 60 lbs. water.

During the trial, the fire was from 1 ft. to 2 ft. above the top of the chimney, a state of things no boiler, with tubes made of 19-gauge iron, and spanned a fourth of an inch apart, can long stand. The oscillation of this engine was also fearful.

The "Alexandra," also made by the Amoskeag Company, and imported by Messrs. Lee, was in every way similar to the "Victoria," but smaller, having a $7\frac{3}{4}$ in. steam, and $7\frac{1}{4}$ in. water cylinder, with a $9\frac{1}{2}$ in. stroke; this engine got steam in 11 min. 55 sec., and filled the tank in 6 min. 3 sec., and at the long lift and range fetched the water directly, and worked on its allotted hour without stop, and obtained the second prize of £100.

The "Torrent" having been fully described, it is only necessary to say that it got steam to 100 lbs. per inch in 12 min. 15 sec., and filled the tank in 9 min. 15 sec.; at the third trial, very great difficulty was found to fetch the water—in fact, it was not until it had been repeatedly primed that it succeeded, but after it did get to work it went on very steadily.

Mr. Roberts then went on to say that, with regard to the committee, he felt bound to say he believed every member was actuated by the best motives, and thought they deserved the best thanks of society for the trouble they took in this matter, but they were unfortunately in the position of the man who tried to please everybody, and so pleased nobody; had they stuck to their rules, and carried them out to the letter, they would have been just as well thought of.

NEW MODE OF DRAWING METAL TUBES.

A POWERFUL hydraulic machine, embracing many constructive novelties, has recently undergone some severe tests at Johnstone, near Glasgow. The machine is for drawing tubes of cast steel and other metals from the cold bar, without join or weld, in the following manner:—A ronnd bar of cast steel has a hole pierced up the centre, and one end tapped to the depth of about $1\frac{3}{4}$ in. The piece of steel thus prepared has the tapped end—which is bevelled back about an $1\frac{1}{4}$ in., to admit of its being passed through a wordle or draw-plate, having a hole 1-16th in. smaller than the piece of steel to be drawn—secured to the end of the draw-rod, which is secured to the flange of the pist n; therefore, when the water is pumped into the cylinder, the piston is forced out, and in making its travel, draws the steel through the wordle; but were the drawing to take place from the surface alone, a considerable tensional strain would be thrown on the inner particles, but this is obviated by drawing over a mandril, having a bulb at the end, which not only eases the strain, but polishes the bore as well.

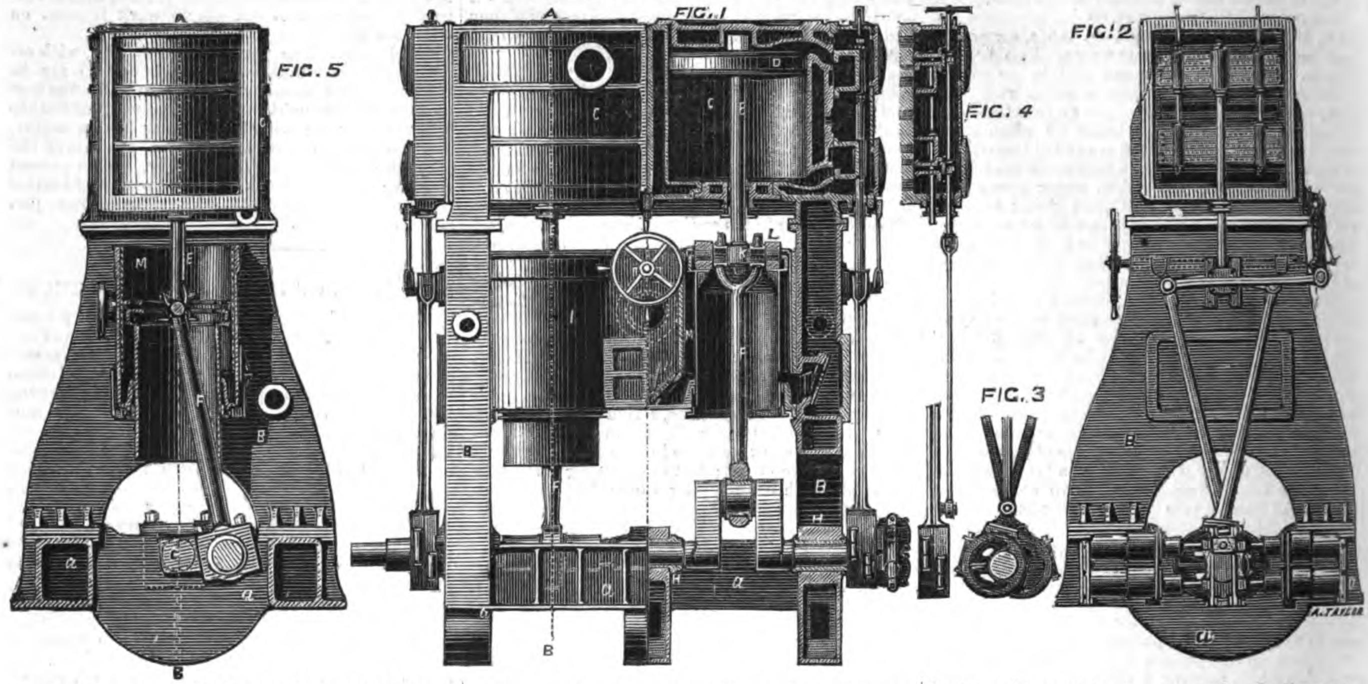
The recent trials consisted in passing several pieces of cast steel, about 2 in. diameter, through the wordles, reducing them 1-16th in. at each pass, and giving an elongation of about $1\frac{1}{4}$ in. to each pass. Now, when it is considered that cast steel is one of the most delicate metals to manipulate, even hot, some idea can be formed of the difficulty of working it in its cold state; but so great a command have the patentees obtained over this obdurate metal that they appear to work it almost as easily as lead. The quality of the steel is special, and the only make that has been found possessing the necessary ductility for being drawn cold is produced by Hawksworth and Co., who, for a number of years, have given special attention to the production of mild steels.

The machine—a ponderous affair of some 30 tons—consists of a double cylinder and double pistons, the cylinders having flanges at each end about 5 ft. square by 9 in. thick, and having recesses at given distances, into which draw-plates, or wordles, and mandrils are fitted. The cylinders are placed at a distance of 10 ft. apart, and a pist n, $16\frac{1}{4}$ in. diameter, gives motion to a cross-head or plate of the same size as the cylinder flange. Into these flanges steel draw-bars are secured. When the piston on the right hand side is home, the two flanges are together—in other words, the cross-head plate and the cylinder cover are in close approximation. The steel to be drawn is screwed into the draw-bar, when the piston, on being forced out with the water, pulls the steel through the draw-plate; and this is continued until the tube is brought to the proper size, the steel being annealed several times during the process.

For large tubes the steel is cast hollow, thus saving the cost of boring and the waste of metal. The patentees are sanguine of being able to make tubes large enough for the bore of the Armstrong gun. A large demand is also anticipated for them for boiler tubes, surface condensing tubes, piston-rods, hollow shafting, axles, gun and rifle barrels, &c. Some beautiful specimens were exhibited, drawn in Paris—where the patentees have been carrying on their experiments for some time—consisting of square tubes with square holes, square and octagon tubes with round holes, and round tubes various sizes; but the one that engaged the most attention was a portion of a 50 ft. one about 3-16ths in. diameter.

The *Glasgow Herald* states that the machine has been constructed, under the superintendence of one of the patentees, for a company in London, and leaves for there in a few days. Its power is equal to 600 tons pressure, and is the first of the kind constructed in Scotland, and for accuracy of workmanship and beauty of execution, reflects great credit on the maker, Mr. M'Arthur.

JACKSON AND WATKINS' STEAM ENGINES.



JACKSON AND WATKINS' IMPROVEMENTS IN STEAM ENGINES.

THIS invention, patented by Messrs. W. Jackson and R. Watkins, of Millwall, Engineers, relates chiefly to those forms of engines known as direct-acting engines, and whether such engines be vertical, horizontal, or inclined, and whether employed for marine or stationary purposes.

Instead of employing a guide block and guides, or any of the usual methods of guiding and supporting the outer end of the piston rod at its junction with the connecting rod, and instead also of working a pump by a lever or from off the crank by an eccentric or other means of communicating motion, the patentees effect these two objects of guiding the piston rod and working the pump by placing the pump barrel with its longitudinal axis in or nearly in a line with the cylinder, and between the cylinder and the crank shaft; and connecting the pump plunger or piston to the piston rod, and the end of the connecting rod of the engine by a fork end or any other suitable means; thus the pump is worked direct, and forms also the guide for the piston rod.

In condensing engines the air pump is the pump employed in this manner. The piston or plunger of the pump is of sufficient diameter to allow of a trunk large enough to permit of the connecting rod vibrating within it; and where the distance between the cylinder end and the crank shaft is limited, as is generally the case in marine engines, the patentees prefer to employ a single-acting and single trunk pump, the capacity of the pump chamber or barrel being regulated by the dimensions of the annular space, or the difference between the exterior diameter of the trunk and the interior diameter of the pump barrel.

In inverted direct-acting screw engines the valves may be placed at the bottom of each pump in direct communication with the condenser. In every case the connecting rod works within the trunk of a pump placed between the cylinder and the crank, and the cylinder of the pump and the packed end or ends thereof, or the piston and the gland alone are the means of guiding the piston rod, and of taking the thrust due to the angular motion of the connecting rod. For working the back slide or cut-off slide of double-slide valve engines, it is connected to the backward eccentric or its rod directly through a weigh shaft or by any other of the well-known means, and the amount of expansion regulated changing the positions of the slides by means of a screwed valve rod or other suitable means.

Fig. 1 is a general elevation or side view, one half in section, of a pair of inverted cylinder direct-acting screw engines, constructed in accordance with this invention; fig. 2 is a forward end elevation of fig. 1, the cover of the slide chest being removed the better to show the slide valve and face; fig. 3 is a transverse sectional view taken on the line A, B, fig. 1.

In each of the figures 1, 2, and 3, *a* is the sole plate, upon which the two hollow legs B, B, are bolted, and C, C, the steam cylinders bolted back to back and supported upon the hollow side frames or legs B, B, which form the condensing chambers; D, D, the pistons; E, E, the piston rods; and F, F, the connecting rods. The double crank shaft G is supported in the three bearings H, H, H, of the sole plate A. Between the side frames or hollow legs B, B, is fitted a casing I, for containing the two single trunk air pumps, the barrels of which also act as guides. At the upper end of each air pump trunk the fork end of the connecting rod is connected to a short cross head K, fitted upon the piston-rod end, and also secured in carriages L to the trunk and piston of the air pump M, and so admitting of the connecting rod vibrating within the air-pump trunk.

In figs. 1, 2, and 3 the forward and backward eccentrics, the link, and the gear for reversing are of the ordinary description, and the feeding and bilge pumps are placed horizontally at the fore end of the engine, as shown in figs. 1 and 2, and all four pumps are connected to a slot link, and are worked by means of a stud projecting from the face of one of the outer eccentrics of the forward engine, or the pumps might, if preferred, be worked by a pin fitted direct into the end of the crank shaft, or into a disc keyed to the crank shaft outside the eccentrics.

Fig. 4 is a sectional view of the valve face of the cylinders, the valve chest, and the main and expansion slide valves, with their rods and means of regulating the "cut-off" at the back of the main slide by separating or bringing together the two expansion slides or cover plates, by which the steam is admitted through the main slide to the steam ports. The rod of the main slide valve and the expansion valve rod pass through a gland in the slide chest, and are moved together by the eccentric gear; but the expansion valve rod is not connected to the link block, but by means of a rod or bar to a stud or pin projecting from the face of the backward eccentric strap or rod. On the upper end of the valve chest the rod of the expansion slide passes through a gland, and has a hand wheel or cross fitted thereon, for the purpose of turning it, and thereby changing the position of the expansion slides or cover plates in relation to the steam passages or openings through the main slide valve; the expansion valve rod is screwed with a right and left hand thread, and the lower end of the rod is made to turn or swivel when it is required that the degree of cut-off shall be changed.

The several parts of the apparatus for working the valve gear, and the several parts consisting of the valve face, valve chest, and covers, the slide valves and their rods, are so distinctly shown in the two figs. 2 and 4 as to render the employment of letters of reference unnecessary.

In adapting our invention to horizontal or other forms of direct-acting pumping engines for raising or forcing, or raising and forcing water, we apply a trunk pump of suitable dimensions placed between the cylinder and the crank as herein previously described, and for this purpose we may employ a double-acting pump with double trunk by increasing the length of the piston rod and the connecting rod.

PAGNY'S AGRICULTURAL IMPLEMENT FOR CULTIVATING ROOTS.

THE agricultural implement forming the subject of this invention, patented by M. Aimé Pagny, of Paris, is a ridge or bouting and at the same time a roller plough. It is composed of a ploughshare with double mould board (smaller than for ordinary bouting ploughs), and of four conical rollers acting on the inclined plane of the ridges. The share, the main object of which is not the bouting or ridging, breaks the sub-soil, cleans the water furrows, and thus prepares the work of the rollers, which follow it. The two first, which are placed on each side the mould boards, simply dress the earth; the two latter, on the contrary, which are more open, more inclined, and placed higher, press or settle down the earth and form the ridge. Four iron rods, hinged at S, S[1], (figs. 1 and 2 of the drawing), serve for axles, and receive four reversed conical rollers, that is to say, with their heads downwards. These rods slide freely at their upper part in two cross pieces, which may be compared to the branches of a compass. The head of this compass is about 12 in. apart behind the share, and the two branches, about 28 in. long, play at their

ends on a cross piece. A screw permits the opening to be adjusted at from 16 in. to 24 in., according to the greater or lesser pressure required. The inclination of the rollers is only equal two by two, because the fixing point at the base is the same, and the spreading apart of the points of the compass is more or less developed. Lastly, a wheel, about 8 in. in diameter, placed at the back of the plough, relieves the arms of the labourer, and it is this wheel G which keeps the two last rollers at an elevation of, say, 4 in., in order that they may more easily form the ridge.

PAGNY'S AGRICULTURAL IMPLEMENTS.

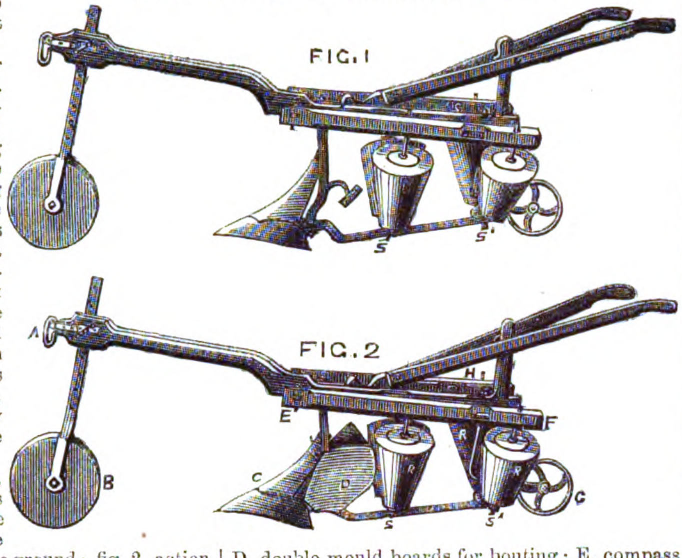


Fig. 1 in the drawing, action of the rollers when the ridges are formed, the tubercles, the seed, the colza being in the ground; fig. 2, action of the rollers, the virgin soil being turned up and the bouting or ridging being done.

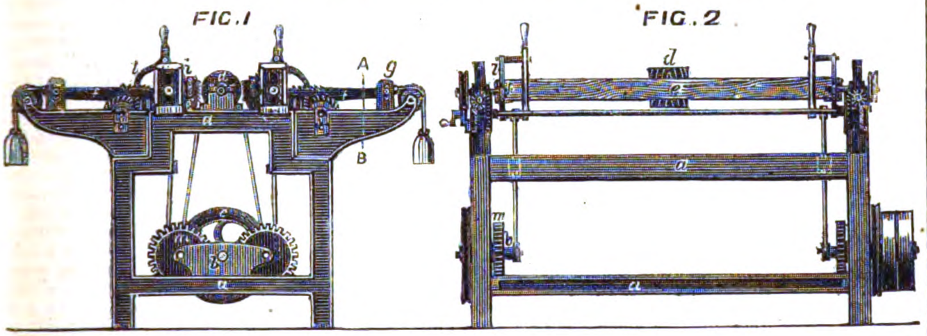
A, hook for harnessing; B, wheel which regulates the depth of the ploughing; C, ploughshare; D, double mould boards for bouting; E, compass head; F, branch of compass; H, pin which regulates the setting apart; G, hind wheel; R, rollers; S, S¹, point where rollers are hinged.

ALLEN AND JOHNSON'S IMPROVEMENTS IN GRINDING CARDS.



ALLEN AND JOHNSON'S IMPROVEMENTS IN GRINDING CARDS.

THIS invention, patented by Messrs. Allen and Johnson, of Cheadle, and Newton Moor, Cheshire, cotton spinners, relates to the small carding surfaces employed in carding engines generally attached to a continuous chain, and termed "flats," and is designed for the purpose of grinding the surface of such cards in an even and true concave form or in any other form desired.

The improvements consist in the novel employment and use of a guide or peculiar-shaped groove to cause the "flat" to approach and recede from the grinding cylinder at certain intervals so that such guide governs the superficial form into which the surface of the flat is ground. The form of the groove or guide will depend upon the particular form to which the "flat" is to be ground, whether truly vertical, simply curved, or S-shape, or diagonal. The flat is secured at the end of the radius rod or lever, the opposite end of such rod being furnished with a spring or weight, and at any point in the length of the rod a bowl or roller is attached, working or sliding in or against the aforesaid guide or groove, the weight or spring retaining the bowl in contact with the guide, and between the guide and the "flat" a connecting rod is attached adjustable in length, and connecting the radial rod with a crank, the revolution of which causes the rise and fall or vertical motion of the "flat," thus a double movement is given to the "flat," one horizontal by the guide, and the vertical one by the crank and connecting rod. The grinding cylinder may be placed between two flats thus arranged, and such apparatus as described be employed on each side.

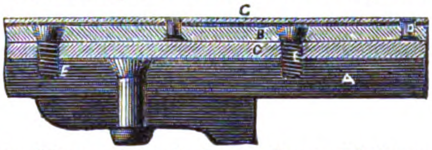
In the accompanying drawings, fig. 1 represents an end elevation of the apparatus for grinding and pointing the cards termed "flats" employed in carding fibrous materials, such view showing particularly the curved slot, by which means the shape into which the surface of the "flats" are to be ground is defined and regulated, and also shows one method of applying a reciprocating motion; fig. 2 is a front elevation, a portion being removed at the line A, B, in order to exhibit more clearly the gearing and internal construction.

In figs. 1 and 2, *a*, *a*, is the framing of the machine, in which is supported the driving shaft *b*, which drives by means of the strap and pulley *c*, a right and left-handed screw, and causes the roller and cylinder *d* to traverse from end to end of the two flats *e*, *e*, the application of this traverse motion and the means of effecting it being now well known, and the peculiarities and features of the grooved roller are explained in the specification of Letters Patent granted to Messrs. Allen and Johnson, dated January 24, 1863. The grinding roller *d* may either be used and constructed as therein described, or it may be employed without a corrugated surface as hitherto used, and is situated between the two "flats" to be ground, which are secured at the ends of the vibrating bars *f*, *f*, one end of such bars being supported in the bearings *g*, *g*, and are self-adjusting therein by being simply attached to the cord or weight which allows of any slight rise and fall. The course or curve which these bars, and consequently the "flats," are caused to follow, is regulated and defined by means of the curved (or straight) slots in the guides *h*, *h*; the surface of such flats are ground into a form corresponding to the form of the guide employed. The pressure of the flats against the grinding roller is obtained by means of the springs *l*, *l*, the amount of pressure being regulated by the ratchet and pawl *l*, by means of which the flats *e*, *e*, are prevented from becoming pressed too closely upon the grinding roller. The grinding roller is driven by means of the band and pulley *c* from the driving shaft *b*, and the vibratory motion or rise and fall of the bars and "flats" is effected by the crank studs on the spur wheels *m*, *m*, which are driven by a pinion on the driving shaft. The advantages arising from the employment of "needle-pointed" cards in the carding engine instead of the "chisel-pointed" as usually ground, together with the use of "flats" having their carding surfaces grooved truly to any required form, will be evident to all persons conversant with preparing and spinning cotton.

PALMER AND M'INTYRE'S METHOD OF APPLYING METAL SHEATHING TO IRON SHIPS, &c.

THIS invention, by Mr. C. M. Palmer and T. M'Intyre, of Jarrow, shipbuilders, has for its object the application and fastening of copper, "Muntz metal," zinc, or other metal used for the purposes of sheathing, to the bottoms of iron ships or vessels, and also to the iron used for other purposes, such as caissons, fortifications, or graving docks, in which it is liable to fouling by exposure to sea water or from other causes; and this invention consists in fixing to the iron plates of the ship or vessel, or to iron for other similar uses, strips of metal, by preference of galvanized iron, in which strips, are inserted rivets of copper or other suitable soft metal, such rivets protruding from the strips in such a manner as to admit of sheets of copper, "Muntz metal," zinc, or other sheathing, previously punched, being applied thereto and held thereby as required. By this arrangement the strips fixed to the vessel form carriers for the sheathing, and obviate the necessity of perforating through the ship's side. The strips are double—that is to say, there is one outer and one inner strip, and they are applied to the plates of the vessel by means of screws or rivets passing through both strips, and into the plates, the copper rivets having been previously inserted in an opposite direction in the outer strip. The sheets of copper or other sheathing are put on to the projecting copper rivets with their edges overlapping, so that the ends of two sheets are held by one row of rivets, and tarred felt, "blair," or other similar non-conducting material is inserted between the iron plates of the vessel and the copper or other metal sheathing. The projecting portions of copper are then hammered so as to securely rivet them.

The drawing is a vertical section of a portion



of a side vessel sheathed according to this invention.

A, A, are the plates; B, C, are the outer and inner strips of metal, which we prefer to be of galvanized iron. These strips have holes bored or punched in them at distances of about 3 in. apart, the side of the outer strip B having its holes countersunk to suit the countersunk heads of the rivets, and the two strips are rivetted together with the rivets D protruding beyond the outer strip B, the rivet heads being between the two strips. The strips are then fastened by screws or rivets E to the bottom and sides of the vessel, the plates A not being perforated but only entered, as shown. If the strips are to be rivetted, the holes are bored with a drill so constructed that it will be widest in the inside, so

that when the rivet is driven in it will expand and become quite fast. The space F between each pair of strips on the vessel's bottom and sides will be about ¾ in. deep, and is filled up with tarred felt, "blair," or other suitable non-conducting material, after which the entire surface is covered with a coating of gutta percha, and then the sheets G of copper, "Muntz metal," zinc, or other sheathing, previously punched as required, are applied to the rivets projecting from the strips and rivetted in the usual manner. The ordinary angle-iron frame of the vessel is represented at H. The strips can all be prepared ready to put on to the bottoms or sides of ships or vessels should repairs be necessary in a foreign port.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post-office orders made payable to Mr R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

SIR,—Can you or any of your correspondents give me, through the medium of your invaluable journal, any information on the following matters?—

1st. What is the quantity of atmospheric air consumed during combustion by a cubic foot of coal gas; and what is the volume of the products after combustion—all, of course, estimated at common atmospheric pressure?

2nd. What is the heating power of a cubic foot of gas—that is, what quantity of water will be raised, by the combustion of a cubic foot of gas, from, say, the temperature of 62 deg. Fahr. to the boiling point; and, also, what quantity would it actually convert into steam?

For any precise information on these questions I would be thankful.

I am Sir, respectfully yours,

MANCUNIENSIS.

Manchester, November 4, 1863.

RECEIVED.—M. M., I. F., W. C. and Co., D. K. C., W. J. J., I. K., I. H., Capt. L., W. W., J. N., I. H. R.

V. SMITH.—No chemical process will prevent the softening of gutta percha by the action of water sufficiently heated. You had better send post-office orders to Mr. Woodcroft if the sum is above five shillings. The postage will depend on the weight of the specification.

COLOUR.—There is a work of the kind you require, published in Weale's Rudimentary Series.

A SUBSCRIBER.—Any one who pleases may call himself a Civil Engineer. Legitimately, only those who have served a regular apprenticeship, so to speak, have a right to the title. In order to become a Member of the Institution, you must be more than twenty-five years of age, have been regularly educated as a Civil Engineer, according to the usual routine of pupilage, and have had subsequent employment for at least five years, in responsible situations, as Resident Engineer or otherwise, in some of the branches defined by the charter of the Institution as constituting the profession of a Civil Engineer; or, a candidate must have practised on his own account in the profession of a Civil Engineer for at least five years, and have acquired a considerable degree of eminence in the same.

C. B.—Your first letter was in type before the second reached us. Shall we insert it next week?

ERRATUM.—In a letter on Boiler Explosions in last week's MAGAZINE, for the "625th page" of the *Encyclopædia Britannica*, read, "635th page."

Correspondence.

GUNNERY AND ARMOUR PLATES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—It would ill suit me the task, and it would ill become me to indulge the idea of making your publication the medium for instructing your correspondent "Civilian" in the elementary principles of the science of mechanics; and yet until "Civilian" has cultivated an acquaintance with them—nay, until he has learned the language in which they are expressed, commencing even with the very alphabet thereof—it would needs be a farcial pleasantry to engage him in a discussion on scientific matters; neither is "Civilian" a modest man, or he would not say in opposition to what everybody else says, "I call velocity the *vis viva* because it is active, and I call weight the *vis inertiæ* because it is passive." Where and what are his credentials to warrant such an attempt to pervert the language of science, and in a manner, too, that betrays confusion in his mind as to those just ideas and distinctions concerning the realities of things, which it has taken thoughtful men so long a time to elucidate, and which they have long since stamped in words? Newton called a certain power in bodies as measured by the mass and the simple velocity, "quantity of motion;" but "Civilian" says "the quantity of motion" refers to velocity only. Since Newton's time the word "momentum" has been universally appropriated to this power and the said measure thereof; but "Civilian" says, "By momentum I mean the force of the moving body as represented theoretically [why theoretically?] by the square of the velocity multiplied by the weight." I have a faint suspicion that the authorities are against him, even that much-to-be-respected authority in all scientific matters to which he appeals—"the sense of words in their obvious and popular meaning." In the next paragraph, however, he says, "Equal quantities of momentum, products by calculation of varying quantities of velocity and weight, ought," &c. Now, which language are we to accept as the revelation of his ideas concerning the measure of momentum? And yet "Civilian" is the man to say that "precision of language . . . . is an object essential to fair discussion."

I pass on to a point more worthy of notice, because implicating experiments and facts, in regard to which persons more astute than "Civilian" may easily be led astray. But facts, as I before have had occasion to inform him, must receive a careful interpretation, embracing all their circumstances, before they can be taken in evidence for or against a principle. "Civilian" says triumphantly, "I will not give an opinion; I will confute him with facts;" but facts do become, through *his* interpretation of them, his own individual opinions, and, as such, they are not very likely to confute me. A man of a Mediæval turn of mind—that is to say, a man who substitutes fancies and loose slip-shod inferences for a severe investigation of things—has it in his power to point to very glaring facts in favour of a principle of levity antagonistic to that of gravitation. I am as enthusiastically in favour of facts, experiments, and practical knowledge as most persons, and, indeed, more so than meets the approval of the mere scientific man, relative to the comparative value of science and practice; but, on the other hand, I am bound to admit what the just cited instance, concerning the principle of levity, illustrates that facts are stubborn things, only as they are viewed in the light of true philosophy as founded on a far more comprehensive induction of other facts, and only so far as they are made the subject of strict examination under every aspect in which they can be presented.

The facts which are so signally to confute me, refer to the results of certain artillery experiments made at Shoeburyness; and the proposition advanced by me, which they are cited to demolish, is this; that, everything else being the same, the penetration of projectiles will be deepest where the material is most immoveable. Now, this proposition is a direct conclusion from the fundamental principles of mechanics, and is not to be shaken by ill-appreciated facts and experiments. Nay, the principal involved is universally acted upon, instinctively, as it were, by all artizans. Do we not find a difficulty in driving a nail in the middle of a board, when, being firm only at the ends, it vibrates to the blow? Do we not bring a heavy hammer on to the head of a nail or a rivet, when with a lighter one we wish to clench the one or batter down the end of the other? And do we not find, that, besides the utility of this expedient in preventing the nail or rivet being driven back, the effects of percussion are greatly intensified? Does not the blacksmith punch his iron on the firm anvil, and place it over a hole only when he drives out the detached piece? Do not our engineers seek to rival each other in the massiveness and immoveability of their anvils under the stroke of the steam hammer? Do they lay down as a foundation for such anvils a stratum of wool-sacks, or a bed of concrete? All practice testifies to the greater efficiency of percussive action, in overcoming, in various modes, the cohesive force of materials, in proportion as they are rendered firm and immoveable; and science, if asked, can tell the reason why. Even common sense dictates to the workman that he must not dissipate the force of the blow, in producing extraneous movements which he does not intend, nor movements of any kind in bodies on which he does not wish to operate.

Now, what are these artillery experiments, and these confuting facts by which "Civilian" pretends to justify a resort to rigidity and immoveability, when the object is to *diminish* the effects of percussive action? Four armour plates were attached respectively to solid cast iron, to solid granite, to solid wood, and to slabs of cork and india-rubber material. Under similar circumstances, as to the projectile, the penetration was slight in regard to plates with the iron and granite backings, but right through them with the wood and cork backings. And so it ought to have been. It would be a strange thing, indeed, if cast iron and granite had not afforded more help, more auxiliary resistance, in aid of that of the plates, than wood or cork. What was really put to the test was the strength of the several plates and that of their respective backings combined. If a ship can bear the weight, let iron and not wool be the immediate backing by all means; and then, by means of a wooden structure behind, let a certain degree of mobility be given to the whole, iron backing and all. But this is just the same as having the armour plates all the thicker by the thickness of the iron backing, only that the latter would be much better incorporated into the plate itself, when it would need no prophet to inform us, that a 6 in. plate would be more efficient than a 4 in. one. A mere thimble-rig trick is this figment about some particular value attaching in some prodigious degree to an iron backing. The weight and strength of iron being given, the pea is here if it is not there, or there if it is not here. Of course there is, in some moderate degree, a worse and a wiser choice in the disposition of the iron; but I give my vote in favour of a greater thickness in the plate.

Now, my proposition regarding the greater penetration incidental to rigidity and immoveability, embraced this proviso, that everything else should be the same; but in these experiments, everything was different, the plates being strengthened severally, by materials differing so greatly in powers of resistance, as cast iron, granite, wood, and cork. And yet "Civilian" is so little acute in analyzing and interpreting facts, as to say, "Everything else (but the yielding nature of the materials) was, as Mr. Cheverton desires, the same." A very peculiar sameness truly, when "everything else was the same *but*" the very materials which, as backing, imparted immensely different degrees of strength to the plates; for the rigidity or yielding of those materials indicated precisely the value of the auxiliary assistance afforded! To have everything else the same, there should be no backing at all; the use of rigidity or mobility should be tested, by having those qualities in the frames in which the plates should be set; or else, the plates should be so thick, that given shot should not only be unable to penetrate them, but be incapable of raising a bulge on the opposite side. The backing would not then be influential in direct resistance, but operative only in the desired direction of supplying different degrees of yielding and mobility. Each mode of experimenting would have its special advantages in the character of the results, rupture or simple indentation. I have not the slightest doubt that my proposition would be found to be correct—that, *cæteris paribus*, the depth of indentation is the greatest where the material is most immoveable. Else, indeed, all deductive reasoning, logical and mathematical, from firmly established natural principles, is a delusion and a snare.

The artillery experiments certainly present a specious side by which loose reasoners may be led, and misled, to adopt "Civilian's" conclusion, of "the superiority of rigid over elastic or yielding resistance to projectiles;" but I shall greatly be surprised if any man of scientific pretensions should fall into this error. Still, there is always an illusive speciousness about conclusions founded on experiments, although they may be ill-appreciated and falsely interpreted, and, therefore, I have not done wrong, I think, in debating a little upon this point; but, as to other points noticed by "Civilian," it will not be worth while to enter into further exposition.

Yours, &c.

BENJ. CHEVERTON.

[N.B. We have curtailed the latter part of this letter to avoid, if possible, entering on a personal controversy.—ED. M.M.]

BOILER EXPLOSIONS.

SIR,—Mr. Colburn leaves my last letter substantially unanswered. In writing the article, "Steam Engine" for the *Encyclopædia*, I stated that I had "consulted" the *Engineer*, as well as other works which are named. My "former as-

sistant" has been, and is, in Mr. Colburn's employment. I deny using the peculiar language imputed to me.

I thank you for the space you have allowed me; and I repeat, the question in discussion is scarcely suitable for your columns, and had better have been referred to competent persons,

Your obedient servant,
D. K. Clark.

11, Adam-street, Adelphi, W.C., Nov. 3, 1863.

STEERING BY TWIN-SCREWS, &c.

Sir,—Your Magazine almost weekly brings me vexation and disappointment, in the matter of my inventions adopted by others:—firstly, the auxiliary rudder, or side fins, for steering or stopping a screw steamer; secondly, propelling and steering by the single screw, as lately tried in H.M.S. "Charger," at Sheerness; thirdly, steering by twin-screws, as tried in H.M.S. steam launch "Experiment," at Portsmouth.

Most persons who take interest in nautical matters, know there is nothing new in twin-screws; but steering by twin-screws, as first fitted with separate engines to back, stop or reverse either screw at will without interfering with the other, so as to turn a screw steamer in her own length, was first made public in my experimental vessel "Ichthyon," on the Serpentine, in October, 1860, as witnessed by thousands, and noticed by the *Times*, *Daily News*, and certified to by Admiral Fletcher, Captain Target, and others.

I trust to your sense of justice to publish these facts in your Magazine.

I am, yours obediently,
George Beadon.

Creech Barrow, Taunton,
October 31, 1863.

Meetings for the Week.

Mon.—*Royal Geographical Soc.*, Sir R. Murchison, K.C.B., in the chair, 1, "On the Snowy Mountains of Eastern Equatorial Africa," with map, by Baron Charles von der Decken. 2, Last letter of the late Mr. Richard Thornton to Sir R. Murchison from Sheepanga, on the Zambesi. 3, The Niger Expedition—latest intelligence from Dr. Baikie. 4, Letters of the late Dr. Vogel, from the interior of Africa, at 8.30 p.m.
Medical Soc., at 8.30 p.m.

Tues.—*Inst. Civil Engineers*, "Description of Lighthouses lately erected in the Red Sea," by William Parkes, Esq., at 8 p.m.

Thur.—*Antiquaries*, at 8 p.m.

Sat. — *Architectural Assoc.*, "On Dwellings of the Poor, by H. A. Darbishire, Esq.

Miscellanea.

During the past week 39 wrecks have been reported, making a total for the present year of 1871.

The Lords of the Admiralty have ordered the removal of the Muntz's metal from the bottom of the iron-cased screw steamship "Royal Oak."

Some idea may be obtained of the costliness of the new railway improvements in the metropolis, when it is stated that the extension of the South-Western line from Nine Elms to the Waterloo-road —a distance of one mile— amounted to £1,000,000. It is estimated that the new line in London will cost on an average about £600,000 per mile.

On Monday a new monster dredging machine, very much more powerful than any hitherto employed on the Thames, was put to work, by order of the conservators of the river Thames, at Blackwall, in removing an excessively hard shoal formed of conglomerate gravel, which has hitherto resisted every effort made to rid the navigation of that important part of the river of so formidable an obstruction. The impediment, however, is giving way under the operation of the new machine, the engines of which are of 50-horse power. The new machine will be regularly employed in dredging and deepening other parts of the river, both below and above bridge, so soon as the shoal off Blackwall is removed.

Mr. L. Stebbins, of Worcester, Mass., has invented a sub-draining railway pavement, with which he proposes to cover the entire area of streets. It is made of iron; each block about 2 ft. square on the surface, and 2½ in. deep. There are four keys or square bolts to each square foot of surface. These keys rise ⅛ in. above the surface, and yield to the pressure of the horse's hoof. Each key rests on a rubber spring, which is secured in an iron tube. The inventor claims that it affords the best known surface for wheels to roll on; renders the slipping of horses impossible; and prevents, to a great extent, the accumulation of dirt, reducing the expense of cleaning streets

Two muzzle-loading 12-pounders, similar to the first Whitworth 12-pounder sent to the Royal Arsenal, have been received for trial, together with some cylinders with which to prove these guns. The peculiarites of these 12-pounders, which were specially made for the competitive trial against the six 12-pounders of Sir. W. Armstrong, similarly prepared, are that the vent is placed in the rear, instead of its usual place at the top of the gun, and that the angles shown in former rifling are swept out, leaving six rounded grooves. Against these three Whitworth 12-pounders, made out of blocks of mild steel, there will be tested by the Armstrong and Whitworth Committee, first, three breech-loading finely grooved Armstrongs, and three muzzle-loading Armstrong 12-pounders, rifled on his latest improved shunt plan. When this trial—which will be a most lengthened one—is concluded, another step in the competition will be taken and larger guns tried, probably three of the next calibre by Whitworth and six more by Armstrong, as he seems still in doubt whether brass buttons or zinc bars let into the shot form the best bearing for sizes above 12-pounders, and will, therefore, probably have three of each. One thing is, however, clear from this that Sir William not only mistrusts the breech-loading arrangements, but also his own especial plan of the inner tubes of coiled iron (both are unfortunately used in all the Armstrong guns in the service), for he relies upon his new "muzzle loader" for success, and has given his six competition 12-pounder steel tubes, or rather steel barrels, which are then finished with coils at the breech.

A prospectus has been issued of the National Steam Navigation Company, with a capital of £2,000,000, in shares of £100. The object is to accelerate the substitution of powerful screw-steamers for sailing vessels in the American and other trades; and the first step will be to establish lines from Liverpool to New York and from London to New York, of steamers of large size and great capacity, fitted for carrying grain, flour, provisions, and all other kinds of freight, and also for the conveyance of passengers. Three new steamers have been provisionally purchased, and contracts have been entered into for the building of others of about 3,500 tons each.

Considerable deposits of sulphur have lately been discovered in Corfu. This is but one of many significant facts cropping up, tending to show that the mineral resources of the Grecian and Ionian Islands are a "great unknown," awaiting but the establishment of order and confidence in the inhabitants to be manifested.

M. J. Giordano has described to the French Academy of Sciences an instrument, called by him a *bathoreometre* (depending, as to principle, on the closing of an electrical circuit by means of a substance interposed between the electrodes), whereby he is able to determine, with great exactitude, the thickness of very thin substances. A single thread of the silkworm was found to have a thickness of 0·014 of a millimetre; that of a spider (such as is used to divide the field of the telescopes), 0·037 mm. Hair from an infant's head is 0·009 mm., that of an adult averages 0·047 mm., in thickness. French gold-leaf has a thickness of 0·009 mm. A film of mica was obtained so wonderfully thin as 0·003 of a of a millimetre, or about twelve-millionths of an inch.

The target ordered to be constructed on a new principle, and with armour-plates of increased thickness to those at present in use, in order to enable the officials at the Admiralty to decide on the size of the plates with which the new iron frigate "Bellerophon," which has been commenced at Chatham, shall be coated, is to be erected at Shoeburyness, under the superintendence of Mr. Baskcomb, one of the officials from Chatham Dockyard. The principal object in having the target built is to test the strength of the timber backing and plates on the plan on which it is proposed to construct the sides of the "Bellerophon." To effect this the foundation of the target will consist of iron frames 10 in. in thickness and about 2 ft. apart, covered first with iron plates 2 in. in thickness, and afterwards with a backing of teak 1 ft. thick. The 6 in. armour-plates will be laid on the teak planking, the whole thus forming a target of immense strength. From the calculations already made, it is expected that this construction of side for the "Bellerophon" will surpass in shot-resisting strength every other system hitherto adopted in this country; and should the trials prove satisfactory, the "Bellerophon" will be formed in this way from stem to stern. The mechanics employed in the smithery at Chatham Dockyard are now engaged in making the heavy forgings for the "Bellerophon," in readiness for laying down the keel of that vessel in No. 2 dock; the "Achilles," which now occupies that dock, having been ordered to be ready for floating out by the 26th of December.

On Monday the British and Magnetic Telegraph Company successfully laid a submarine cable across the Bristol Channel at New Passage. This cable, which contains several wires, is intended to enable the Bristol and South Wales Union Railway Company to communicate from the Gloucestershire to the Monmouthshire shore, and *vice versa*, the Telegraph Company laying down additional wires, in order to afford greater facilities for the increasing business requirements between South Wales and Bristol.

American advices state that the Norfolk Navy Yard, which the rebels destroyed, has been in a great measure restored, at least so far that vessels-of-war are now repaired and altered at that station. There has not been much money expended on it, for a prejudice seems to exist against it; but Government officers, out of the ruins, have reconstructed the dry dock and converted the old pump into a new one at comparatively small cost. Nine vessels-of-war are now at the station undergoing repairs or being converted into "double-enders," and twenty-two have been altered and repaired. The wants of the service have been so exacting that everyplace where ships could be built or repaired has been required for Government use, and the Norfolk yard has forced itself into favour in consequence.

One of our exchanges says that there is considerable excitement just now in business circles connected with the Lake Superior trade, in consequence of the discovery of an immense deposit of silver-bearing lead in that famous region. It is stated that the ore yields 20 per cent. of pure lead, and that every ton of lead yields 25 lbs. of silver.

A great many English blockade-runners are now in New York overhauling and refitting, preparatory to being placed on the blockade. "Set a thief to catch a thief," on the old principle, we presume, of "setting a thief to catch a thief."

The Prime Minister is just now the subject of a considerable amount of scandal. But, judging from the extraordinary antecedents of the plaintiff's solicitors, we expect the affair will turn out a scandalous hoax. This "respectable firm of solicitors" owed us £2 5s. 6d. for advertising, and, after sending at least half-a-hundred times for the money, over a period of a year and a half, we had to summon them before the Sheriff's Court. They accordingly paid the money with the necessary costs. Many other papers in London could tell a similar tale, even the *Morning Star*, which first gave currency to the unfragrant rumour, included.

The Docks' Committee of the Bristol Town Council held a meeting on Saturday for the purpose of considering the scheme for river improvement which was debated at a former meeting. Mr. Howard, the Docks' engineer, brought forward a plan, which, in obedience to a resolution of the committee, he had prepared for improving the entrance to the Cumberland-basin, and thence to the Floating-harbour, and also of removing some objectionable features of the Avon. Mr. Howard proposes to cut off some of the points by which the tidal river is now rendered so tortuous, and by new and capacious locks, to enable ships of large burthen to enter the basin with greater facility and safety. He recommends that a new and commodious lock, with deep sills, should be cut through the piece of land which forms the south front of Jones's Coal-wharf, into Cumberland-basin, to enlarge the area of that dock, and to build a new wall on the north side of it; and then to cut a large and convenient lock through the slip at the eastern extremity of the basin, so as to admit of vessels being hauled in nearly a straight line into the part of the Float known as the Sea-banks. Mr. Howard estimates the cost of his proposed works at £320,000. The consideration of the scheme has been adjourned.

Some trials of a highly interesting character took place on the Royal Engineers' field-works, Chatham, on Tuesday week, in the presence of a large number of officers, for the purpose of testing a new description of suspension-bridge, for military purposes, the invention of Sergeant-major J. Jones, Royal Engineers. The bridge on which the experiments were made was formed of the galvanized iron

bands with which the new description of iron gabions now in use in the service are formed. These bands, which are about three inches in width, and the 30th part of an inch in thickness, were joined together at the end, by means of a button and eye, and, notwithstanding the apparent slenderness of the material, bore an enormous weight. Eight widths of the iron bands, each four bands thick, formed the "chains" of the suspension-bridge, and on these were laid the chesses, used in pontooning, which served as the floor of the bridge, the whole being steadied by means of guy ropes, fastened to stakes, answering to anchors in a river. With these materials a bridge having the enormous span of 130 ft. was formed by 30 sappers and miners in 6 hours. A battery of mounted field artillery was marched across with the greatest ease, the bridge having only a slight oscillation. A body of about 80 Royal Engineers was next marched across, in step; and this was the greatest strain to which the structure could be put. Notwithstanding this, however, the only perceptible defect was the great oscillation of the bridge, which ultimately loosened one of the guide ropes. In order to show the strength of the bridge a field gun with carriage, limber, and ammunition cart complete, was next wheeled across it, when gun, carriage, and men passed over without the bridge giving any sign of weakness. Some other experiments were also tried, all of which were exceedingly satisfactory, and proved the great value of bridges of that kind.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Boilers and Furnaces, 796, 816, 842.
Buildings and Building Materials, 789, 804.
Chemistry and Photography 821.
Cultivation of the Soil, including agricultural implements and machines, 807, 810, 822.
Electrical Apparatus, 830.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 785, 793, 798, 803, 805, 811, 820, 827, 828, 833.
Food and Beverages, including apparatus for preparing food for men and animals—*none.*
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 790, 792, 813, 814.
Letter-Press Printing—*none.*
Lighting, Heating, and Ventilating, 815, 817.
Metals, including apparatus for their manufacture, 783, 784, 788, 795, 802, 818, 819.
Miscellaneous, 824, 826.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 799, 808, 809, 812.
Ships and Boats, including their fittings, 786, 829, 831.
Steam Engines, &c., 825.
Warfare, 787, 797.

783. J. H. Johnson. *Improvements in the manufacture of zinc, and in apparatus employed therein.* (A communication.) Dated March 25, 1863.

This invention relates to the manufacture of zinc in blast furnaces, and consists of certain improvements in connection with the processes of smelting and of condensation. According to this invention, it is proposed that the fuel employed shall be raised to a high temperature in special furnaces before being supplied to the blast furnaces, which are to be closed at the top, and provided with a suitable cover or plug. This furnace is filled with fuel only, although if desired the ore and flux may be charged at the top of the furnace with the fuel; but according to this invention it is proposed to supply the furnaces with the ores and fluxes in a state of division by blowing the same into them through one or more blast pipes or tuyeres, the temperature of the ores and fluxes having been previously raised in suitable furnaces, kilns, or hearths. *Patent abandoned.*

784 T. W. Gore. *An improved method of uniting earthenware, metal, and other pipes.* Dated March 25, 1863.

This invention consists in uniting earthenware, metal, and other pipes formed with flanges on the ends thereof by means of a grooved collar formed in two or more parts. The ends of two flanged pipes which are to be united are laid in the lower half of a circular collar with a groove in the inner face thereof in which the flanges fit, the joint being made further tight if necessary by washers, cement, or packing. The other half of the circular collar is then passed over those parts of the flanges, not received within the lower half, and is made to fit on the edges of the lower half. For further security, if desired, a clamp or clamps may be fixed on the collar. *Patent abandoned.*

785. R. A. Brooman. *Improvements in the manufacture of cords, ropes, and cables, and in machinery employed therein, applicable also to spinning, winding, and twisting fibrous and filamentous substances.* (A communication.) Dated March 25, 1863.

This invention is not described apart from the drawings. *Patent completed.*

786. G. T. Key. *Improvements in fog signals.* Dated March 25, 1863.

This invention consists in the application of bellows to sound a wind instrument, such as a fog horn, the horn entering the bellows and forming the spout, or two or more differently sounding wind instruments—as, for example, a fog horn and whistle, for signalling during fogs and at other times. The bellows may be made in different ways—as, for example, single-acting, such as those in ordinary use for blowing fires, or double-acting, such as those used by blacksmiths. *Patent completed.*

787. L. Christofleau. *Improvements in firearms.* Dated March 26, 1863.

This invention is intended to be applied especially to sporting guns, and gives to firearms a greater security, and will prevent the numerous and fatal accidents which occur from the accidental discharge of firearms. The patentee takes off the trigger which, by projecting from beneath, may catch some impediment and cause the cock to fall upon the exploding cap, although the trigger is protected by the trigger guard, which is no longer wanted. No other piece but the cock is left to project, and as nothing can indirectly act upon the lock to remove the cock stop, the cock can no longer come down accidentally, and the less so, inasmuch as this trigger, which is even with the stock, and no longer underneath but on the upper part, is protected by a little sliding plate, which must be removed before the trigger can be pressed upon to fire the gun. The said trigger drives the end of a swing lever, the other end of which lifts the catch or stop which is engaged in a notch of the nut when the gun is cocked, the main spring working as in common gun-locks; the cock or hammer falls suddenly on the cap. *Patent completed.*

788. J. Mushet. *An improvement or improvements in treating steel and iron prepared by the pneumatic process.* Dated March 26, 1863.

The essence of this invention consists in thoroughly mixing, without the agency and deteriorating effects of the pneumatic blast, melted speigel eisen, or other melted alloys—such as alloys of tungsten of iron, or titanium of iron—with melted steel or malleable iron, prepared by the pneumatic process from melted pig iron or cast iron, which mixing the patentee effects either by the use of two or more pneumatic or decarbonizing vessels, each containing melted steel or malleable iron made by the pneumatic process, to the steel or malleable iron, in one or both of which two vessels the melted speigel eisen or other melted alloy has been added, the contents of one vessel being poured into the other vessel so as to internally mix and make the whole of uniform composition. Or by the use of one working pneumatic vessel, or of two or more working pneumatic vessels, in which the steel or malleable iron to be operated upon has been produced by decarbonizing melted pig or cast iron by the pneumatic process, and another or supplementary pneumatic vessel or pneumatic ladle, which, previous to use, has been intensely heated by having had pig or cast iron decarbonized in it by the pneumatic process, the melted speigel eisen or other melted alloy with which the steel or iron in the working pneumatic vessel or vessels is to be mixed being introduced into the heated pneumatic ladle, and the melted steel or malleable iron in the working pneumatic vessel or vessels being poured into the pneumatic ladle, and thereby intimately mixed with the melted speigel eisen, or other melted alloy contained in the said pneumatic ladle. Or the whole of the melted speigel eisen or other melted alloy may, after the blast has been withdrawn, be introduced into one of the said working vessels, each containing melted steel or malleable iron prepared from pig or cast iron by the pneumatic process, and the contents of the one pneumatic working vessel or of the several pneumatic vessels may then be poured into the intensely heated pneumatic ladle, whereby the melted steel or malleable iron and the melted speigel eisen or other melted alloy will, by the commotion of their particles, become thoroughly and uniformly mixed without the oxidizing and injurious effect produced when a blast of air is employed to effect a mixture of the before-mentioned melted substances. *Patent completed.*

789. G. Cowdery. *Improvements in machinery for making bricks.* Dated March 26, 1863.

This invention is not described apart from the drawings. *Patent completed.*

790. M. L. Parnell. *Improvements in the construction of locks, and in the method of adjusting their spindles.* Dated March 26, 1863.

The object of these improvements in the construction of locks is to prevent the stump in the bolt of a lock being pressed back against the cheeks of the levers, to detain false keys or picks by means of a detector or contrivance, to release the same without injury, and an easy mode of adjusting the knobs to the spindles of the same. *Patent completed.*

791. N. R. Hall. *Improvements in the construction of weighing apparatus.* Dated March 26, 1863.

This invention is based on the principle of the common steelyard, inasmuch as the article to be weighed is suspended at the short arm of the lever, but differs otherwise; for, instead of ascertaining the weight of an article by shifting or sliding a given weight upon the long arm until it is perfectly horizontal, the patentee allows the weighing apparatus to come to rest in any position, according as the weight of the article may draw it more or less from the horizontal line, and he then discovers the weight of the article sought by means of a hand which points to various figures representing weights, which said figures are marked upon a circle. This circle is at the extremity of one end of the weighing apparatus, and at the centre of this circle or dial the hand moves or plays freely upon a stationary pin, and the hand having a heavy tail end it will always maintain a perpendicular position when in use, and will, therefore, be directed to that number which is brought to a vertical position with the centre of the circle or dial. At the proper end for attaching the article to be weighed there is a suitable clip with hooks (or any convenient contrivance may be used) for attaching the article to be weighed; and when this weighing apparatus is hung or held up for use with the article properly suspended, the circle or dial will rise more or less, and one of the numbers marked upon it will be brought to a vertical position, to which said number the hand will be directed, and thereby indicate the weight of the article. *Patent completed.*

792. W. Johnson. *Improvements in pocket-books, purses, wallets, and bill-cases.* Dated March 26, 1863.

This invention consists in constructing pocket-books, purses, wallets, and bill-cases in such manner that the mouth or entrance into the compartments therein shall be kept closed until drawn open by the hand, whereby the contents of such compartments are prevented from falling out. The manner in which the patentee carries his invention into effect is by attaching one or more metal clip springs at the base with arms rising up the sides of the compartment, the mouth of which is to be kept closed as aforesaid. *Patent completed.*

793. T. Parkinson and J. Wood. *An improved application of embroidery to cotton printed fabrics.* Dated March 26, 1863.

This invention is designed to produce an economical substitute for the embroidered fabrics hitherto made of expensive material, such, for instance, as that class termed embroidered Bradford goods; and the improvement consists in embroidering with silk cotton fabrics which have previously been printed by ordinary processes to resemble or imitate better fabrics, so that, by the application of silk embroidery to cotton fabrics so printed, a novel manufacture is produced, wherein good appearance may be cheaply procured. *Patent abandoned.*

794. W. Tod and R. Paterson. *Improvements in portable apparatus for working drills and other instruments.* Dated March 26, 1863.

This invention relates to portable apparatus to be actuated by water or other fluid transmitted by tubing, for the purpose of working drills or other instruments which it may be desirable to move about from point to point. *Patent abandoned.*

795. G. Davies. *Improvements in engraving upon metals.* (A communication.) Dated March 26, 1863.

The principle upon which this invention is based is the application to engraving of the following well-known theory—that is to say, that when a certain metal is plunged into a saline solution containing a metal of the same kind, the solution is decomposed, and the metal reduced is precipitated on the former with a considerable degree of adhesion. It is the application of this principle to the art of engraving which the inventor wishes to secure to himself, without reference to the method of biting in, and although he gives the preference to certain solutions and certain plates, yet he can work equally well upon tin, copper, silver, or other metal by employing a solution belonging to a superior section to the metal—that is to say, a solution of a metal capable of precipitating itself thereon. *Patent completed.*

796. J. H. Johnson. *Improvements in furnaces or fireplaces, and in apparatus to be used in connection therewith.* (A communication.) Dated March 26, 1863.

This invention has for its object the obtaining of a better and more perfect combustion of small or inferior coal or fuel in steam boiler and other furnaces or fireplaces, and consists, chiefly, in a peculiar arrangement of apparatus to be adapted beneath the grates or fire-holding portions of furnaces or fireplaces, whereby an increased supply of air is directed into the burning fuel by the number of steam jets. *Patent abandoned.*

797. J. Norton. *Improvements in projectiles or ignition missiles.* Dated March 26, 1863.

This invention relates to the arrangement and construction of projectiles or ignition missiles suitable for igniting any inflammable body with which they may be brought into contact. Under one modification or system of arrangement, the shell—which is made of any suitable figure externally—is charged with liquid phosphorus. This solution is prepared by dissolving phosphorus in a suitable quantity of the bisulphide of carbon, and to this solution may be added, if required, a proportion of benzole for the purpose of increasing the inflammability of the solution. The front end of the shell is made so that it may be pierced in its passage from the gun. This may be done by placing a plug in the muzzle of the gun; the inner end of this plug is pointed or made with a piercer that will perforate the shell. On the gun being fired, the shell is impelled against the pointed part of the plug, which is driven out by the force of the blow, and does not further impede the flight of the shell. In the passage of the shell the liquid phosphorus slowly escapes from the apertures, and ignites on coming in contact with the atmosphere, and continues burning until the whole of the liquid is consumed. *Patent completed.*

798. W. Blake. *Improvements in the manufacture of labels for luggage and other articles.* Dated March 26, 1863.

This invention relates to the manufacture, application, and use of what may be termed compound paper in the manufacture of labels, such as are used for luggage and other articles. The raw material which is preferred for this improved manufacture is what is technically known as ammunition or cartridge paper, which is a thin strong clear paper. Two or more sheets or layers of this paper are laid together, and attached to each other by means of ordinary adhesive paste or other suitable attaching mate-
...well
...mer as

stance. This combined or compound paper is then rolled or otherwise treated with great pressure for the purpose of combining the sheets or layers into one solid mass. *Patent completed.*

799. F. APPLEGATE. *Improvements in railway carriage doors.* Dated March 26, 1863.

These improvements in railway carriage doors the inventor proposes to effect by using sliding doors instead of doors on hinges; the whole of the doors on both sides of the carriages (of course separate), or on one side, slide into recesses outside or inside, as preferred. He proposes to attach all these doors to a rod provided at the end of each carriage with a suitable expanding lining, or other mechanical equivalent, for connecting quickly, so that the guard at the end (or other compartment in which he is placed) can open all the doors at once when the train stops, and when the train has started to close them simultaneously. *Patent abandoned.*

800. E. EASTON. *An improved application of hydraulic apparatus for lowering full casks and other goods, and raising empty casks or vessels.* Dated March 26, 1863.

The chief object of this invention is to facilitate the deposit of barrels of beer in publicans' cellars, and the removal of empty casks therefrom. To this end, the inventor provides immediately below the trap or street entrance to the cellar a table or platform for receiving the barrels. This platform he mounts on a hydraulic ram, which works in a cylinder sunk in the ground to such a depth as will allow of the platform sinking to the level (or nearly so) of the cellar floor. *Patent abandoned.*

801. G. GRANTHAM. *Improvements in apparatus connected with machinery used in manufacturing compressed fuel.* Dated March 27, 1863.

This invention refers to machines with turn-tables or mould frames, upon which are affixed a certain number of moulds, and around which three operations are carried on nearly simultaneously—namely, 1, filling the mould with the small coal or other material; 2, subjecting the said material to the action of a hydraulic press for the purpose of solidifying or compressing it; 3, subjecting it to the action of another press for the purpose of discharging the block of fuel from the mould. The moulds are presented seriatim to these operations, and hitherto the turn-table has been moved by means of manual labour, which it is here proposed to effect by the use of hydraulic machinery. *Patent completed.*

802. W. M. MORGAN. *Improvements in coating metals, and in machinery and apparatus employed in coating metals.* Dated March 27, 1863.

The patentee claims—1, the use of fluxes consisting of chloride of zinc, or chloride of zinc and chloride of potassium, on the surfaces of baths employed for coating sheets or plates of iron and other metals with tin or lead, or alloys of tin and lead; 2, the general arrangement or combination of the parts of the machinery described and illustrated in the drawing for conducting the plates or sheets to be coated through the bath of melted metal. 3, applying to baths used for coating sheets or plates of iron or other metal with tin or lead, or alloys of tin and lead, at that side of the said baths from which the coated sheets or plates are withdrawn, two polished cast-steel, iron, copper, or other hard surfaces made to press upon the opposite sides of the coated plates or sheets, for the purpose of equalizing the quantity of metal on the coated plates or sheets, and smoothing the surfaces of the said coated plates or sheets as described. *Patent completed.*

803. R. A. BROOMAN. *Improvements in machinery for scouring wool.* (A communication.) Dated March 27, 1863.

This invention consists in the following arrangements of machinery for scouring wool:—The wool is supplied by a feeding apron or otherwise into one end of a long trough, and is taken hold of successively by a series of rakes or forks which are jointed to cranks carried by transverse shafts supported by uprights, which rise from the sides of the trough. Motion is communicated to the transverse shafts as follows:—The last transverse shaft is bent at one extremity, and carries a pulley which receives motion from a belt passing over another pulley, mounted on the same shaft as the main driving pulley; the motion thus imparted to this transverse shaft is transmitted to the other transverse shafts by means of bevel gearing and a longitudinal shaft. The wool being taken hold of by the rakes or forks as before mentioned, is conducted to the further end of the trough, where it is again taken hold of by another fork, which raises it out of the trough on to an apron, which leads it away to be pressed. This last-named fork is jointed to an axle which passes through the felloes of two toothed wheels, which receive rotary motion from pinions mounted on the principal shaft. The fork and a cam for raising it out of the trough revolve round two rollers, the fork is returned to the trough by a guide fixed to the sides of the trough, the operation is repeated as before, and so on successively. *Patent completed.*

804. J. TAYLOR, jun. *Improvements in the construction and arrangement of the rain-water pipes of buildings.* Dated March 27, 1863.

This invention has for its object the so constructing and arranging the rain-water pipes of buildings that they, and also the traps usually placed at their bottom ends, may be readily cleansed of any matters that may accumulate in them. For this purpose the patentee forms the lowest length of the number of lengths of pipe which together compose a rain-water pipe, and the bottom end of which descends into the trap, of greater diameter than the other pipes, in order that if there be any obstruction in the trap, or in the pipe, this lowest length may be slid upwards over the length of pipe above it, and thus leave a space between the trap and the lower end of the rain-water pipe; any matter that had accumulated in the trap can then be readily removed from it, or any obstruction in the pipe can be washed out at its end. The moveable length of pipe is formed with lugs or projections upon it, by which the pipe when raised can be held up, and by which also it is carried when in its lowest position. The rain-water pipes of buildings may also in a similar manner be made with one of the intermediate lengths of the pipe moveable; and this is a convenient arrangement when no trap is employed. For this purpose the length of pipe which is to be moveable is made of greater diameter than the other pipes, so that it may be slid over the pipe above, but at its lower end it is contracted so that it may there enter into the socket of the pipe below it. The moveable length of pipe is, as in the former case, made with projections upon it, by which the pipe when raised can be retained up. *Patent completed.*

805. W. CLARK. *Improvements in winding or copping frames.* (A communication.) Dated March 27, 1863.

This invention relates to improvements in self-acting and other winding or copping frames for spinning and twisting fibrous matters. The first improvement consists in replacing the sector or other apparatus for regulating the winding by a curvilinear section of a cone depending from the moveable carriage, and moveable on its axis; a chain passes round this cone, which is wound or unwound in proportion to the speed imparted to the spindles for producing the necessary number of turns. The second improvement consists in replacing the rule or copping plate conducting the faller in such machines by an apparatus similar to that before described, but, instead of having a chain to wind on and off the cone, the latter has a curvilinear surface in contact with an intermediate part suitably adjusted for imparting the necessary movement to the faller during the winding at the height necessary for the formation of the bobbin. The third improvement consists in replacing the scrolls or apparatus serving to produce the return motion of the carriage during the winding by an apparatus which permits of imparting a variable speed to the carriage by means of a cord or chain in connection with a combination of parts, to which is attached the one end of the cord or chain, the other end of the cord being acted on by suitable means for imparting a uniform speed thereto. The fourth improvement of this invention consists in imparting a recoil movement to the carriage during the pointing of the spindles, in order that the thread shall remain stretched without using a faller. *Patent completed.*

806. J. D. ASKWITH and G. GREENWOOD. *Improvements in rag machines.* Dated March 27, 1863.

This invention has for its object the separation of the untorn rags from the wool or fibre. This is effected by continuing, in the first place, the usual cover of the swift so that the rags (torn and untorn) are brought to the front part of the machine; and, secondly, by placing a casing of wood, or other suitable material, partly in front of and partly underneath the feed cloth of the machine. Within the casing the inventors place plates of wood or other suitable material in such positions that the untorn rags—by reason of the current of air created through the speed of the swift of the machine—are driven against them and fall down into recesses prepared for the purpose, whilst the torn wool or fibre is carried by the current of air through openings beyond the plates. *Patent abandoned.*

807. J. KING and T. H. MARSHALL. *Improvements in machinery or apparatus for preparing land for seed, and for harrowing and in fencing land.* Dated March 27, 1863.

In constructing machinery and apparatus for dibbling land, wheels are used with dibbles set on their peripheries. Such dibbles are arranged to be adjusted nearer to or further from each other, according to the distance apart at which it is desired to insert seed, and they are also each arranged in such manner as to have a movement when in the land in order to free them therefrom without breaking up and injuring the sides of the holes formed by them. It is preferred that a pair of such wheels should be mounted on the same axle, in such manner that they may be readily adjusted to and from each other, according to the distance apart it is desired to have the rows The axle carrying the dibble turns in bearings in a suitable frame. This frame at its centre is capable of turning on a short vertical axis, carried on the under side of a frame that is provided with shafts. The frame carrying the dibble wheels is provided with two handles or levers by which this frame can be inclined to the shafts, and the dibbles be thus steered or guided. The shaft upon which the dibble wheels turn is provided at each end with a rod which descends downwardly, and the lower ends of these rods, when the machine is at work, enter a short distance into the land, and thus, as the machine moves along, make lines along the ground. The machine can thus be readily guided by causing the rod on one side of the machine to be moved along the line previously made by the rod on the other side of the machine. In order that the machine may be drawn along a road or other suface without the dibbles coming in contact with such road or surface, the frame which is provided with shafts carries an axle on its upper side, which axle is provided with two road wheels. These wheels are of such a diameter that they shall be above the land when the dibble wheels are resting on it; these wheels can, however, be brought on to the land by turning over the shaft frame by means of the shafts; the dibble wheels will then be lifted off the land, as the rod upon which they turn will, by the frame having been turned over, be brought above the axle of the road wheels, in place of being below it. *Patent completed.*

808. B. W. GOODE. *A new journal, axle, or bearing, particularly applicable to rolls.* Dated March 28, 1863.

This invention relates to a new journal, axle, or bearing, by the use of which rolls, plain or with patterns cut or embossed upon them, may be changed with great facility without being obliged to take out the screws and brasses, as in the present usual arrangement, in which the rolls are solid or fixed on solid mandrils, and not, as in this invention, placed upon axles or mandrils revolving with the rolls. The patentee does not claim putting the rolls upon mandrils, solid or otherwise, but a more precise and effectual mode of fixing them, so that, when once fixed, they shall revolve perfectly true and correctly. The invention cannot be described without reference to the drawings. *Patent completed.*

809. A. H. PERRY. *Improvements in working railway points, switches, and signals, and in the apparatus to be employed for that purpose.* Dated March 28, 1863.

The object of this invention is to ensure to the pointsman or signalman a correct knowledge of the condition of the points or the signals (or both together, where they are connected and worked simultaneously) when either are worked or operated in one direction or the other, by which he will be enabled to work the traffic with safety over lines or junctions however complicated. For the purpose of ensuring the points or the signals being in the position intended or due to the movement of the lever handle by the pointsman, although he may be at a considerable distance from such signals and from the points, the inventor applies to each pair of points, and to the face or edge of the rail into which it is intended the point or tongue is to come in contact, a piece of copper or other suitable conducting metal, and by insulating each piece of metallic conducting surface from the rail or rails, and connecting it by means of a wire with a battery and telegraph instrument to the earth, the perfected contact is signalled on the opening or the closing of each pair of points or switches. *Patent abandoned.*

810. R. SIMS. *Improvements in reaping and mowing machines, part of which improvements is applicable to horse-works.* Dated March 28, 1863.

In carrying out this invention, the inventor employs an improved method of arranging the connecting rods of reaping and mowing machines, whereby the weight of the rod and its bush is removed from the crank pin to a guide or bush, such bush being situated at the rear end of the rod, the opposite or front end being formed of any convenient shape of joint for the purpose of attaching it to the knife-bar. In the aforesaid connecting rod, and at right angles to it laterally, he attaches or forms a slot for the reception of the crank pin which gives motion to the knife-bar. The slot is of any convenient length to admit of the throw of the crank, and of any convenient width to admit of a crank pin, with or without a hook or friction wheel or bush upon it, and at the same time to allow the pin with or without a bowl freedom of action in the slot. As the crank is turned round, the rod will advance and recede laterally without partaking of the rotary action or the rise and fall of the crank pin, this being rendered neutral by the pin traversing the aforesaid slot, and allowing the rod to move at any required angle to the line of the knife-bar, the rear bush of the connecting rod meanwhile occupying a position on either side of the slot. The inventor also employs an improved method of attaching the finger beam of reaping and mowing machines to the main frame by means of a hinged bar having its rear end secured to the frame by a flexible joint, and its front end connected to the finger beam by a similar contrivance, and by the combined action of the two joints the finger beam will accommodate itself to the irregularities of the ground as the machine advances to its work. Connected to, or formed upon, the aforesaid hinged bar, is a suitable fixing or joint, for the purpose of connecting it with a back stay, which is carried to the rear end of the main frame, and terminates in a joint which secures freedom of movement without confining the stay to any given line of action. The said joint is properly secured to the main frame, so that the stay will allow the finger beam to adjust itself to the irregularities of the ground, and at the same time retain the bar and finger beam at any required angle more or less from a right angle to the line of draught of the machine. The inventor also employs an improved mode of driving the knife crank spindle of reaping and mowing machines by means of worm wheel gear. *Patent abandoned.*

811. J. LEEMING and R. S. MARKINDALE. *An improvement in carding engines.* Dated March 28, 1863.

This invention relates to the class of machines known as carding engines, or machines employed in the preparation of fibrous materials for spinning, and for other purposes. In machines of this description there are sometimes employed in each machine two or more carding cylinders or swifts, the fibrous material in process of preparation in the machine being transferred from one carding cylinder or swift to another carding cylinder or swift by a doffer or doffing cylinder, one doffer or doffing cylinder only having hitherto been employed between any two carding cylinders or swifts. These improvements consist in employing in machines of the above description two or more doffers or doffing cylinders between any two carding cylinders or swifts for transferring the fibrous material from one carding cylinder or swift to another carding cylinder or swift, by which means the patentees are enabled to prepare with each machine a larger quantity of fibrous material in a given time than where one doffer or doffing cylinder only is employed, and also to improve the quality of the sliver and maintain the machine in a clearer and better working condition. *Patent completed.*

812. A. BLOUIN and D. N. MERCIER. *An improved axletree with linked levers for lifting.* Dated March 28, 1863.

This machine is composed—1, of a triangular framing with horizontal extension, the two sides of which are tied by bolts, other bolts serving to fix the frame to the ground; 2, of a large toothed wheel; 3, of three levers linked or jointed on the same axle; 4, of two eccentrics, to which are attached the arms of two of the levers; 5, of two toothed wheels on the same axle as the eccentrics. The axle of the said eccentrics and toothed gearing rests on a cast-iron piece or chair which forms a bearing between the eccentrics and the toothed wheels. This chair is attached to the framing resting against its extension. The axles of the above-mentioned eccentrics and toothed gearing have the shape of a crank; they are tied at their end by a bolt which passes at the same time in the slide of the third lever; 6 and last, of two other toothed wheels fixed on another shaft which receives a crank. The toothed wheel has three rows of teeth and a collar which may receive a break. It is on the axle of this wheel that the rope or chain attached

to the burden or load will roll. The teeth are arranged regularly, but so that those of each row alternate and receive the action of the levers one after the other. The levers have a slide which permits them to slide on a friction roller which unites them, some to the eccentrics, the other to the crank shafts which carry these same eccentrics. The same circular movement, therefore, sets the three levers in motion, and causes them to execute an alternate rise and fall. The head of the levers is traversed by the same axle; it is set to balance on one side only for the passage of the teeth, but a spiral spring bears it back immediately to its place. On turning the crank the two toothed wheels on its axle give motion to the two others, which are on the same axle as the eccentrics, and these as well as the said axle which forms the crank shaft set in motion the levers, which each rise and fall once during a turn or revolution of the eccentrics, and it is in this movement that the levers take by turns into the teeth of the wheel, and give it the rotary motion which is to lift the load. *Patent abandoned.*

813. W. SYMONDS. *Improvements in barometers.* Dated March 28, 1863.

The objects of this invention are to produce standard and other barometers in which the mercury is contained in a syphon tube, in which the reading takes place at one point and in which the mercury is stopped and the barometer rendered portable. *Patent completed.*

814. G. THOMAS. *Improvements in window shutters and window blinds.* Dated March 28, 1863.

This invention is not described apart from the drawings. *Patent abandoned.*

815. J. DALE and G. BISCHOF, jun. *Improvements in the manufacture of aniline, napthylamine, and other analogous bodies, and in apparatus connected therewith, which apparatus is also applicable to obtaining finely divided metallic iron for other purposes.* Dated March 28, 1863.

In the manufacture of aniline and analogous bodies there is a large quantity of metallic iron used, which is obtained chiefly from borings or turnings subsequently ground, so as to bring them into small particles. Now the first part of this invention consists in a method of producing metallic iron in a finely divided state. This is effected by submitting an oxide of the metal to such a heat as will effect its reduction, but will not fuse the metal. This process may be effected in a retort or other ordinary apparatus, but the patentees propose using a certain arrangement of furnace which is also applicable for obtaining the metal in the above-named condition for other purposes. The arrangement which they propose consists in placing the fire bars at one end of the furnace, and the flue at the opposite end, the working door being at the latter. In connection with the bed of the furnace there is an air-tight chamber, into which the reduced metal may be raked. This furnace may be provided with a charging door at the side to be closed air-tight during the operation. In reference to the manufacture of aniline, or other analogous body, the process may commence with the usual description of iron, and after it has become oxide, it may be reconverted into the metallic state for subsequent use as above described. For the purposes of producing finely divided iron applicable to the manufacture of aniline, they take an oxide of the metal, and, having ground it, mix therewith from 20 to 25 per cent. of small coal, or other carbonaceous matter. The mixture is then submitted to heat in any suitable apparatus (an ordinary retort for instance) until reduction of the metal is effected, care being taken to keep it below that temperature which would cause fusion. A red heat is the degree required, and the process will be completed in from eight to twelve hours. The finely divided metal thus obtained is liable in its heated state to become again oxidized if exposed to the air, and it is therefore desirable to adapt a vessel to the mouth of the retort into which the metal may be raked, and which may subsequently be closed up until the metal is cold. The finely divided iron thus obtained they use for the manufacture of aniline and analogous bodies in the same manner that iron is now used for that purpose. On commencing the manufacture of aniline or analogous body the usual turnings or borings of iron may be employed. These during the process become oxidized, and are therefore in the proper condition for being converted into the finely divided metal as above described. *Patent completed.*

816. J. MUSGRAVE. *Improvements in the construction of steam boilers.* Dated March 30, 1863.

This invention is applicable to steam boilers having two longitudinal flues containing at one end the fire-grates. These flues extend from one end of the boiler to the other, and impart the requisite strength to the ends, but they are closed near the bridge at the firing end, either by partitions of fire-brick, or otherwise. The products of combustion descend through vertical flues into an external horizontal flue; they then pass along external flues to the end of the boiler, where they enter the end of the internal flues, from whence they descend through vertical flues into an external flue, which is in communication with the chimney. *Patent completed.*

817. T. BARNES. *Improvements in treating fats and fatty oils, and volatile oils or essential oils.* Dated March 30, 1863.

This invention consists in a new and novel mode of decolouring, deodorizing, and indurating fats, oils, and oleaginous bodies, by the use of sulphuric acid gas and carbonic acid gas, in combination with atmospheric air, or alone, so as to deodorize and indurate the same. *Patent abandoned.*

818. R. MUSHET. *An improvement or improvements in moulds to be used for casting steel or homogeneous iron.* Dated March 30, 1863.

This invention consists in making moulds to be used for casting steel or homogeneous iron either wholly or mainly of sheet iron. *Patent completed.*

819. H. HUGHES. *Improvements in machinery for shaping metal and plastic substances.* Dated March 30, 1863.

This invention consists in shaping metal and plastic substances by means of a set of two, three, or more rolls, cut or formed with the shape or pattern to be produced, in a spiral direction from end to end of the rolls. The rolls are driven at the same speed, and in the same direction, and the metal or plastic material is presented to the rolls in a line parallel to the axis thereof, or nearly so, and by the rotation of the rolls is carried through between them in a direction at right angles, or nearly so, to that of their rotation. The patentee employs guides to keep the articles in their proper position while passing through the rolls. *Patent completed.*

820. J. CARVER. *Improvements in the manufacture of carriages employed in machines for the making of lace or other fabrics.* Dated March 30, 1863.

Heretofore, in carriages employed in machines for the manufacture of lace or other fabrics the springs which hold the bobbins in place have been fixed at the side of the carriages at about the centre of the bobbins, which arrangement has necessitated the use of springs of considerable length, thus rendering the bobbins liable to lean or project over the side of the carriages, so that the warp threads become likely to enter the bobbins, and so occasion injury to the lace or fabric and loss of time; and, moreover, in the said arrangement as heretofore used, a space being necessarily left in the carriage between the bobbin and the root of the spring, knots, burrs, or other unevenness of the thread or material wound on the bobbin become liable to drag or impede its revolution, and thereby cause instantaneous fracture of such thread or material, so as to render it inexpedient to wind the bobbins full of thread, or even nearly so, in consequence of the thread dragging at the before-mentioned space. The object of this invention is to remedy these defects; and for this purpose the patentee fills up the aforesaid open space by using in a carriage of any given size a larger bobbin than than has heretofore been used in a carriage of such size, and he places the spring at the top part of the carriage, or nearly so, instead of at the side thereof, as heretofore, so that when the top of the carriages are pressed by the warp threads, the springs will keep the bobbins perfectly upright in the carriages, and thus prevent the warp threads from entering the bobbins. The space between the carriage and the bobbin being thus filled up, the size of the carriage can be reduced, and "more lead" (as it is called) can be given to the carriage. The improved arrangement also allows of the employment in a carriage (of any required size) of a larger bobbin than has heretofore been used (in a carriage of such size); and as upon such larger bobbin a larger quantity of thread or material can be wound than on a smaller bobbin, pieces of lace or fabric can be produced of greater length than could have hitherto been produced with bobbins in carriages of the same dimensions under the old arrangement. *Patent completed.*

821. W. E. NEWTON. *An improved process for producing yellow colouring matters and other colours which may be derived therefrom.* (A communication.) Dated March 30, 1863.

This invention consists in a novel process for obtaining from napthaline a yellow dye, which may be used either alone for dyeing yarns or threads and piece goods, or be treated with suitable chemical reagents for varying its hue, as desired. The following is the mode of carrying out the improved process:—The patentee takes 100 kilogrammes of napthaline, and boils the same for a few hours in an acid solution composed of 200 kilogrammes of water and 20 kilogrammes of nitric acid at 30 degs. Beaumé. The napthaline must be kept well stirred while dissolving in the boiling water and acid, and the agitation must be maintained until the mixture has become cold. He next draws off the mother liquor, and the napthaline will then present the appearance of brown crystals. These crystals are now to be well washed in cold water to remove the acid. In order to obtain a yellow solution of colouring matter, the crystalline product is to be treated with boiling water, to which is added 5 kilogrammes of liquid ammonia. The solution thus obtained is to be filtered, and subsequently evaporated into a concentrated state. The concentrated solution must in like manner be filtered, and when cold it will be ready for use. *Patent completed.*

822. W. AGER. *Improvements in machinery or apparatus for cleaning and decorticating grain.* Dated March 30, 1863.

According to this invention, it is proposed to employ a modification of the well known barley mill, but to adopt an arrangement whereby a current or currents of air may be directed through the rice or other grain during the operation of cleaning the grain and removing the inner pellicle. For the better action of the currents of air upon the rice or other grain a number of ledges or projections are fitted longitudinally to the interior of the revolving screen or outer casing, which ledges serve to carry up the grain, and allow it to descend again to the bottom of the casing, the current or currents of air being directed through the falling grain, and carrying off the dust or flour produced by the action of the decorticating stones, thus leaving the rice or other grain perfectly clean and free from the inner pellicle. *Patent abandoned.*

823. J. PAYNE. *Improvements in fire-escapes.* Dated March 30, 1863.

Under one modification, the improved fire-escape consists of a simple open rectangular framework to be placed inside the window of the house. This frame may be constructed so as to have the appearance of a piece of furniture —a settee or ottoman, for instance. On this frame is disposed, in end bearings, a horizontal chain or rope barrel, cylinder, or winding drum, the spindle of which is fitted with ratchet gearing and pawls. Attached to and wound upon or over this cylinder or barrel is a chain or rope ladder, the loose free end of which is fitted with a transverse or cross bar having a hook or clipping holding piece at each end for attachment to any suitable fixture in the street or road outside the house. In this way, or by these means, whenever a fire occurs, the chain or rope ladder can be wound off the cylinder or barrel from within, and the ladder can thus be let down from the window so as to reach the ground outside the house. *Patent abandoned.*

824. E. T. HUGHES. *An improved composition for rendering, cloth, paper, and similar articles transparent and waterproof.* (A communication.) Dated March 31, 1863.

This composition is composed of one part by measure of linseed oil, one part by measure of india-rubber cement, and six parts by measure of benzine. This, for most purposes, constitutes probably the best mixture; but for a preparation of tracing cloth and tracing paper of close texture it may be advisable to use an additional proportion of benzine, to avoid producing a gloss on the outside, and also to avoid filling the pores of the paper too full to retain the ink and colours which may be applied. *Patent completed.*

825. J. SMETHURST. *Improvements in steam engines and boilers, part of which improvements is applicable to heating purposes.* Dated March 31, 1863.

In carrying out this invention, the patentee employs a compound boiler, consisting of an inner and outer shell, and as he proposes having a much greater pressure in the inner shell than will be in the outer, the steam from the former is intended to supply a high-pressure engine, the exhaust steam from which will pass through pipes to another high-pressure cylinder of larger size, or to a condenser, or directly into the outer shell of the compound boiler, and will thus pass with the steam generated in the said outer shell (unless discharged into a large cylinder or into a condenser) to another high-pressure cylinder, from which the exhaust steam will pass through pipes to a low-pressure condensing steam engine, or into a condenser, or through a series of pipes so arranged in the various rooms of a building as to be serviceable for heating and other purposes, as also for surface condensation. *Patent completed.*

826. A. B. D. MAURAND. *A translucid, cylindric apparatus for bringing the former weights and measures into those of the present decimal system most easily and precisely, and vice versa.* Dated March 31, 1863.

This invention is not described apart from the drawings. *Patent completed.*

827. R. FURNIVAL. *Improvements in and applicable to plaiting or braiding machines.* Dated March 31, 1863.

This invention consists—1, in the use of arrangements accomplishing the objects above described by alternately and at regular intervals arresting the motion of the threads from each other at a point between the focas and the bobbins, and then releasing them; and the improvements may be carried out by various means—namely, by a circle or surface carrying teeth which can pass through all (or a part only if required) the spaces between the threads at the same time, this toothed circle or surface being arranged on a vertical rod, which has an up-and-down motion imparted to it by a cam, so that when elevated its teeth pass between and interrupt the motion of the threads, and when lowered the teeth are withdrawn from the threads, which are thus released and allowed to assume their natural position when unobstructed. The invention consists—2, in introducing pushers between the threads all round the focas, so as to enter between them and push the plaits or twist towards the focas; and this action may be combined with that described in the first part of the invention, by making the teeth inclined on the upper edge, the incline being upwards from the inner circumference to the outer circumference, so that the outer point of the teeth will first pass between the threads, and as the surface carrying the teeth is lifted, the incline of the teeth will drive the plaits forward towards the focas. *Patent abandoned.*

828. W. FORREST and H. DUCKWORTH. *Improvements in looms for weaving.* Dated March 31, 1863.

This invention relates—1, to the traverse of the slay or lathe. The improvements consist in arranging the bearings which carry the ends of the crank arms working the sword arms or lathe or slay in such a manner as that their positions may be altered by raising or lowering them at pleasure, by which means the inventors are enabled to regulate the traverse of the lathe or slay in order to accommodate the loom to different kinds of goods and qualities of yarn. The second part of the invention relates to the "wing," which, in looms as heretofore constructed, requires lifting over the "frog" at each and every pick, except in case of concussion, or when from any cause the shuttle does not shed properly. The object is to dispense with the usual lifting of the wing, by which means the inventors are enabled to run a fast reed loom as quick or pick as often as with a loose reed loom. *Patent abandoned.*

829. A. H. and V. G. BELL. *An improved mode of constructing the armour of vessels of war.* Dated March 31, 1863.

In carrying out this invention, the inventors form the shot-proof covering of alternate lines of iron and wood, the interposed lines of timber being sufficiently narrow to ensure the adjacent iron bars intercepting any heavy shot that may strike the wood. The lines of iron are divided into bars of a convenient length. These bars are furnished at the back with projections welded on to them, which in pairs form jaws of a dovetailed shape at equal distances apart. Vertical ribs of the form hereafter described are let into the timber backing between the skin of the vessel and the armour, so that their exterior surfaces shall be flush with the front of the backing at intervals corresponding with the jaws on the armour bars. These ribs carry alternately on their face throughout their length a dovetailed form in cross section, corresponding in length with the depth of the iron bars, and for a length equal to the space between the iron bars a flange with parallel faces. The dove-tailed projections fit into the jaws of the armour bars, and the spaces between these projections allow of the jaws on the armour bars passing freely on and off the vertical ribs. The vertical ribs being fixed in their places and secured to the framework of the vessel by bolts, the armour bars are inserted in the spaces left for that purpose in the verticals, and lowered down until the jaws clip the dovetailed portions of the ribs, the intermediate timbers being built up alternately with the iron bars. Keys which clip the vertical ribs are driven in between the lines of bars, securing them firmly in their positions. The armour bars are arranged so as to break joint one above the other, by which means the armour becomes a self-supporting structure round the vessel. *Patent abandoned.*

830. R. A. BROOMAN. *Improvements in electric telegraph printing apparatus.* (A communication.) Dated March 31, 1863.

This invention is not described apart from the drawings. *Patent completed.*

831. E. O. COE. *Improvements in propellers for ships and other vessels.* Dated March 31, 1863.

This invention consists of one or more corrugated wheel or wheels made of metal, wood, or wood and metal combined, or of any other convenient substance. The corrugations radiate from the centre to the circumference, and the wheels may be wholly of solid metal, or may be of solid metal only to a certain depth from the periphery, having the more central part open or perforated. They are to be revolved by connection with machinery worked by any motive power, and may be applied at the sides of vessels as paddle wheels now are, or at the stem or stern, or both, or in any other convenient position. *Patent abandoned.*

832. H. HAMER. *Improvements in tanning, and in apparatus employed therein.* Dated March 31, 1863.

According to this invention, the hides or skins are suspended within an air-tight vessel, so that the tanning liquor which the vessel contains may come in contact with every part of each hide or skin. The patentee exhausts the air from the tank, and, further, keeps the tanning liquor in motion during the process, so as to prevent it separating, and so that it may sweep off from the hides or skins the film of spent liquor immediately it is formed. The apparatus employed for this purpose is a rectangular tank capable of being closed air-tight by a lid. Within this tank is a frame, somewhat shorter than the tank, and capable of moving to and fro endwise within it, this motion being given to it by a rod which is attached to the frame; the rod passes out through a stuffing box in the end of the tank, and is then connected with an eccentric or other similar instrument. The frame runs backwards and forwards within the tank on suitable guide rails, and the hides or skins are hung on laths at the upper part of the frame transversely of the length of the tank. As the hides or skins move to and fro, the tanning liquor presses first on one side of them and then on the other. The tank is connected with an air-pump, and is exhausted during the process. *Patent completed.*

833. J. M. DUNLOP. *Improvements in machinery for spinning cotton.* Dated March 31, 1863.

To that class of machinery known as Macarthy's gin, the patentee applies a cylinder or shaft with pegs or agitators placed near the point of contact of the gin roller and the knife or "doctor" on the feeding side of the gin, or it may be a cylinder with a vane or vanes set spirally or inclined to the axis. The shaft or cylinder above mentioned is carried in brackets or bearings secured to the framing of the gin, and may be used with or wihout a grated rack (hereafter referred to); or the shaft or cylinder may be carried by the ends of the grated racks described in the specification of a former patent (No. 1922), dated July 1, 1862, and in the latter case would move up and down with the grated rack. He, however, prefers the former. The shaft or cylinder above described is to have a suitable revolving motion given to it; or it may have one or more revolutions first in one direction and then in the other; or it may have an intermitent motion; or it may have a lateral motion. The object of these arrangements is to keep presenting the seed cotton to the action of the roller and knife that it may be more readily engaged thereby, and the seed separated from the cotton. The shaft or cylinder, in place of being provided with the same pegs or agitators as above described, may be a roller, either fluted, toothed, or covered, so that it will move the seed cotton and keep it in constant movement at the feeding part of the machine. The improvements may also be applied to the Roller Churka gin. One or both of the rails, described in the specification of the patent above referred to, and which carry the "doctors," in place of being applied as therein described, is or are made to swivel on pivots which fit into holes bored or formed in the frames. These rails with the "doctors" attached to them, when so made to swivel, are kept in their proper working position relatively with the curved rollers of the gin by set screws screwed into snugs cast with or formed on the framing, and they are thus caused to give the necessary pressure against the covered rollers. The top of the wood connecting rods and the moveable knife described in the specification of the aforesaid former patent, in place of being arranged and connected as therein described, have shoes applied, into which the wood connecting rods are fitted. These shoes are bolted to the moveable knife, and have projections downwards to admit of their being well secured to the wood connecting rods. A cross bar or projection is cast across each of the shoes, and a corresponding notch is cut out of each of the wood connecting rods, so that the strain does not entirely depend upon the bolts. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 23, 1863.

1576. A. R. Stocker, Wolverhampton, manufacturer. Improvements in preparing and fashioning iron applicable to the manufacture of boot heels, tips, and horse shoes, and in part of the machinery or apparatus to be employed therein.

Dated July 28, 1863.

1871. A. Hector, Montrose, gentleman. Improvements in means or apparatus for facilitating the catching of fish.

Dated September 2, 1863.

2165. M. Pinner, 12, South-terrace, Grosvenor-park, Camberwell. The manufacture of a flexible translucent material or fabric to be used as a partial substitute for glass. (A communication.)

Dated September 8, 1863.

2207. J. Burch, Cragg Works, near Macclesfield, engineer and manufacturer. Improvements in printing on curtain and other terry and velvet pile carpets, felted cloths, and other fabrics and materials, and in the processes and apparatus connected therewith.

Dated September 19, 1863.

2308. J. Fraser, 12, South-terrace, Grosvenor-park, Camberwell. An improved method of constructing magazines for the safer and more economical storing of volatile oils in localities where the ground and labour are expensive. (A communication.)

Dated September 24, 1863.

2360. H. A. Bonneville, 38, Porchester-terrace, Bayswater. Improvements in horse collars. (A communication.)

2361. H. A. Bonneville, 38, Porchester-terrace, Bayswater. Improvements in joining leather. (A communication.)

Dated September 26, 1863.

2375. E. B. Wilson, 5, Parliament-street, Westminster, civil engineer. Improvements in furnaces and fireplaces, applicable to the heating of steam boilers and other purposes.

Dated September 30, 1863.

2396. E. S. Attree, 37, Gibson-street, Waterloo-road, Lambeth. An improved cigar-holder. (A communication.)

Dated October 1, 1863.

2400. W. Smith, 4, South-street, Finsbury, London, civil engineer. An improved process for re-crystallizing sugar.

2402. T. Bell, Wishaw, Lanark, manager. A new mode of manufacturing bricks and tiles.

2403. H. A. Bonneville, 38, Porchester-terrace, Bayswater. Improvements in railway and other breaks. (A communication.)

2404. L. N. le Gras, Rathbone-place, Oxford-street, civil engineer. Improvements in cooking stoves and apparatus.

2406. J. Bell, Linton, Cambridge, civil engineer. Improvements in couplings for railway carriages.

2408. G. Dickey, Southwark, cabinet maker. Improvements in winkers or eye-screening apparatus for horses and other animals.

2410. T. Horsley, York. Improvements in breech-loading firearms.

Dated October 2, 1863.

2412. J. Farrar, Halifax, Yorkshire, machinist. Improvements in machinery or apparatus for spinning and doubling wool, alpaca, mohair, cotton, silk, flax, and other fibrous substances.

2416. J. G. Tongue, 34, Southampton-buildings, Holborn, engineer. An improved compound reactive agent and universal mordant to be employed in the processes of dyeing and printing. (A communication.)

2418. J. J. Lundy, Leith, colour and chemical manufacturer, and R. Irvine, Magdalen Chemical Works, Musselburgh, manufacturing chemist. Improvements in the manufacture of paper.

2420. G. T. Bousfield, Loughborough-park, Brixton. Improvements in revolver firearms. (A communication.)

2422. J. Bowron, South Stockton, Yorkshire, glass manufacturer, and G. Robinson, Welbeck-street, Cavendish-square. Improvements in the manufacture of soda.

Dated October 3, 1863.

2424. G. R. Tilling, Birkenhead, millwright, and J. Park, Liverpool, die and seal engraver. An improved mode or method of filling tobacco-pipes of an improved construction.

2426. T. and J. Fagg, Panton-street, boot makers. Improvements in the manufacture of boots and shoes.

Dated October 5, 1863.

2430. C. Brakell, W. Hochl, and W. Günther, North Moor Foundry Company, Oldham. Improvements in motive engines worked by water, steam, or other motive power. (Partly a communication.)

2432. O. Tomlinson, Grove Vale Cottage, Great Barr, Stafford, accountant. Improvements in taps, cocks, hydrants, or valves, and apparatus connected therewith, for opening, closing, regulating and facilitating and otherwise controlling the passage or flow of water, air, steam, gas, and other fluids and liquids.

2434. W. H. Bayley, Keighley, Yorkshire, mechanic. Improvements in machinery for combing wool and other materials. (Partly a communication.)

2438. J. Towlson, Heigham, Norwich, engineer. Improvements in apparatus for cooling liquids.

2440. W. Legg, Liverpool, hat and cap manufacturer. Improvements applicable to sewing machines.

Dated October 6, 1863.

2442. E. Whitehouse, Wolverhampton, manufacturer. Certain improvements in the manufacture of wrought-iron shackles.

2446. G. Dyer, Regent-street. Improvements in the construction of railway carriages.

Dated October 7, 1863.

2450. E. Leak, Longton, Staffordshire. Improved apparatus to be used in placing "glost" china and earthenware in ovens and kilns for firing, burning, or baking such ware.

2452. G. F. Graham, 1, Upper Gordon-street, Euston-square, surveyor and builder. Improvements in high pressure cocks.

2454. C. P. Button, 27, Leadenhall-street, merchant. Improvements in pumps. (A communication.)

2456. R. Zox, Nelson-square, Blackfriars-road, hat and cap manufacturer. Improvements in the manufacture of academic caps.

2458. E. Slaughter, Avonside Iron Works, Bristol, engineer. Improvements in locomotive engines.

2460. G. Whight, Ipswich, machinist. Improvements in washing apparatus. (A communication.)

Dated October 8, 1863.

2462. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in propelling ships and in the apparatus employed therein. (A communication.)

2464. C. Crosswell, 8, Salisbury-street, Strand. Improvements in breech-loading firearms. (A communication.)

2465. M. Smith, Bushfield-house, Donnybrook-road, Dublin. Improvements in washing, cleansing, salting, and packing butter, and in apparatus to be employed therein.

2466. G. Canouil, Paris, chemist, and F. A. Blanchon, Paris, manufacturer of toy arms. Shooting toy fusees, toy rockets, or other similar toy missiles, by means of toy pistols or other toy firearms.

2468. J. D. Dougall, 59, St. James's-street, Westminster. Improvements in "camel guns" and other light artillery, which improvements are also applicable to "punt guns" or other heavy fowling pieces or rifles.

2472. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in the construction of condensers. (A communication.)

Dated October 9, 1863.

2474. J. Wood, J. Whitehead, and T. Tetlow, Oldham, engineers. Certain improvements in machinery or apparatus for governing the speed of steam engines.

2475. J. Elsom, 10 and 11, Regent's-row, Dalston. Improvements in parallel turning, and in machinery for that purpose.

2476. E. W. James, Brynllys, Cardigan, farmer. Improved apparatus and arrangements for giving buoyancy to or raising sinking or submerged ships and other sinking or sunken bodies.

2478. J. McInnes, Liverpool, manufacturer of compositions for protecting the bottoms of iron ships. Improvements in sheathing for navigable vessels of iron or wood, which sheathing is also applicable to the covering of roofs, walls, and other purposes.

2481. N. Fellows, 123, Chancery-lane. An improved mode of extinguishing fires in chimneys and flues, regulating and promoting draught therein, calculated also to act as a ventilator.

Dated October 10, 1863.

2484. G. W. Reynolds, Smethwick, Staffordshire, crinoline manufacturer. An improved manufacture of bands or strips for crinolines.

2488. W. B. Fairbanks, J. Lavender, and F. Lavender, saddlers, ironmongers, bridle cutters, harness makers, &c., Walsall, Staffordshire. Improvements in the manufacture of hames.

Dated October 12, 1863.

2492. A. Inglis, 53, Arthur-road, Holloway. Improvements in taps or cocks, part of which improvements is applicable to the lubrication and protection of the journals of revolving shafts, axles, or spindles.

2494. W. Hutchison, 21, Cardigan-street, London. Improvements in the manufacture of fittings for powder flasks.

2498. T. Browning, Liverpool. Improvements applicable to metallic casks, and the machinery for the manufacture of the same.

2500. T. Fox, Ballingdon, near Sudbury. Improved apparatus for cleaning out the tubes of steam boilers, which apparatus is also applicable for cleaning out other tubes.

Dated October 13, 1863.

2506. J. Dodge, Waterford, New York, mechanical engineer. Improvements in machinery for rolling, shaping, or forging metals, and in apparatus for grinding and polishing the same.

2508. J. E. Poynter, Glasgow, chemical manufacturer. Improvements in throwing stone projectiles by means of explosive agents, and in apparatus therefor.

2509. J. Place, Hoddlesden, Lancashire, coal proprietor. Improved application of certain schistous or shaly materials to the manufacture and finishing of paper.

2510. A. Rolfe, Amwell-street, Pentonville, merchant. Improvements in means or apparatus for propelling carriages on railways, tramways, or on common roads.

2512. T. Scott, 31, Nelson-square, Blackfriars-road, engineer. Improvements in floating docks.

Dated October 14, 1863.

2516. J. Inchley, Birmingham, manufacturer. Improvements in valves for double cylinder steam engines.

2518. M. F. D. Cavalerie, 10, Rue de la Fidelité, Paris, mechanical engineer. Certain improvements in obtaining centrifugal motive power.

2520. W. J. Rideout, Farnworth Mills, Bolton, Lancashire, paper manufacturer. Improvements in boiling rags and other paper-making materials.

Dated October 15, 1863.

2525. P. Lesley, Philadelphia. Improvements in the manufacture of rails for railways. (A communication.)

2527. S. R. Smith, 7, Delamere-street, Paddington. Improvements in apparatus for connecting chain cables, and for clearing a ship's hawse when foul, and also in apparatus for acting on and preventing strain to the chain cables when ships are riding at anchor.

2529. B. F. Weatherdon, Kingston-on-Thames. A new apparatus for rubbing off or removing the dust or dirt from boots or shoes.

Dated October 16, 1863.

2531. J. Polglase, Bodmin, Cornwall, mine agent, and J. Cox, Manchester, agent. Improved apparatus for boring and cleaving stone.

2533. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in pumps to be worked by steam. (A communication.)

2534. F. A. E. G. de Massas, Hoxton, civil engineer. Improvements in smut machines, and in machines for cleansing and peeling grain and seeds.

2536. S. Jay, Regent-street. Improvements in the manufacture of stockings and drawers.

Dated October 17, 1863.

2537. M. Meisel, Park-walk, Brompton. Improvements in apparatus for ascertaining the weight of the load supported by the springs of railway locomotives and carriages for the purpose of regulating or equalizing such load. (A communication.)

2539. J. Shanks, Barrhead and Greenock, plumber. Improvements relating to water closet and other valves or taps.

2540. W. Hampson, jun., Dukinfield, Cheshire, overlooker. Certain improvements in looms for weaving.

2541. W. Routledge and F. F. Ommaney, Newbridge Foundry, Salford, engineers. Certain improvements in "baling boxes" used in packing cotton or other fibrous materials.

2542. W. Clark, 53, Chancery-lane, engineer. Improvements in rotary engines. (A communication.)

2544. W. Clark, 53, Chancery-lane, engineer. Improvements in sewing and embroidering machines. (A communication.)

2545. L. B. Chesbrough, Brooklyn, New York. An improved let-off motion for looms. (A communication.)

2547. W. Darlow, North Woolwich-road, and R. H. Lawson, Victoria-terrace, Victoria-docks. Improvements in apparatus or means for obtaining motive power.

2548. J. Wright, Esplanade, Rochester. Improvements in machinery for cutting railway sleepers to receive railway chairs.

2550. F. de Wylde, Trinity-square, Tower-hill. Improvements in the induration of stone, cement, stucco, brick, or other analogous materials, also in the manufacture of artificial stone.

2551. F. de Wylde, Trinity-square, Tower-hill. Improvements in the separation of molasses and other impurities from sugar crystals. (A communication.)

Dated October 19, 1863.

2552. J. Champion, Manchester, machinist. Improvements in machinery or apparatus for preparing, spinning, and doubling cotton, flax, wool, and other fibrous materials.

2553. W. Clark, 53, Chancery-lane, engineer. Improvements in separating ores from their gangues, and in apparatus for the same. (A communication.)

Dated October 20, 1863.

2559. J. Taylor, engineer, and J. and J. Lees, tin plate workers, Oldham. Improvements in machinery or apparatus for opening, cleaning, and mixing cotton or other fibrous materials.

2560. E. H. Luebbers, Liverpool, merchant. An improved treatment of textile substances to obtain a species of, or substitute for, cotton. (A communication.)

2561. W. Ingham, Manchester, and I. Wood, Pendleton, near Manchester. Improvements in the manufacture of copper rollers used for printing calico or other materials.

2563. D. Mills, Birmingham, manufacturer. An improvement or improvements in the manufacture of moulds for casting studs for chains.

2564. J. Vaughan, Birmingham, manufacturer. Improvements in the manufacture of picks, hoes, adzes, and other edge tools, and in tools to be used in the said manufacture.

2565. J. Michaelis, 3, Tower Royal, Cannon-street West, and 35, Aldersgate-street. Improvements in the manufacture of purses, pocket-books, and wallets, and in the construction of double-action locks for the same and other similar purposes.

2569. J. Bryant, Edgware-road, engineer. Improvements in vent apparatus for facilitating the drawing off or letting off fluids.

2570. H. B. Barlow, Manchester. Improvements in shoes, boots, and other coverings for the feet. (A communication.)

2571. W. A. Dixon, Glasgow, chemist. Improvements in making aluminate of soda and other aluminous salts.

2572. G. Davies, 1, Serle-street, Lincoln's-inn, civil engineer. Improvements in forming stitches over the edges of fabrics, and in machinery connected therewith. (A communication.)

2573. J. W. Nottingham, Clayton-place, Kennington-road, artist. Improvements in "Hansom cabs," parts of which improvements are also applicable to other wheeled carriages.

2574. G. H. Daglish and T. Windus, St. Helen's, Lancashire, engineers. Improvements in machinery for bending plates for iron ships and other like purposes.

2575. C. Garton, Bristol, brewer, and T. Hill, Southampton, sugar refiner. Improvements in evaporating, cooling, and melting, and in apparatus employed therein.

2577. T. Restell, Water-lane, Tower-street, London, engineer. An improved construction of walking-stick umbrella.

Dated October 21, 1863.

2578. W. Hartcliffe, Salford, machinist. Certain improvements in mules for spinning and doubling.

2580. J. Hinton, Birmingham, gun action filer. An improvement or improvements in breech-loading firearms.

2582. N. F. Taylor, 5, Manby-street, Stratford, gas engineer. Improvements in increasing the illuminating power of coal gas, and in the means or apparatus employed therein.

2583. G. Howell, Hawarden Iron Works, near Holywell, Flint. Improvements in apparatus for condensing metallic and other fumes.

2586. Z. Colburn, 3, Upper Bedford-place, Russell-square. Improvments in steam engines.

2590. J. Dodd, Oldham, machinist. Improvements in mules for spinning and doubling.

2591. W. E. Newton, 66, Chancery-lane, civil engineer. An improvement in sewing machines. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, November 3, 1863.

1550. C. Peterson. Manufacture of pipes or tubes.

1562. E. Wilks. Portmanteaus and trunks.

1576. A. R. Stocker. Preparing and fashioning iron.

1580. T. F. Parsons. Preparing plates, bars, or other objects of iron.

1590. T. Redwood. Straining or mixing and straining liquid and solid substances.

1591. P. R. Hodge. Improved fleeting hydrostatic machinery.

1592. E. Myers and W. R. Williams. Wet gas meters.

1595. T. Skinner. Ornamentation of silver, German silver, Britannia metal, electro-plated or other plated goods.

1596. A. E. Brae. Actuating domestic bells and other ...als by the electric current.

... T. Page. Horse shoes and fastenings.

... H. C. Lee. Sewing machines. (A communication.)

... Watson. Fastening.

1611. W. E. Gedge. Placing tyres on wheels or hooping or ferruling generally, while the metal is hot. (A communication.)

1612. J. Griffiths. Puddling iron and steel.

1614. T. Dunn. Construction and maintenance of the permanent way of railways.

1615. G. Clark. Construction of guns and projectiles.

1621. C. Avery. Rotary engines.

1622. L. E. Hicks. Inkstands.

1639. J. H. Johnson. Coating or covering metal sheets. (A communication.)

1644. J. and J. Cole. Looms for weaving.

1651. J. King. Hanging gates.

1657. H. Brinsmead. Cooking apparatus.

1659. H. S. Warner. Treating or preparing megass and other substances to be used as fuel.

1666. H. A. Bonneville. Steam engines.

1709. R. A. Brooman. Ships and propelling the same. (A communication.)

1734. M. W. Ruthven. Rudders or apparatus for steering ships.

1789. B. Lambert. Preparation of waste paper in order to its being again used.

1822. W. Clarke. Manufacture of fabrics.

1916. H. Woods. Regulating the temperatures during the process of fermentation in the "union cask," "tunning cask," or "cleansing cask."

2007. A. E. Brae. Conducting electric currents through railway trains, and actuating signals or alarums therein.

2092. A. Jobson. Drawing or discharging coke ovens and loading coke waggons.

2245. M. Gerstenhöfer. Roasting pyrites.

2447. A. Johnston. Railway carriages.

2464. C. Croswell. Breech-loading firearms. (A communication.)

2472. A. V. Newton. Construction of condensers. (A communication.)

2477. G. Parry. Refining crude pig iron.

2525. P. Lesley. Manufacture of rails for railways. (A communication.)

2540. W. Hampson. Looms for weaving.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed November 2, 1863.

1053. F. Bennett.
1110. J. Fortune.
1112. B. G. Sloper.
1116. W. Walsh.
1122. P. Bradshaw.
1124. W. Glover.
1127. T. Sagar and J. Wilkinson.
1130. S. Hibbert, J. Lawton, and J. Kay.
1131. S. D. MacKellen.
1132. I. M. Singer.
1135. A. Sturrock.
1138. J. Park.
1143. G. Bower.
1145. J. Bettridge.
1146. C. A. Day, A. Lamb, and T. Summers.
1149. P. J. Livsey.
1151. H. Schooling.
1153. C. L. Braithwaite and J. Hirst.
1154. J. H. Bailey.
1157. E. C. Bott.
1158. C. F. Bielefeld.
1160. W. Thomson.
1161. J. Stickland.
1164. J. Norie.
1173. C. H. G. Williams.
1179. C. S. and W. Shorrock.
1187. B. Lilly.
1201. T. Parkinson and F. Taylor.
1206. B. Lambert.
1230. J. Hinks.
1231. R. Talbot.
1234. J. T. Newton.
1267. J. T. Markall.
1296. S. E. Rosser and J. G. Jennings.
1338. G. Gore.
1487. I. G. and W. Bass.
1579. S. Robinson, J. Priestley, and J. Foulds.
1724. W. Clarke.
1753. L. M. Bournique and J. B. Vidard.
1754. L. M. Bournique and J. B. Vidard.
2108. T. Westhorp.
2320. W. Elsdon.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2640. T. Neal.
2652. J. Beck.
2656. J. H. Johnson.
2668. D. Joy.
2674. W. E. Newton.
2685. G. Hamilton.
2690. W. E. Newton.
2701. W. Edwards.
2717. W. Hewitt.
2718. T. W. Rammell.
2771. H. E. West.
3067. J. R. Cooper.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2539. T. S. Salt.
2547. J. T. Way.
2741. S. Fox.
2577. J. Nasmyth and R. Wilson.

THE MECHANICS' MAGAZINE.

Contents of the Last Number.—

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 13, 1863.

NON-CONDENSING ENGINES.

Probably one-half the number of stationary engines at work in Great Britain are without condensers; yet there are few complaints of their want of economy, although their use is by no means confined to those districts where coals are extremely cheap; many of them, indeed, being employed in driving mills, factories, and workshops in London, and large provincial towns where fuel is far from plentiful. The extended use of the non-condensing engine goes far to show that its defects have been much over rated, and its advantages too often kept in the background, by a class of engineers who believe that no steam engine is ever to be recommended unless it embodies some of James Watt's inventions in its construction. The fact is, that the wasteful consumption of fuel is so great, as a rule, in our steam machinery, that hundreds of expedients may be adopted which will equally secure a considerable saving, and the condenser is, after all, but one of these. There is no peculiar or occult benefit to be derived from its use, any more than there is from expansion, or high pressure, or a particular method of boiler-setting. The working of an engine with a defective generator may possibly he much improved by the application of a good arrangement for producing a vacuum, and it may still remain very much worse in every way than that of one better designed and constructed in other respects, yet without a condenser. The best kind of steam machinery is not that which depends for success on one good feature. It is to the skilful combination of many good things that we must ultimately be indebted for the attainment of a fair approach to theoretical perfection. It is erroneous to believe that that engine which burns least coal must invariably be the best. We have known colliery proprietors and mill-owners to put down steam machinery at a vast expense, which never paid one per cent. on the additional outlay, by the saving of fuel effected. Thousands of pounds have, ere now, been expended in the construction of reservoirs, culverts, and water-races, in order to supply the demands of a condenser; and this, too, in districts where steam coal of fair quality could be delivered on such terms that the saving effected by the vacuum would not amount to five shillings a day with an 80-horse engine. Economy of fuel, secured by such means, is frequently the most expensive item a manufacturer can invest in.

We do not wish our readers to imagine that we underrate the value of the condenser. Its presence will always be found beneficial, unless peculiar considerations imperatively dictate its absence; but we certainly consider it injudicious in the extreme, to resort to its use in situations where coal is so cheap, that but an insignificant saving can be effected by economy in its consumption; or where water is so distant, that much expense must be incurred before it can be brought in abundance to the engine-house pond. In these cases, it is pleasant to reflect that as good economical results may be, and have been, obtained from high-pressure non-condensing engines, as from any other description of steam machinery. We may cite the locomotive and the portable in proof of our assertion. On many of our great railway lines, the former performs its duties daily with a consumption of but 3·5 lbs. of good coal per indicated horse-power per hour; and any of our large agricultural engineering firms will guarantee a 20-horse portable to work up to that power for ten hours with 9 cwt. of coals, or even less; yet neither class work under circumstances favourable to economy. It is true that in many situations any parsimony in the first cost of steam machinery, or those items requisite to secure a saving in fuel, is injudicious in the extreme—as, for instance, in the case of sea-going ships, and in districts where fuel is scarce and dear; but even then the condenser can only be regarded correctly as an auxiliary, unable, alone, to effect greater results than those which can be produced individually, by good boilers, super-heated steam, high-pressure combined with expansion, and one or two other matters of minor importance. Hence we find the condensing engine not only holding its own, but, actually increasing in favour daily: its simplicity, small first cost, trifling consumption of oil and lubricants, and the slight expense incurred for repairs, rendering it a very general favourite; while the attention which has been devoted to it of late years, and the use of higher pressures, better pistons, and increased speeds, has gradually reduced the consumption of fuel so much, that it bears a very favourable comparison with condensing engines weighing and costing two or three times as much per indicated horse-power.

In comparing the merits of the two systems, it is necessary to remember that slow piston speeds will shortly become a thing of the past. Not only this, but the rotative velocity of our engines, is daily increased in the best practice; engineers and mill-owners finding it better to employ high-speed steam engines, rather than heavy and cumbrous intermediate gearing, to impart the requisite velocity to the driven machinery. Now, it is rather a difficult problem to work pumps successfully—that is to say, without excessive wear and tear of the valves and buckets, and much noise—when they are driven directly by engines running fast with a short stroke. The old-fashioned beam engine, with its costly paraphernalia of pump-rods and parallel motions, was designed far more with a regard to securing the correct action of the exhausting apparatus, than the mechanical properties which are indispensable to the attainment of a high result from the amount of steam passed through the cylinder. Simplicity of arrangement, and reduction in size and weight, were little valued; and steam as a motive power was absolutely unavailable before the introduction of modern improvements, in hundreds of situations where it is now employed with the greatest economy. The high-speed direct-acting engine of the present day, is, as a rule, just as unsuited to putting hydraulic machinery in motion, as the beam arrangement is admirably adapted to that end. A return to the old system is out of the question; and we must either consent to abandon the condenser altogether, or prepare to overcome obstacles, but too well understood by those who have to design our engines for driving the screw-propeller. We have little doubt that the time is not far distant, when the use of a condensing apparatus will be almost wholly confined to a class of steam machinery of the most refined construction, in which every other consideration will be sacrificed to the attainment of the highest possible useful effect from every pound of fuel consumed; such engines can only be required on board ship. The loss from blowing off, entailed by the use of sea-water, is so great, that the weight of a surface condenser and the requisite pumps, is as nothing compared to the weight of the coals saved by their use. It is true, that were high-pressure steam once introduced into our marine, the vacuum would at once lose half its value as a direct agent of economy. Its indirect value in securing a supply of fresh water to the boilers, would, however, be greater than ever; and in such situations, therefore, its use can never be legitimately abandoned. On land, a supply of fresh water to feed the boilers can always be obtained; and it is bad policy to complicate machinery, or reduce piston speed, merely for the sake of the few pounds additional pressure per square inch, which can be realised by a vacuum, obtained at last at an expense and trouble far greater than it is worth.

The value of a condenser depends almost wholly on the pressure of the steam employed. According as this is greater or less, so will the proportion of power derived from the vacuum represent anything, from the entire force of the engine, to a very small per-centage of the work done. Thus, an engine with a positive pressure of but 15 lbs. on the square inch of piston, would give out no useful effect whatever without the condenser. The safety valves of many of Watt's earlier boilers were loaded to but two or three pounds on the square inch, and his engines frequently worked with but 8 lbs. or 10 lbs. in their cylinders above the vacuum. In order to stop them, it was sufficient to exclude the injection. An engine of 100-horse power, working with 28 lbs. or 30 lbs. steam, will derive 50-horse power from the vacuum, and 50-horse power from the positive pressure of the steam; and in such a case, the suppression of the condenser would at once double the consumption of fuel. If 150 lbs. steam were used, however, the vacuum would produce but one-tenth of the power, and save only the same proportion of fuel, even admitting that it was theoretically perfect on the one hand, and that the resistance of the atmosphere to the motion of the piston was equal to its full pressure, on the other. Most probably neither assumption is correct; many engineers stating that the momentum of the escaping steam, is sufficiently great to cause a partial vacuum in the cylinder, if the waste-pipe is long and free from bends. Dr. Alban mentions an instance, where such a tube, constructed of thin sheet iron was crushed flat by the pressure of the atmosphere; while Mr. Scott Burn goes so far as to estimate the resistance to the motion of the piston at but 7 lbs. on the square inch, instead of 14·5 lbs.—a conclusion to which we take exception. A great diversity of opinion prevails as to the real value to be attached to the vacuum, after deducting the power required to work the air and cold water pumps, and to overcome the extra friction induced by their use. We have all heard of extraordinary vacuums, 29 inches of mercury, and so on. We recollect an instance, indeed, wherein we were gravely assured by an engineer that he had seen one of 60 lbs. on the square inch! A vacuum equivalent to 13 lbs. on the square inch is, perhaps, the greatest ever realized for any considerable space of time, and even this is met with only in the best engines, when the supply of condensing water is ample and the temperature low. From this we may safely deduct a pound, to compensate for the force required to put the pumps in motion, friction, &c.; and we thus find the useful effect of the condenser reduced, under the most favourable circumstances, to between 11 lbs. and 12 lbs. on the square inch. Add to this, the fact that condensing engines on land are seldom worked with high steam, while the slow motion of the piston gives time for an enormous amount of condensation to

take place in the cylinder, and we can easily understand how it is that the non-condensing engine can compete successfully with its more theoretically perfect rival. It is true that the condensing engine *could* be made superior to that working without a vacuum; but we are dealing with the question in its present aspect; and we must recollect that if one system is capable of improvement, the other is equally open to that desirable process, while the employment of the condenser is a positive obstacle to the attainment of that speed, extreme simplicity, and admirable facility for adaptation to the end in view, on which the practical perfection of steam machinery so much depends.

Until the principle of expansion is carried out much further than it has been as yet, we must continue to prefer the non-condensing system, so long as the price of coal is not excessive, in every case where water is not at hand in quantity or capital plentiful. A very little additional expense will secure a thoroughly good boiler, capable of carrying high steam with much greater safety than a low-priced one, with steam of half the pressure. A moderately-sized cylinder, carefully clothed, and a piston running at a high velocity, driven by 75 lbs. steam, cut off at one-fifth of the stroke, and slightly superheated, will give out a greater useful effect per lb. of coal than nine-tenths of the condensing-engines in every-day use in our manufacturing districts; while the first cost for foundations, piping, engine, and general fittings, will be reduced nearly one-half. It is of little consequence that the tenth engine is more economical. We may rest assured that that end is obtained at a considerable outlay, and by the sacrifice of many things for which, in all probability, the saving in fuel will hardly compensate. The non-condensing engine has been hitherto undervalued, and treated with a contempt which it certainly does not deserve. Had it received one-half the labour devoted to the condensing engine, it would now hold a very high position as a safe and economical motive power. We would willingly draw the attention of engineers to this class of steam machinery, convinced as we are that they will find in its improvement a fair and remunerative field for the display of their talents.

THE ORDNANCE REPORT, 1863, CONDENSED; AND CONCLUSIONS FROM IT.

No. I.

Report from the Select Committee appointed to inquire into the Expenditure incurred since the beginning of 1858 in various natures of improved Ordnance, whether obtained by contract or manufactured in the public departments, and also the results obtained by such Expenditure. Ordered by the House of Commons to be printed July 23, 1863.

For the charge of 16s. may be had, at the Parliamentary Papers Office, Abingdon-street, the Report of the Select Committee on Ordnance, 1863, an Encyclopædian folio, two inches thick, weighing 5 lbs., and containing nearly 700 pages, and 6,000 questions and answers, with numerous reports and diagrams relating to the construction, manufacture, properties, and cost of guns and projectiles, as well as reports of experiments and the history of the Armstrong transaction. It is a valuable contribution to the science of gunnery, furnishing data and evidence, from which conclusions may be drawn useful to engineers, manufacturers, and artillerists, and highly beneficial to the public interest. Few persons will have the leisure or inclination to read and digest the mass of matter which the huge tome contains. Hence the public are left to form their opinion of the nature and result of the investigation from the analysis of partizan or party writers, who select such parts of the evidence as tend to establish their own objects, theories, or views, and either suppress or gloss over whatever is in opposition to the particular case they wish to prove.

To appreciate and draw correct conclusions from the evidence, to separate the grain from the chaff, is a work of patient research; but the results will repay the labour; and no doubt a condensed *resumé* of the report, in its different aspects, will be acceptable to that large professional and scientific body of men who take an interest in the gunnery question, than which none is of higher national importance.

The Select Committee, it is stated, was appointed "to inquire into the Expenditure incurred since the beginning of 1858, in various natures of improved Ordnance, whether obtained by contract, or manufactured in the public departments, and into the results obtained by such Expenditure." The real purpose of the inquiry was to investigate the circumstances connected with the Armstrong contracts and appointments; but this investigation extended into so wide a field, that it embraced every branch of gunnery, and has been the means of eliciting and registering facts and opinions of much value in every point of view. These have been carefully analyzed and will be presented to the reader in a condensed form under the heads they respectively belong to.

Before entering into the matter, we deem it right to state our impression with reference to the main object for which the Select Committee was appointed by the House of Commons, and we have no hesitation in saying, that the effect of a careful perusal of the voluminous contents of the Report, on any candid and unbiassed mind, would be that the evidence, unmistakeably condemns the Armstrong system of artillery, and censures the Government authorities for its adoption into the service.
